Methods: We used a wild-type Canton S genomic λ phage library[14] to walk[7] approximately 30 kb from the distal edge of the 37C1,2 *Ddc* region, isolated by Hirsch and Davidson[6], to the dl^H breakpoint. A restriction fragment from the phage spanning the breakpoint was then used to screen a recombinant λ phage library prepared from $In(2L)dl^H/CyO$ (ref. 15) fly DNA. The dl^H and dl^T breakpoints were mapped more precisely by using specific restriction fragments from the phage D1 (see Fig. 4*a*) as probes to compare the DNA sequence organization of the two inversions with that of the wild-type parental chromosome in which the inversions have been induced. In the autoradiograph, the DNAs were digested with *Hin*dIII and after gel electrophoresis and blotting, probed with the 2.3-kb *Hin*dIII–*Sst*I fragment from phage D1 (see Fig. 4*a*). In the wild-type parental DNA, fragment 5 hybridizes to a 3.9-kb *Hin*dIII fragment that is missing in both inversions. Two new fragments of 5.5 and 3.6 kb are found in dl^T, while in dl^H there are two fragments of 8.0 and 5.0 kb. *In situ* hybridization was performed using the method of Pardue and Gall[16].

Genetic studies[2,4] have shown that *dorsal* is expressed in females and that the gene product is required during early embryogenesis but does not appear to be essential at later stages in the *Drosophila* life cycle. Therefore, we examined the stage and tissue distribution of the *dorsal* RNA. For this purpose, poly(A)$^+$ RNA was prepared from adult males and females, dissected ovaries, and staged embryos: 0–2.5-h (cleavage and early blastoderm), 2.5–5-h (blastoderm and gastrula), 8–10.5-h (post-gastrula) and 20–24-h embryos collected at 22 °C. Northern blots of these RNAs were then probed with restriction fragment 8 from the *dorsal* gene (see Fig. 4*a*), or with a recombinant containing the 5*C* actin gene[8].

Figure 5*a* shows the developmental profile of the 2.8-kb *dorsal* RNA. We did not detect the *dorsal* transcript in adult males (lane 1) or females (lane 2). Conversely, as expected from genetic studies, the RNA was present in dissected ovaries (lane 3), suggesting that the expression of the *dorsal* gene in adult females may be restricted to ovaries. The *dorsal* RNA is also found immediately after fertilization in the 0–2.5-h cleavage and in early blastoderm embryos (lane 4). Interestingly, this RNA is apparently degraded as it is not detected in either 2.5–5-h embryos (lane 5) or 8–10.5-h embryos (lane 6). In 20–24-h embryos (Fig. 5*a*, lane 7), there are poly(A)$^+$ RNA-containing sequences complementary to the *dorsal* probe. This RNA species is present in low yield and as its mobility appears to be slightly different from that of the 2.8-kb *dorsal* transcript, we are uncertain at present whether it represents a bona fide *dorsal* transcript, or some other RNA which contains homologous sequences.

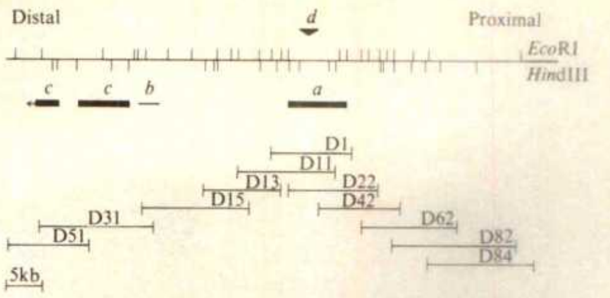

Fig. 3 Restriction map of the *dorsal* region, transcribed regions and chromosomal breakpoints. The D1 to D84 recombinant phages are shown. *a*, *dl* transcript; *b*, location of the distal *Df(2L)TW119* breakpoint; *c*, adjacent transcription units; *d*, location of breakpoints of $In(2L)dl^H$ and $In(2L)dl^T$.

Methods: Overlapping recombinants were isolated from a Charon 4, λ phage library of Canton S genomic DNA[7,14]. Chromosomal breakpoints were localized by hybridization of radioactively-labelled[17] recombinants or isolated restriction fragments to Southern[18] blots containing genomic DNA[19]. Coding regions were identified by hybridizing radioactively-labelled recombinants or isolated restriction fragments to Northern blots containing total or poly(A)$^+$ RNA from early embryos.

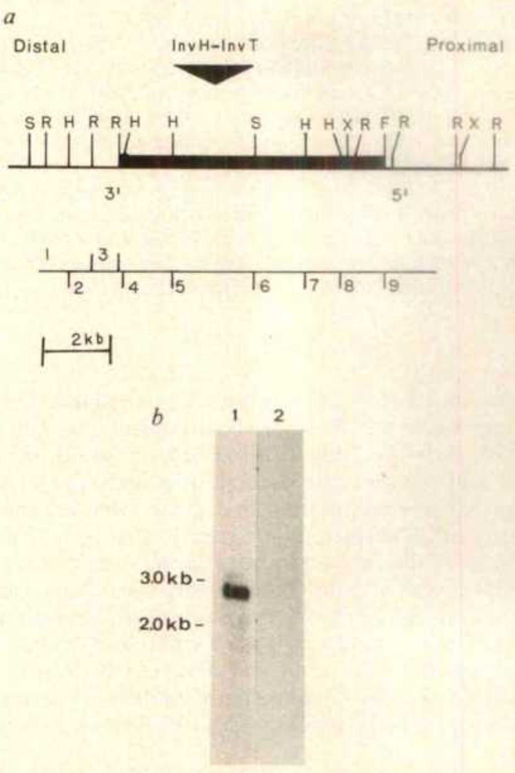

Fig. 4 *a*, Restriction map, transcribed region and chromosomal breakpoints of the *dorsal* gene. R, *Eco*RI; H, *Hin*dIII; S, *Sst*I; *F*, *Sal*I; 1–9, restriction fragments which were isolated and used for hybridization. *b*, The *dorsal* transcript and orientation of transcription. Lane 1, the 2.8-kb *dorsal* transcript. Poly(A)$^+$ embryonic RNA was hybridized with the complementary radioactively-labelled strand of the single-strand recombinant mp8-8. Lane 2, poly(A)$^+$ embryonic RNA hybridized with the complementary radioactively-labelled strand of the single-strand recombinant mp9-8. The size markers were the 3.05-kb, molecular weight (MW) 83,000 heat shock protein mRNA[20] and the 1.95-kb actin mRNA[8].

Methods: Poly(A)$^+$ RNA was isolated from 0–3-h embryos according to the method of O'Hare *et al.*[21], and Northern blots containing this RNA were hybridized with probes containing the *dorsal* coding region and plasmids containing coding sequences for the MW 83,000 heat shock protein or for actin. Fragment 8 was subcloned in opposite orientation into the M13 single-strand vectors mp8 and mp9. Strand-specific radioactively-labelled probes were synthesized[22] and hybridized to Northern blots.

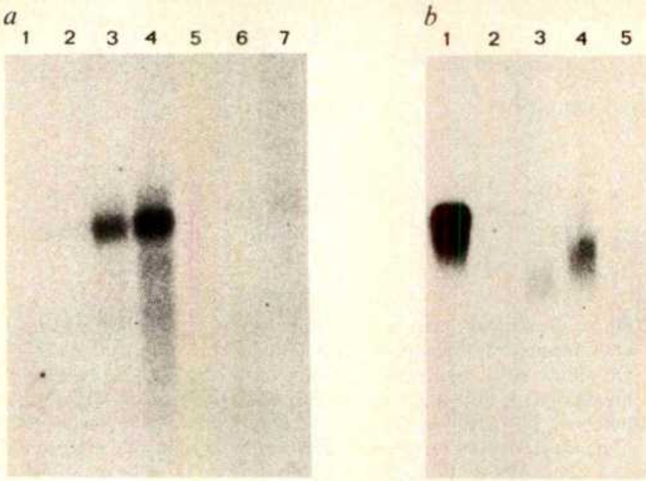

Fig. 5 *a*, Transcripts of the *dorsal* gene during embryonic development. All lanes contain 5 μg of poly(A)$^{+}$ RNA. Lane 1, adult male; lane 2, adult female; lane 3, ovary; lane 4, 0–2.5-h embryo; lane 5, 2.5–5-h embryo; lane 6, 8–10.5-h embryo; lane 7, 20–24 h embryo. *b*, Transcripts of the *dorsal* gene in ovaries from dl^{H} and dl^{T} females. Lane 1, wild-type ovary poly(A)$^{+}$ RNA (5 μg); lane 2, $In(2L)dl^{H}/Df(2L)TW119$ ovary poly(A)$^{+}$ RNA (5 μg); lane 3, $In(2L)dl^{H}/Df(2L)TW119$ ovary total RNA (20 μg); lane 4, $In(2L)dl^{T}/Df(2L)TW119$ ovary total RNA (20 μg); lane 5, $In(2L)dl^{T}/Df(2L)TW119$ ovary poly(A)$^{+}$ RNA (5 μg). The Northern blots were hybridized with fragment 8 (see Fig. 4*a*).
Methods: The RNA samples were run on formaldehyde agarose gels and blotted[23]. After exposure to X-ray film, the filters were rehybridized with a recombinant plasmid (pDmA2) containing part of the coding region of the 5C actin gene[8]. In the Northern blot shown in *a*, low levels of actin message were seen in the lanes containing adult RNA, but consistently high levels were observed in ovaries and during embryogenesis. In the Northern blot shown in *b*, equally high levels of full-length actin message were found in all poly(A)$^{+}$ lanes (results not shown).

To test the integrity of the RNAs, we determined the level of actin message in the different RNA preparations. Although, as expected, there was little actin message in adults, the level in ovaries and during embryogenesis was high and very nearly constant[8]. These results show that the *dl* gene is expressed in the ovary and that there is a dramatic change in the relative abundance of the *dorsal* transcript during early embryogenesis.

The amount of actin mRNA in embryos has been determined by Anderson and Langyel[9], making it possible to estimate the number of *dl* transcripts in 0–2.5-h embryos by comparing the signal intensity of the actin and *dl* RNAs in Northern blots. The *dl* RNA is about 100 times less abundant than actin mRNA and this would correspond to $\sim 5\times10^{4}$ *dl* RNA molecules per embryo.

Because the breakpoints of dl^{H} and dl^{T} are located within the transcription unit for the 2.8-kb RNA, it was of interest to determine whether these mutations affect the transcription of the *dorsal* gene. RNA was prepared from ovaries of females carrying either of the inversion chromosomes over $Df(2L)TW119$. Total and poly(A)$^{+}$ RNA isolated from the mutant ovaries was hybridized with fragment 8 (Fig. 4*a*) from the *dorsal* transcription unit (see Fig. 5*b*). Poly(A)$^{+}$ RNA from wild-type ovaries gives a strong hybridization signal with the dorsal probe (lane 1 of Fig. 5*a*). In contrast, little or no hybridization can be detected in poly(A)$^{+}$ RNA prepared from dl^{H} (lane 2) and dl^{T} (lane 5) ovaries, indicating that these two mutants fail to synthesize the 2.8-kb *dorsal* transcript. Nevertheless, the *dorsal* gene appears to be transcribed in ovaries from both mutants as we observe aberrant poly(A)$^{-}$ RNA species of smaller molecular weight in total RNA (lanes 3 and 4). In a control experiment, RNAs from the two inversion and wild-type ovaries were hybridized with phage D31 which contains the two transcription units distal to the $Df(2L)TW119$ breakpoint (see Fig. 2). As the expected full-length RNAs were found (results not shown) it is unlikely that these distal transcription units (*c* in Fig. 3) are part of the *dorsal* locus.

Here we have described the isolation and characterization of a 75-kb DNA segment from the cytogenetic interval 36C on the left arm of chromosome 2 which contains the *dorsal* locus of *D. melanogaster*. Of the three transcription units identified in the 75-kb *dorsal* region, two map outside the deficiency $Df(2L)TW119$, and are unlikely to be part of the *dorsal* locus. The third transcription unit, which is 8 kb long and encodes a 2.8-kb poly(A)$^{+}$ RNA, lies within the region deleted by $Df(2L)TW119$. This conclusion is based on the finding that inversions dl^{H} and dl^{T}, which are *dorsal* mutations, have breakpoints that disrupt the 8.0-kb transcription unit. Moreover, the 2.8 kb-poly(A)$^{+}$ RNA transcript is absent in ovaries of these mutants, and instead they produce smaller, truncated poly(A)$^{-}$ RNA transcripts from the beginning of the *dorsal* gene.

Although we observe high levels of the 2.8-kb *dorsal* transcript in both dissected ovaries and cleavage-stage embryos, it seems likely that the *dorsal* gene may be transcribed only during oogenesis. First, genetic studies have shown that *dorsal* is not zygotically rescued by wild-type sperm[2]. Second, molecular studies indicate that there is little or no transcription until development of syncytial blastoderm[10,11]. Although the *dorsal* gene is probably not transcribed in early embryos, it is possible that the maternally derived RNA is translated during the initial phase of embryogenesis. Zalokar[10] has shown that translation of stored maternal message starts immediately after fertilization. If the *dl* RNA is translated at this time, this process must be completed before cellular blastoderm formation because the RNA is absent at this stage. Also, the activity of the *dorsal* gene product is presumably required before formation of cellular blastoderm as embryonic polarity seems to be irreversibly determined by that stage[4,12].

The *dorsal* phenotype can be partially rescued by injection of cytoplasm from wild-type cleavage-stage embryos into mutant hosts of the same age[3,4]. The rescuing activity is found on both the dorsal and ventral sides of the wild-type embryos immediately after fertilization and becomes localized in the ventral sides during cleavage[3]. Note that *dorsal*, unlike several other 'dorsalizing' mutants, cannot be rescued by the injection of RNA from early embryos (see accompanying paper[13]). This result is surprising in view of the apparent abundance of the *dl* RNA at this stage. Conceivably, insufficient active *dl* product is synthesized from the injected *dl* RNA. Alternatively, the product either may not function properly or may not be correctly localized. Clearly, it will be of interest to determine how the *dorsal* product (transcript or protein) becomes assymetrically distributed and to study its role in the establishment of dorsal–ventral polarity.

We thank J. Hirsch for providing the recombinant phage from which the cloning work was begun. We also thank E. Fyrberg for the actin clone, Le Nguyen for technical assistance, K. O'Hara for typing the manuscript, and our colleagues, especially Drs D. Coulter and S. Tsubota, for helpful discussions. R.S. also thanks C. Nüsslein-Volhard for her advice and support in the early stages of this work. This work was supported by grants from the NIH and the March of Dimes Birth Defect Foundation.

Internal control of the coated vesicle pp50-specific kinase complex

Alain Pauloin & Pierre Jollès

Laboratory of Proteins, University of Paris V,
45 rue des Saints-Pères, 75270 Paris Cedex 06, France

The polyhedral surface lattice of coated vesicles consists of three-legged hexameric protein complexes called triskelions which constitute the basic assembly unit[1]. The triskelion is a molecular complex of molecular weight 630,000 (M_r 630K) composed of three clathrin heavy chains (subunit 180K) and three light chains (subunits 33K and 36K) (refs 2, 3). The presence of additional coated vesicle-specific proteins in the 100–130K and 50–55K range have been reported[4–6]. We previously described the presence of a cyclic nucleotide- and Ca^{2+}-independent protein kinase activity in coated vesicles[7] which was confirmed by others[8,9]. This protein kinase specifically phosphorylates the 50K protein (pp50). In this report, we show that the coated vesicle kinase and its 50K protein substrate are part of a stable multimolecular system. In addition we show that the clathrin–light chain complex stimulates the pp50 phosphorylation and only light chains are implicated in this stimulation and that the pp50 phosphorylation does not seem to be affected by the vesicle.

Coated vesicles were dissociated in a 1 M Tris-buffer, *p*H 7, and applied to a Sepharose CL-4B column[10]. Three peaks (I to III) were characterized (Fig. 1). Peak I contained decoated vesicles. Clathrin with its light chains (triskelions) were the main components of peak II. Peak III contained no clathrin but was greatly enriched in the 50 K protein (pp50) associated with a family of at least six proteins with molecular weights in the range 105–136 K. The most abundant protein was M_r 105K, whereas the others seemed to be present in equal amounts (Fig. 1*a*, III). By comparison with a standard curve prepared with marker proteins, the elution volume of peak III in the Tris buffer corresponded to that of a 400K globular protein. Coated vesicle kinase activity was always present in this peak (Fig. 1*b*, III). The over-exposed autoradiography shows the absence of other phosphorylations in both the decoated vesicle and triskelion fractions (Fig. 1*b*, I and II). The enzymatic activity was stable. In the presence of phenylmethylsulphonyl fluoride (PMSF), a protease inhibitor, activity was preserved for several months in the 1 M Tris-buffer, *p*H 7, at 4 °C or indefinitely at −30 °C in 50% glycerol.

Chemical cross-linking of the previously phosphorylated molecular complex of peak III with dimethyladipimidate (DMA) indicated that pp50 is closely associated with some proteins of the 105–136K group, and forms a 330K labelled complex. No new band appeared in the 100 and 150K regions of the gel suggesting the absence of a pp50 dimer and trimer. Very high molecular weight cross-linked complexes, in particular a 660K complex, were only observed for DMA concentrations above 0.4 mg ml^{-1} (Fig. 2).

We studied the possible interaction of either the triskelions or the decoated vesicles on the kinase activity of the 105–136K complex. Increased concentrations of triskelions had a stimulating effect on pp50-kinase activity. The latter increased the pp50 phosphorylation approximately 4-fold. The light chains seemed responsible for this stimulation, as clathrin had only a very slight effect (Fig. 3). On the other hand, decoated vesicles seemed to inhibit the pp50 phosphorylation, but lost their inhibiting effect when heated (Fig. 3). The inhibition was due to the ATP consumption induced by the ATPase activity present in the decoated vesicles (data not shown).

Keen *et al.*[10] have shown that coated vesicles are dissociated after treatment with protonated amines at neutral *p*H. Gel filtration of their coated vesicle–Tris extract allowed separation of the triskelion fraction from another fraction, described as the basket assembly factor, containing a 110K protein and eluting in a volume corresponding to a molecular weight of 420K. There is a good parallel between this isolation of the basket assembly factor and the kinase-specific substrate complex of coated vesicles. The co-purification of these two biological activities raised the question of whether they share a common molecular support.

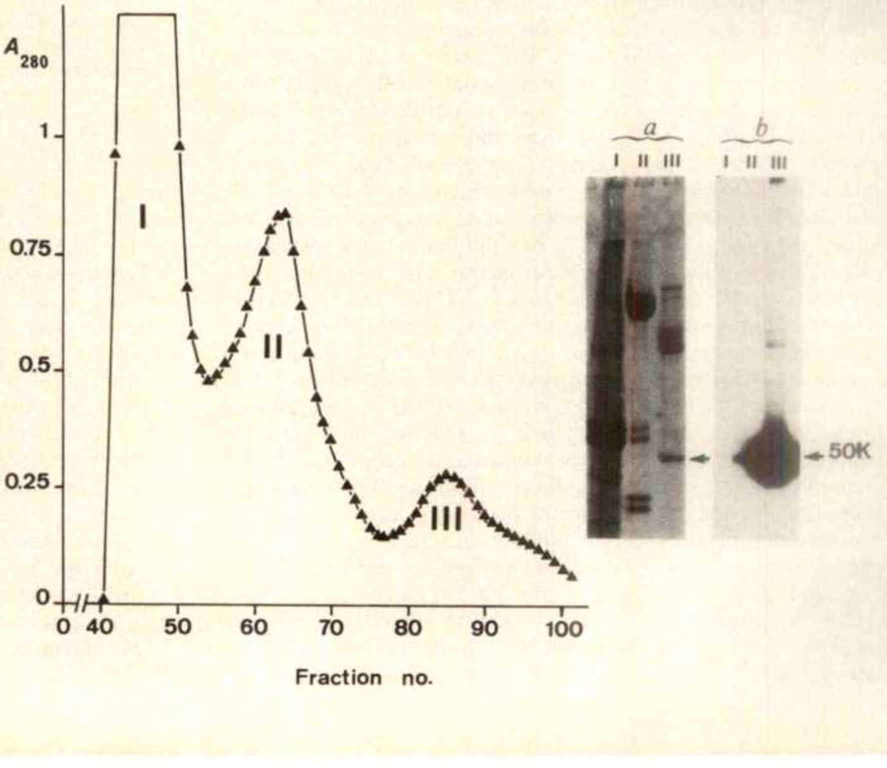

Fig. 1 Gel filtration of Tris-dissociated coated vesicles on Sepharose CL-4B. The gels after Coomassie blue staining *a* and autoradiography *b* are shown in the inserts.
Methods: Coated vesicles were isolated by two successive sucrose gradients[7,10]. The highly enriched upper 5% sucrose solution of the second gradient was used for the final purification using a $^1H_2O/^2H_2O$-8% sucrose step gradient as described[20]. The coated vesicle pellet (50 mg) was solubilized in 3 ml of 1 M Tris buffer, *p*H 7.0, 0.1 mM EGTA, 2 mM $MgCl_2$, 1 mM 2-mercaptoethanol, using a Potter homogenizer, incubated for 30 min at room temperature and applied to a column (2.5 × 120 cm) of Sepharose CL-4B equilibrated and eluted at 20 °C with the Tris buffer. Fractions of 4.5 ml were collected at a flow rate of 22.5 ml h^{-1}. The column was calibrated with ferritine (364K), catalase (240K), human γ-globulins (150K) and albumin (67K). The most enriched fractions of each peak (No. 45, 62, 85 for peaks I, II and III, respectively) were dialysed against 50 mM Tris buffer, *p*H 7.0. Aliquots (30 μl) were taken, phosphorylated with 10 μCi [γ-^{32}P]ATP (specific activity ≃ 3,000 Ci mmol^{-1}) and analysed by SDS-PAGE; autoradiography was performed as described elsewhere[7].

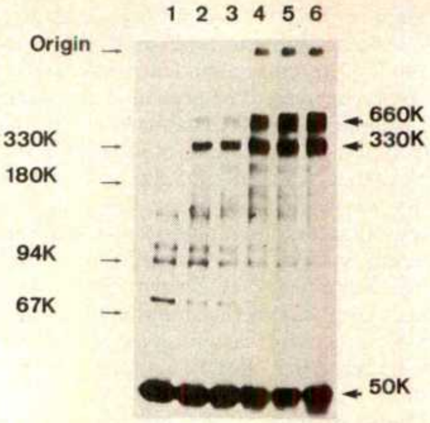

Fig. 2 Cross-linking by the bifunctional reagent dimethyladipimidate (DMA) of the 50/105–136K [^{32}P] molecular complex. Lane 1, purified [^{32}P] 50/105–13K complex without DMA; lanes 2–6, experiments carried out with DMA at 0.2, 0.4, 0.6, 0.8 and 1.0 mg ml^{-1}.

Methods: Cross-linking experiments were performed at room temperature with DMA (Sigma). This reagent was used, in the same conditions as dimethylsuberimidate[21], because it reacted more gently with our material. Cross-linking was performed as follows: 1 vol of 1 M triethanolamine (*p*H 8.5) was added to 4 vol of phosphorylated 50/105–136K molecular complex (0.1 mg ml^{-1}) in 50 mM Tris (*p*H 7.0). DMA was dissolved in 0.5 M triethanolamine (*p*H 8.5) at 15 mg ml^{-1}, and an appropriate volume was added within 1 min to the protein sample in order to obtain a final concentration between 0.2 and 1 mg ml^{-1}. The cross-linking reaction was carried out for 1 h at 25°C, then the cross-linked compounds were analysed by SDS-PAGE and autoradiography.

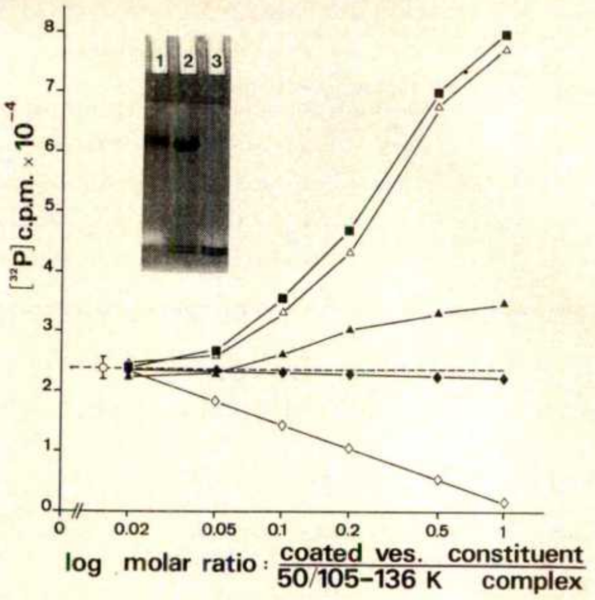

Fig. 3 Action of coated vesicle constituents on the pp50 phosphorylation. Results were expressed as the molar ratio of the concentration of triskelions (■), clathrin (▲), light chains (△), native decoated vesicles (◇) or heated decoated vesicles (◆), to the 50/105–136K molecular complex concentration. Phosphorylation level of the pp50 without effector was indicated (----). Control analysis of both the clathrin and light chains by SDS-PAGE is shown in the insert. Lane 1, clathrin, lane 2, triskelions, lane 3, light chains.

Methods: Decoated vesicles (peak I), triskelions (peak II) and the 50/105–136K complex (peak III), obtained as described (Fig. 1), were dialysed against 50 mM Tris, *p*H 7.0. Dialysed triskelions were concentrated (to ~1 mg ml^{-1}) and divided into three equal fractions. One of these constituted the triskelion sample and was stored at −30 °C in 50% glycerol to prevent proteolysis before using. The second fraction was used to prepare pure clathrin by spontaneous proteolysis of light chains. Their hydrolysis was generally complete after one week at 4 °C. The third fraction was used to prepare pure light chains by thermal denaturation of clathrin as described[17]. Decoated vesicles were divided into two equal fractions. One of these was heated at 50 °C for 5 min, the second was the native decoated vesicles. The protein concentrations[22] were determined before the reassociation experiments. The 50/105–136K complex (15 μl at 75 μg ml^{-1}) was mixed on ice with either 15 μl of various dilutions of triskelions (440 μg ml^{-1}), clathrin (360 μg ml^{-1}), light chains (75 μg ml^{-1}), native decoated vesicles (1,130 μg ml^{-1}) or heated decoated vesicles (1,130 μg ml^{-1}). The pp50 phosphorylations were carried out as previously described[7] and analysed by SDS-PAGE. After Coomassie blue staining, destaining and drying, the 50K bands were cut from the gel and counted by liquid scintillation.

There is no doubt that more than one component was present in the so-called "100–110K band" as shown using SDS-polyacrylamide gel electrophoresis (PAGE) by many authors[1,6,10–13]. Pfeffer and Kelly described a family of one major and seven minor polypeptides in this zone[5]. We agreed with these results and observed one major 105K protein and at least six minor polypeptides from 105K to 136K (ref. 14). This protein complex, whose total molecular weight including all its components, exceeded 1,000K was made up of at least two molecular complex systems possessing the same elution volume corresponding to M_r 400K. One of them might constitute the basket assembly factor (although its molecular composition remains unknown), the other was shown by cross-linking experiments, which demonstrate that pp50 is in close contact with some other proteins, to form a 330K cross-linked compound. Finally the ATP-independence of both the *in vitro* coated vesicle association and dissociation phenomena seemed to indicate that the basket assembly factor was distinct from the kinase-pp50 substrate complex. The phosphorylation of pp50 was under control of several components of the coated vesicles as shown by reassociation experiments. Phosphorylation was greatly enhanced in the presence of triskelions, where the light chains seemed to play the main role. Recently light chains have been shown to contain tightly bound nucleotides (AMP and/or ADP). However, storage of light chains at 4 °C for several days resulted in a large decrease of ADP and an increase in the level of AMP; it appeared that nucleotide hydrolysis had occurred and that ATP was possibly the original bound nucleotide[15]. The presence of this light chain nucleotidic site might facilitate both the ATP capture and its transfer to the kinase and could explain the stimulating effect of the light chains on the pp50 phosphorylation. The light chains have so far been implicated in the cage reassociation[1,6], but recently Winkler and Stanley[17] have suggested that this is not the case. In this present work a biological function related to the light chains has been shown.

The decoated vesicles did not seem to directly inhibit the pp50 phosphorylation. We verified that the apparent phosphorylation inhibition was induced by the previously described vesicular ATPase(s)[12,18,19]. However, the local ATP concentration might be modulated by the vesicles and thus, indirectly regulate the pp50 kinase. It should be noted that the strong ATPase action observed in decoated vesicles was only very slight in native coated vesicles. It is possible that the Tris-dissociating action induces the exposure of some cryptic forms of the ATPases or umasks these enzymes.

Although at present the physiological function of the pp50 phosporylation remains unclear, this activity is present in various different coated vesicle species we have studied[14]. Its activation by triskelions seems to indicate that the pp50-kinase system might be implicated in the control of the coated vesicle working mechanism involving both the membrane and clathrin coat fusion and fission. As we have shown that pp50 phosphorylation is under the positive control of the light chains, a negative control by another part of the coated vesicles or by external stimuli might also exist.

This research was supported by CNRS (ER no. 102) and INSERM (U-116). We thank Dr Fevre (CNRZ) for providing the bovine brains, and Dr I. Bernier (INSERM U-116) and Mrs A. Kropfinger (University of Paris VII) for helpful comments. A part of this work was presented as a poster at the symposium "Médiateurs intracellulaires et phosphorylation des protéines", 5–7 May (1983), Montpellier, France.

A six-armed oligomer isolated from cell surface fibronectin preparations

Harold P. Erickson & José L. Inglesias

Department of Anatomy, Duke University Medical Center, Durham, North Carolina 27710, USA

Fibronectins are adhesive glycoproteins thought to mediate the attachment of cells to various substrates[1,2]. Plasma fibronectin (PFN) is a dimer comprising subunits of molecular weight 220,000, connected by one or two disulphide bonds. Electron microscopy shows that PFN is a long, flexible strand, 2–3 nm in diameter and 140 nm long[3,4]. Many cells in tissue culture elaborate an extracellular matrix of insoluble (highly cross-linked by disulphide bonds) fibronectin, and a variable amount of 'cell surface fibronectin' (CSFN) that can be extracted by mild urea treatment. This CSFN, soluble in 1 M urea and at high *p*H, is a mixture of dimers and disulphide-bonded oligomers[5–7]. In the present study we have examined the structure of these molecules by electron microscopy. Oligomers were separated from dimers and contaminating proteins by zone sedimentation through glycerol gradients. We report that the CSFN dimers are identical in structure to PFN. In contrast, the oligomers have an elaborate and well defined structure that we call a 'hexabrachion': six arms emanating from a central globular particle. The arms are similar to PFN in being long, thin and flexible, but have several distinctly different features.

Figure 1 shows the results of SDS-gel electrophoresis of human CSFN fractionated by gradient sedimentation. The only prominent bands were peptides with apparent molecular weights (MWs) of either 285,000 (285K) or 240K, depending on the position in the gradient. The 285K peptide was found in fractions sedimenting at ~13S (Fig. 1, lanes *d, e*), and the 240K peptide in 9S fractions (lanes *g–i*). The 240K molecular weight of the 9S fraction corresponds to the value previously reported for unfractionated human CSFN[8]. The 285K peptide, which can be seen as a faint band in the crude CSFN (Fig. 1, lane *b*), as well as in the oligomeric fractions, has not been reported previously. Note that the amount of oligomeric material varied considerably, and was greatly reduced in older cultures (> 20th passage); this might explain why the 285K band has not been reported previously.

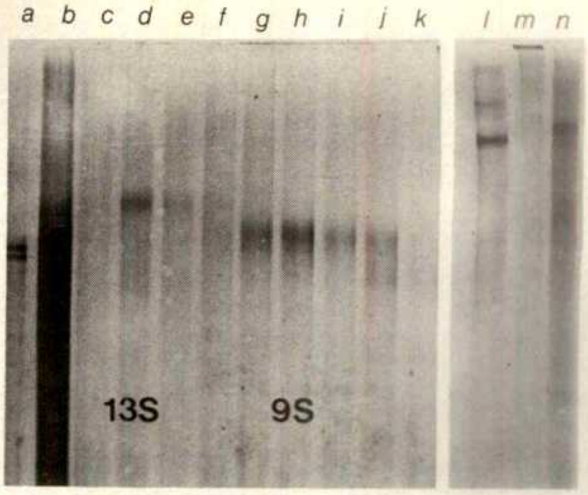

Fig. 1 Analysis of cell surface fibronectin (CSFN) after glycerol gradient sedimentation. CSFN was prepared from cultured human fibroblasts (foreskin, passage 16–18), grown on pads of glass wool in Petri dishes (J.L.I. and H.P.E., in preparation), 2 weeks after subculture. Cultures were extracted with 1 M urea, then CSFN was precipitated with 70% ammonium sulphate and resuspended in 0.15 M NaCl, 10 mM $CaCl_2$, 10 mM cyclohexylaminopropane sulphonic acid, *p*H 11.0 (ref. 5). A 0.5-ml volume of CSFN was layered onto a 12 ml gradient of 15–40% glycerol in 0.2 M ammonium bicarbonate, *p*H 9.5. The gradients were centrifuged at 41,000 r.p.m. for 18 h at 20 °C in a Beckman SW-41 Ti rotor, and 20 fractions of 0.6 ml each were collected. Samples (40 μl) were run on a 5% polyacrylamide gel by the method of Laemmli[12], and the gel was stained by the silver technique[13]. Lanes *a–k* contained β-mercaptoethanol, and lanes *l–n* were run (on the same gel) in non-reducing conditions. *a*, Human PFN (1.25 $\mu g\ ml^{-1}$). *b*, Crude CSFN, a 1:10 dilution of the sample loaded on the glycerol gradient; the weak upper band corresponds to the 285K band in lane *d*. The much stronger 240K band is largely obscured in the photograph by lower-molecular weight contaminants and/or by proteolytic products, but could be clearly distinguished on the gel. *c–k*, Fractions 6–14 from the glycerol gradient. The sedimentation coefficients, determined by comparison with protein standards[9], are indicated at the bottom for the two peak fractions. *l*, PFN (2.5 $\mu g\ ml^{-1}$, non-reduced); the prominent band is the dimer. *m*, 13S fraction (lane *d*), non-reduced; the protein is entirely oligomeric, entering only 0.5 mm into the 5% gel. *n*, 9S fraction (lane *h*), non-reduced; the protein is a dimer, somewhat larger than PFN. Apparent molecular weights were determined by reference to the upper band of the reduced PFN doublet (lane *a*, assumed MW 220K) and to the PFN dimer (lane *l*, assumed MW 430K). Protein concentrations were estimated by visual comparison of band intensities and by scanning the gels, using PFN (1.25 $\mu g\ ml^{-1}$, lane *a*) as a reference. The concentration of 13S protein (lane *d*) is ~1 $\mu g\ ml^{-1}$, and that of 9S protein ~2–3 $\mu g\ ml^{-1}$ (lanes *g, h*). Quantitation of the crude CSFN was more difficult because of the large background of contaminants, but we estimate that ~20–30% of the 285K and 240K peptides were recovered in the gradient fractions.

The 13S and 9S peak fractions were also electrophoresed in non-reducing conditions to determine the size of disulphide-linked structures (Fig. 1, lanes *m* and *n*). The protein in the 13S fraction barely entered the gel, demonstrating that this material comprises entirely disulphide-bonded oligomers. The 9S fraction showed a single band of apparent molecular weight 450K, demonstrating that the material comprises entirely disulphide-bonded dimers.

Protein concentrations were estimated by visual comparison of band intensities as described in Fig. 1 legend. The final recovery of purified protein was low due to losses in gradient sedimentation and to the low concentration of CSFN peptides in the starting material. Perhaps the most important quantitative aspect is a comparison of the protein recovered in the different gradient fractions. The total protein in the 13S fractions represents about one-quarter of that in the 9S fractions. Thus, the

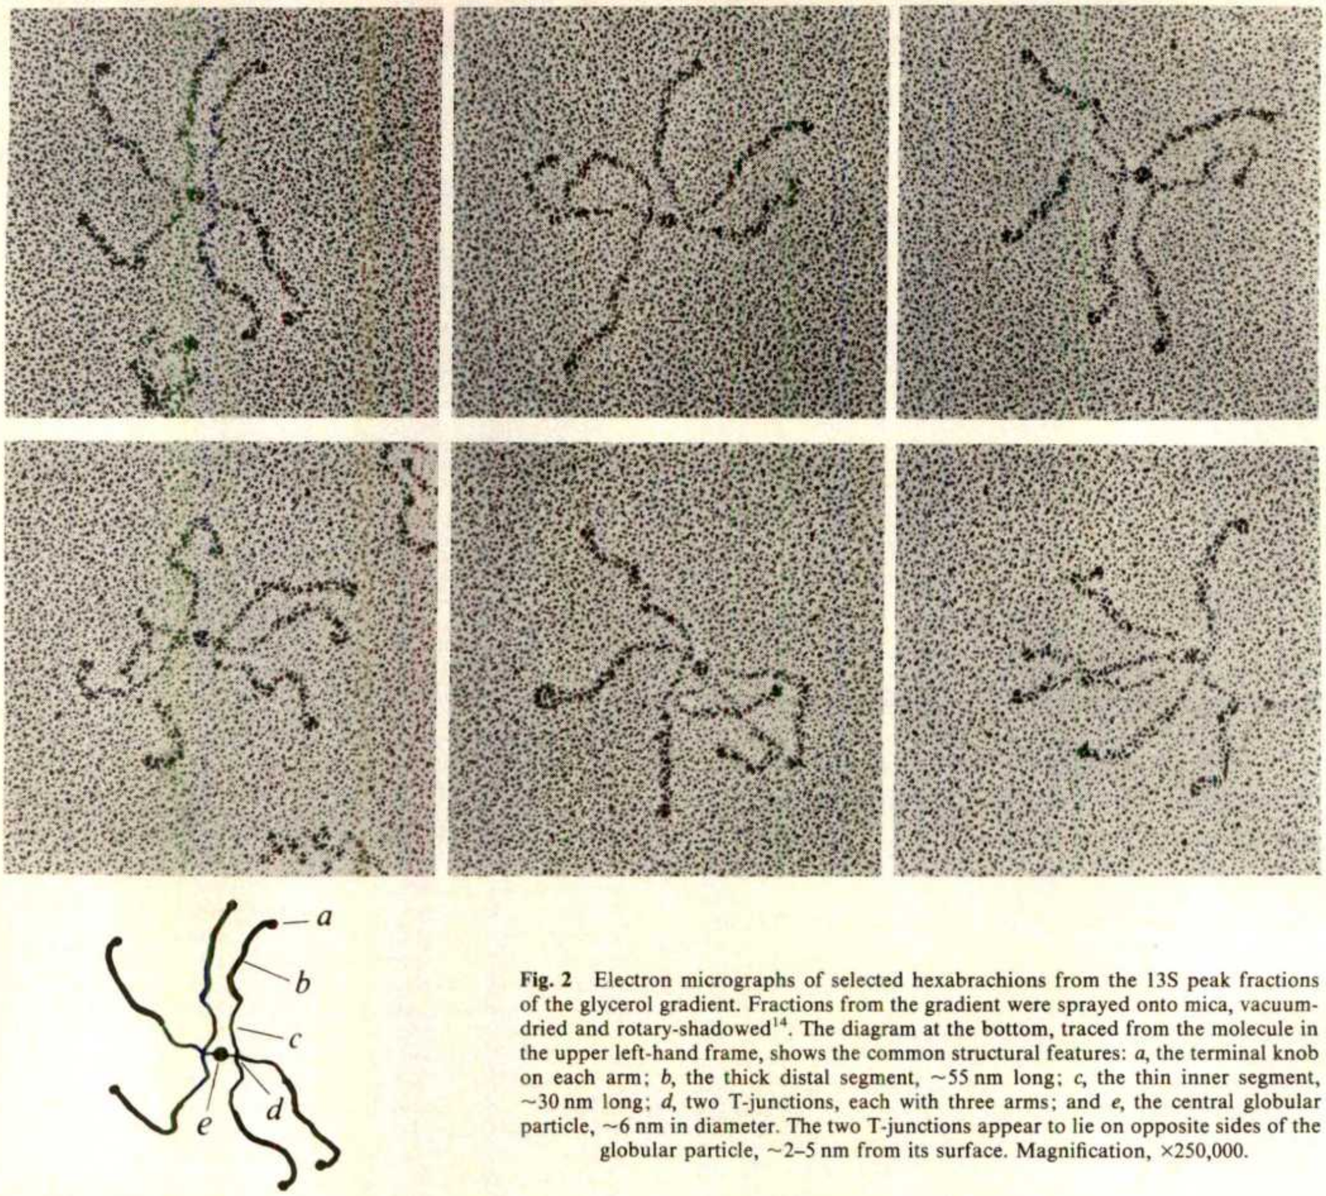

Fig. 2 Electron micrographs of selected hexabrachions from the 13S peak fractions of the glycerol gradient. Fractions from the gradient were sprayed onto mica, vacuum-dried and rotary-shadowed[14]. The diagram at the bottom, traced from the molecule in the upper left-hand frame, shows the common structural features: *a*, the terminal knob on each arm; *b*, the thick distal segment, ~55 nm long; *c*, the thin inner segment, ~30 nm long; *d*, two T-junctions, each with three arms; and *e*, the central globular particle, ~6 nm in diameter. The two T-junctions appear to lie on opposite sides of the globular particle, ~2–5 nm from its surface. Magnification, ×250,000.

oligomers constitute a significant fraction (~20%) of the material recovered after gradient sedimentation.

Electron microscopy of crude CSFN showed a mixture of strands, oligomers of strands, and a variety of globular particles. Oligomers, with the characteristic six-armed structure described below, constituted a significant fraction of the material. Quantitation from the electron microscope specimens was not attempted, but the images were roughly consistent with the 1:4 ratio of protein in the form of oligomers as opposed to dimers estimated above. Specimens prepared after fractionation on the glycerol gradient were much cleaner (no globular particles) and homogeneous. Oligomers were found almost exclusively and in high purity in the 13S fractions. The 9S material consisted largely of single strands, indistinguishable in structure from PFN, with some contamination by fragmented strands.

Electron microscopy showed that the 13S oligomers were not irregular polymers of fibronectin strands. All oligomers had the same structure: six arms emanating from a central globular particle. Figure 2 shows six of the best images obtained; these were selected because the arms were not tangled with each other and could be clearly seen and traced. The same characteristic features were found in over 100 images examined. We found no clear examples with more than six arms. Oligomers with three to five arms, probably the result of proteolysis or incomplete assembly, were found occasionally. As the typical oligomer has six arms we term it a 'hexabrachion'.

The arms are attached to a central globular particle, ~6 nm in diameter (after subtracting for a 1-nm shell of metal). In most images there seem to be two foci or attachment points on opposite sides of the globular core, with three arms extending from each focus; two of the three arms appear to form a continuous strand and the third arm is perpendicular to this strand, forming a 'T' junction. The 'T'-junction appears to lie a few nanometres from the globular particle, suggesting that it is attached to the particle by a short extension.

The arms of the hexabrachions have two structural features that are quite distinct from those of fibronectin dimers. Particularly striking is the small globular domain or knob at the distal tip of each arm. The dimeric molecules, both PFN and the 9S fraction of CSFN, frequently have a kink or forked structure at the ends of the strand[4], but they never show a terminal knob. The second feature peculiar to the hexabrachions is a thickening of the distal two-thirds of the arms. The central 30-nm segment is similar in diameter to the PFN strand but the distal segment, with an average length of 55 nm, appears thicker and more rigid.

The average contour length of the arms was 86.6 nm (s.d. = 5.6 nm, 122 measurements); lengths were measured from the distal knob to the 'T'-junction. When measured from the 'T'-junction, the three arms forming each T-junction were of identical length. The 86.6 nm length is 25% greater than the average length of PFN half-molecules (67–70 nm[4,9]) measured in our laboratory. The additional length of the hexabrachion arms relative to PFN can be accounted for by the higher molecular weight of the polypeptide (285K as opposed to 220K). Some additional protein appears to be needed for the other structural features, especially the central globular particle. The 6 nm diameter particle should contain 50–100K of protein; this might come from the 285K peptides (10K from each arm) or from a separate subunit (which would not have been detected on our lightly loaded gels).

An analysis of CSFN from chicken embryo fibroblasts (supplied by Dr K. Yamada[5], gave a 13S fraction of hexabrachions with essentially the same structural features as those described above. Measurements showed, however, that the arms were substantially shorter (with an average length of 68 nm) than those of the human oligomers. Gel electrophoresis of this material showed bands of 225K (slightly behind the upper band of the human PFN doublet) for both the oligomer and dimer fractions. Thus, the shorter arms of the chicken hexabrachions correspond to their lower subunit molecular weight. It is interesting that in chicken CSFN, which has been studied more extensively than human CSFN, the subunits of the oligomers and dimers have the same apparent molecular weight and are not separated on gels.

Yamada and Kennedy[8] found that CSFN has haemagglutinating activity over 100 times stronger than that of PFN. Our preparation of CSFN had a similarly strong agglutinating activity; when fractions from the glycerol gradient were assayed, the activity was recovered in high yield and exclusively in the 13S oligomer fraction[10]. This fraction agglutinated fixed sheep erythrocytes at a dilution of 1 : 16, that is, at a protein concentration of ~ 50 ng ml^{-1} based on our estimate of 1 μg ml^{-1} for the peak 13S fraction. Thus this activity, ascribed previously to CSFN, is now attributed to the hexabrachions.

Our observations raise the question of whether the hexabrachions, previously considered to be an oligomeric fraction of CSFN, are really fibronectin. Certain features of these oligomers, especially the thin, flexible structure of the arms, are similar to those of PFN and of dimeric CSFN. Other features, such as the terminal knob, central globular particle and the larger subunit size of the human material, strongly suggest that the hexabrachion proteins are distinctly different from fibronectin dimers. We note that several characteristics of the hexabrachions are rather similar to the recently described 'myotendenous antigen', which apparently is different from fibronectin in several other respects[11].

It also seems unlikely that hexabrachions are either precursors or intermediates for fibronectin matrix fibres; they showed no tendency to grow or associate into larger structures, and their architecture, with six arms radiating in all directions, seems poorly adapted to form the parallel array of fine filaments seen in matrix fibres. The elaborate structure of the hexabrachion suggests that it might have some specialized role in cell surface structure or attachment, but its function and its relation to fibronectin remain to be established.

We thank Dr Kenneth Yamada for supplying the preparation of chicken fibroblast fibronectin. The work was supported by NIH grant HL23454.

Lowering of $p\mathrm{H}_i$ inhibits Ca^{2+}-activated K^+ channels in pancreatic B-cells

Daniel L. Cook, Masatoshi Ikeuchi & Wilfred Y. Fujimoto

Departments of Physiology and Biophysics, and of Medicine,
University of Washington, and Veterans Administration Medical
Center, 1660 Columbian Way S., Seattle, Washington 98108, USA

Glucose-dependent periodic electrical activity of membranes of pancreatic islet cells[1,2] mediates calcium uptake[3,4], which is important for glucose-induced insulin release. As yet there has been no direct evidence identifying the 'second messenger' which couples the uptake and metabolism of glucose[4] to the change of membrane electrical activity. Recent evidence showing that intracellular acidification stimulates islet B-cell electrical activity in a glucose-like manner has suggested that protons produced metabolically may serve as messengers by blocking K^+ channels[5] and depolarizing the membrane. Thus protons have been suggested[6] to inhibit the Ca^{2+}-activated K^+-conductance [$G_\mathrm{K}(\mathrm{Ca})$] which is thought[5–9] to produce the 'pacemaker' current responsible for the rhythmic firing of plateau depolarizations[10] and Ca^{2+} spikes[11]. Although these conductance channels have been characterized at the single channel level in several tissues[12–18], little is known of their response to intracellular *p*H (ref. 19) and they have not yet been characterized in B-cells. We have, therefore, used the patch-clamp method to study identified rat B-cells and show here that the B-cell $G_\mathrm{K}(\mathrm{Ca})$ channel is activated by membrane depolarization as well as by cytoplasmic Ca^{2+}, while it is inhibited by acidification of the cytoplasmic membrane surface.

Monolayer cultures of neonatal rat pancreatic islet cells[20] were perfused at room temperature (22–26 °C). Using the giga-seal method of Hamill *et al.*[21], inside-out patches of B-cell membrane (that is, with the cytoplasmic side of the excised membrane exposed to the bath) were voltage-clampled with a Dagan 8900 patch-clamp amplifier. Sampled cells were photographed *in situ* and subsequently identified immunohistochemically[22] as B-cells. In all experiments the pipette and bath contained a control solution consisting of KCl (140 mM), $\mathrm{MgCl_2}$ (2 mM), HEPES (10 mM). KOH was added to adjust the *p*H to 7.2. EGTA (0.1 mM) was added to reduce background free Ca^{2+} in the water to <1 μM before $\mathrm{CaCl_2}$ was added to bring the free Ca^{2+} concentration ($[\mathrm{Ca}]_i$) to the required levels as measured with an Orion calcium-sensitive electrode calibrated by the method of Bers[23]. Calibration buffers containing nitrilotriacetic acid (NTA, 10 mM), KCl (140 mM) and $\mathrm{MgCl_2}$ (2 mM), calculated to have a free [Ca^{2+}] of 14 μM at *p*H 6.8 (0.283 mM $\mathrm{CaCl_2}$ added) and *p*H 7.6 (1.511 mM $\mathrm{CaCl_2}$ added), changed the *p*Ca by <0.01 unit. Test buffers of different *p*H ($p\mathrm{H}_i$) and $[\mathrm{Ca}]_i$ were rapidly changed on the exposed cytoplasmic surface of the membrane patch by passing the electrode tip into streams of test solution flowing from each of five tubes bound together in the bath[24]. The membrane current responses to holding potentials between -80 and $+60$ mV were recorded for 10–15-s intervals on FM magnetic tape and digitized to construct amplitude histograms. Single channel currents were taken as the current step between peaks of the histograms. The areas under each of the peaks of the histogram were used to calculate the percentage of time that 1, 2, 3, …, *n* channels were simultaneously open. The channels in a patch were assumed to be identical and independent, so that the binomial distribution was used to estimate the per cent open time of each single channel[12].

Figure 1*a* shows membrane currents through a patch with three channels held at a membrane potential of -40 mV. When the cytoplasmic side of the membrane was bathed with $[\mathrm{Ca}]_i =$ 10 μM, the membrane current switched rapidly between the

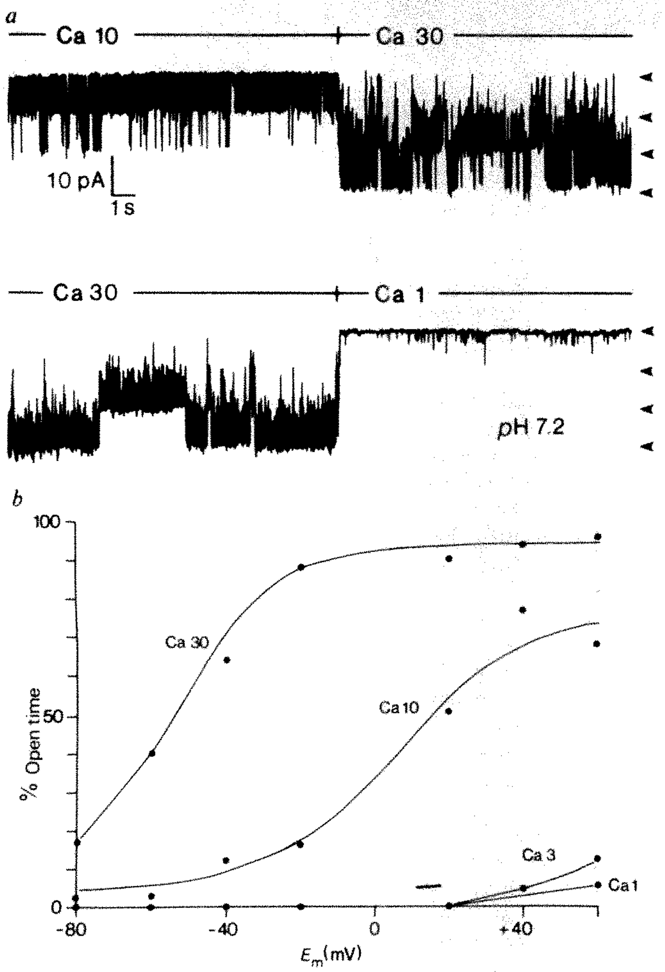

Fig. 1 *a*, Current flow through an inside-out membrane patch from a neonatal rat pancreatic B-cell held −40 mV. The patch was symmetrically bathed in 140 mM KCl solutions with 10 μM free Ca^{2+} ($[Ca]_i$), *p*H 7.2. At the times shown, free $[Ca]_i$ was increased from 10 to 30 μM and then back to 1 μM. Arrowheads mark the current levels corresponding to the leak current (top), and the current flowing with one, two and three channels open. *b*, Plot of the percentage of time that a single channel was open as a function of holding potential for the same patch as in *a* for four levels of $[Ca]_i$ in the range 1–30 μM ($pH_i = 7.2$). The curves are the least-squares fit to the data using equations of the form $y = (a-d)/(1-(x/c)^b)$, where *x* is the free Ca^{2+} level, *c* is the half-maximal activation voltage (corresponding to the E_{50}), *a* and *d* are the activation levels corresponding to 'infinite' hyperpolarization and depolarization, respectively, and *b* is a slope factor which reflects channel sensitivity to membrane potential. As the E_{50} at 10 μM $[Ca]_i$ for these channels was ~+5 mV, they were among the least Ca^{2+}-sensitive of the channels that we have seen.

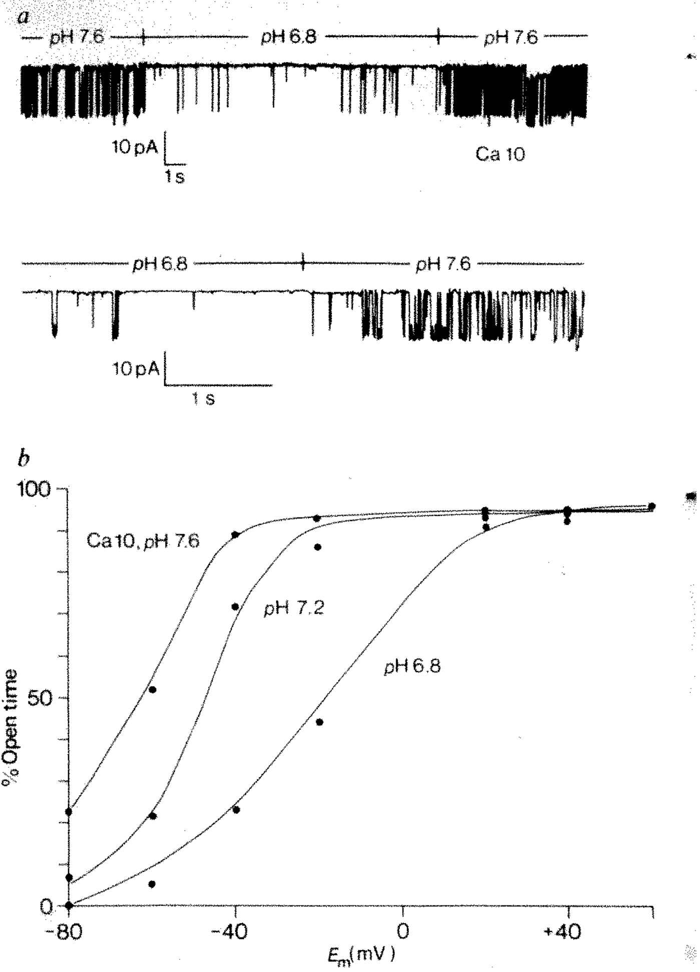

Fig. 2 *a*, Upper trace, current flow through a single channel in another patch held at −60 mV in the presence of 10 μM $[Ca]_i$, *p*H 7.6. Activity was nearly abolished when the *p*H was reduced to 6.8 for 13 s. Lower trace, the transition from *p*H 6.8 to 7.6 shown on an expanded time scale to show details of channel events. *b*, Plot of percentage open time against holding potential for the patch shown in *a*, bathed with $[Ca^{2+}]$ 10 μM (Ca 10) at *p*H 6.8, 7.2 and 7.6. The E_{50} for 10 μM $[Ca]_i$, *p*H 7.2 was ~−49 mV, indicating that this channel was among the most Ca^{2+}-sensitive channels that we have seen.

all-closed state (the top arrow) and two states in which one or two channels were open (the second and third arrows). $[Ca]_i$ was abruptly increased to 30 μM and within 200 ms activity of the channel increased so that two or three channels were open most frequently (the third and fourth arrows). After a further 80 s, reducing the $[Ca]_i$ to 1 μM closed all channels.

Changes in membrane potential produced two effects. First, single channel currents varied with membrane potential in a nearly linear manner with equilibrium potentials near zero and single channel conductances which averaged 244±4 pS ($\bar{x}$ ± s.e.m., *n* = 9). There was no effect of $[Ca]_i$ on channel conductance. Second, membrane depolarization activated the channels (recordings not shown) so that the per cent open time increased in a sigmoid manner (Fig. 1*b*) for constant $[Ca]_i$. As $[Ca]_i$ was increased from 1–30 μM, there was a progressive shift to the left of these activation curves so that at $[Ca]_i = 10$ μM channels are active in the physiological voltage range.

Figure 2*a* shows records from another patch exposed to 10 μM $[Ca]_i$ while pH_i was transiently lowered from 7.6 to 6.8 (upper trace) which blocked channel activity substantially and reversibly. The transition from *p*H 6.8 to 7.6 has been expanded on the time scale to show more detail of the channel activity in the lower trace. As with changes of $[Ca]_i$, pH_i changes had no effect on channel conductance. Acidification of the cytoplasmic side of the membrane shifted the activation curves to the right, away from the physiological voltage range (Fig. 2*b*), while increase in alkalinity shifted the curves to the left.

As a simple method to compare the voltage dependence of channel activation between experiments, we determined the membrane potential required for half-maximal channel activation (E_{50}) from curves fitted to the data as described in Fig. 1 legend. The E_{50} in the presence of 10 μM $[Ca]_i$ varied considerably from patch to patch (from −55 mV to +12 mV, *n* = 9; see also refs 13, 14). For a given patch, the channel sensitivity to changes of $[Ca]_i$ could be assessed by plotting the E_{50} for each Ca_i against log $[Ca]_i$. The slopes of these curves (measures of channel sensitivity to $[Ca]_i$ were highly variable (−84±8, $\bar{x}$ ± s.e.m., range −38 to −115 mV per decade increase of $[Ca]_i$, *n* = 9). The channels had a comparable sensitivity to changes in proton concentration as the slopes of the E_{50} versus pH_i curves had the same range (−61±10, range −31 to −100 mV per *p*H unit, *n* = 5) and were not significantly different from the channel sensitivity to $[Ca]_i$ in the five patches where both were determined. Thus, a 10-fold increase of proton concentration (that is, −1 pH.unit) would be expected to counteract a 10-fold increase of $[Ca]_i$.

This report is the first direct characterization of G_K(Ca) channels in pancreatic B-cells where they are thought to regulate membrane electrical activity and Ca^{2+} uptake[7–9]. The unit conductance and the sensitivities to membrane voltage and to $[Ca]_i$ appear to be comparable with the G_K(Ca) channels described in other systems[12–16] but may be less sensitive to Ca^{2+} than the G_K(Ca) channels in salivary gland[15] and pancreatic acinar cells[18]. This is also the first demonstration that acidification of the cytoplasmic membrane surface can inhibit G_K(Ca) channel activation[19]. This may have important implications; for example, cytoplasmic acidification accompanies Ca^{2+} uptake during the spiking phase of electrical activity in molluscan bursting neurones[25]. If molluscan G_K(Ca) channels, which may be electrical pacemakers in these cells[26], are also pH-sensitive, then their electrical rhythm may depend not only on Ca^{2+} fluxes and buffering, but also on intracellular H^+ buffering and the apparent competition between Ca^{2+} and H^+ for binding sites[27]. Similarly, Ca^{2+}–H^+ interactions at the B-cell membrane may be important determinants of B-cell G_K(Ca) activation and electrical activity.

This observation also provides direct evidence for a possible link between the metabolism of glucose[4] and the changes of electrical activity[1,2] and cation fluxes[3,4] which trigger insulin release. It has been suggested[5,6] that protons produced during glycolysis, which increase with glucose stimulation[28], acidify the cell membrane, block a background K^+ conductance and stimulate electrical activity by depolarizing the membrane. Our observations (Fig. 2*a*, *b*), while consistent with this idea, suggest that protons may do more than simply block a background depolarizing current. Thus, G_K(Ca) channels are thought[7–9] to conduct the dynamic pacemaker current which alternately turns on and off the slow, voltage-dependent plateau current[10] which triggers Ca^{2+} spiking. Proton-mediated inhibition of this pacemaker current may thus explain how glucose prolongs the spiking plateau phase and shortens the silent phase[1,2,6].

Intracellular ATP directly blocks K^+ channels in pancreatic B-cells

Daniel L. Cook & C. Nicholas Hales

It is known that glucose-induced depolarization[1–4] of pancreatic B-cells is due to reduced membrane K^+-permeability[5–8] and is coupled to an increase in the rate of glycolysis[9], but there has been no direct evidence linking specific metabolic processes or products to the closing of membrane K^+ channels. During patch-clamp studies of proton inhibition of Ca^{2+}-activated K^+ channels [G_K(Ca)] in B-cells[10], we identified a second K^+-selective channel which is rapidly and reversibly inhibited by ATP applied to the cytoplasmic surface of the membrane. This channel is spontaneously active in excised patches and frequently coexists with G_K(Ca) channels yet is insensitive to membrane potential and to intracellular free Ca^{2+} and *p*H. Blocking of the channel is ATP-specific and appears not to require metabolism of the ATP. This ATP-sensitive K^+ channel [G_K(ATP)] may be a link between metabolism and membrane K^+-permeability in pancreatic B-cells.

Figure 1 shows that when ATP (1 mM) is applied to the patches it immediately, completely and reversibly blocks channel activity for the duration of ATP exposure, which in other experiments lasted for several minutes. ATP in the bath was acting on the inner membrane surface as G_K(Ca) channels, when they occurred in the same patch, were activated[10] by membrane depolarization and by increases in bath Ca^{2+} concentration, as expected of an inside-out patch. Bath Ca^{2+} concentration ((10^{-9}–3×10^{-5} M), bath pH (6.8–7.6) and membrane potential had no effect on G_K(ATP) channel activation. Single unit current–voltage curves were nearly linear (Fig. 2) with an average channel conductance at negative voltages of 53.9 ± 1.7 pS ($\bar{x} \pm$ s.e.m., $n = 9$). Increasing the bath concentration of KCl to 210 mM shifted the equilibrium potential to the left (Fig. 2*a*), as expected of a channel which is K^+-, rather than Cl^--permeable. Adding 70 mM NaCl to the bath reduced the K^+ current (Fig. 2*b*) without shifting the equilibrium potential, suggesting that

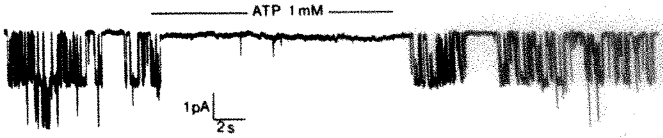

Fig. 1 Effect of 1 mM ATP on K^+-selective ion channel currents in an inside-out patch of membrane excised from a pancreatic B-cell cultured from neonatal rat. The membrane potential was −40 mV. Downward deflections correspond to currents flowing through the membrane patch as if flowing into the cell. Monolayer cultures of neonatal rat islet cells[20] were perfused at room temperature (20–22 °C) in a 0.5-ml chamber. Membrane patches of cells, identified as B-cells using immunohistochemical methods[21,22], were excised (inside-out patches) using the giga-seal method of Hamill *et al*[23]. Patches were perfused on their exposed cytoplasmic surfaces with ionic buffers containing: 140 mM KCl, 2 mM $MgCl_2$, 10 mM HEPES, 0.1 mM EGTA. $CaCl_2$ was added to adjust free Ca^{2+} to 3 μM as measured with an Orion Ca^{2+}-sensitive electrode. Low ((10^{-9} M) Ca^{2+} buffers contained 10 mM EGTA with no added $CaCl_2$. KOH was added to adjust the pH to 7.2. Recording pipettes were filled with this buffer while buffers containing various test substances flowed through each of five tubes (0.2 mm internal diameter) suspended next to each other in the chamber. The solution to which the patch was exposed was changed by moving the electrode tip into the effluent stream at the mouth of each tube[24]. Membrane currents were recorded with a Dagan 8900 patch-clamp amplifier onto FM magnetic tape for computer analysis.

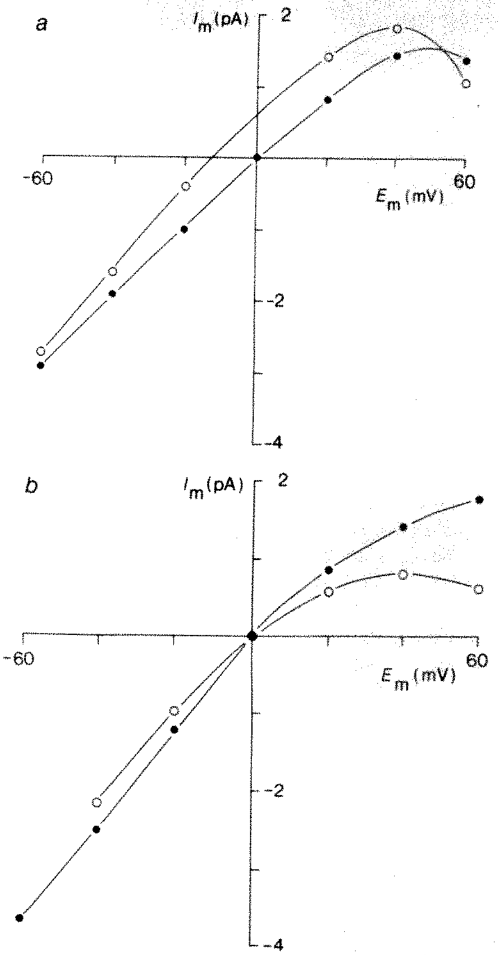

Fig. 2 Current–voltage (I/V) relationships for ATP-sensitive K$^+$ channels. *a*, In symmetrical conditions (140 mM KCl on both sides) the I/V was linear in the negative membrane potential range but showed rectification with deporlarization beyond zero. Increasing the bath KCl concentration from 140 mM (control, ●) to 210 mM (○) shifted the I/V curve to the left, indicating that K$^+$, rather than Cl$^-$, is the permeant ion. The expected equilibrium potential shift was −10.2 mV. The unitary conductances were 48 pS and 59 pS with 140 mM and 210 mM bath KCl, respectively. *b*, Adding 70 mM NaCl to the bath reduced the channel currents, in another patch, without shifting the curve, suggesting that Na$^+$ can block but not permeate the channel. The unitary conductances were 62 pS and 53 pS with control (●) and 70 mM NaCl (○), respectively.

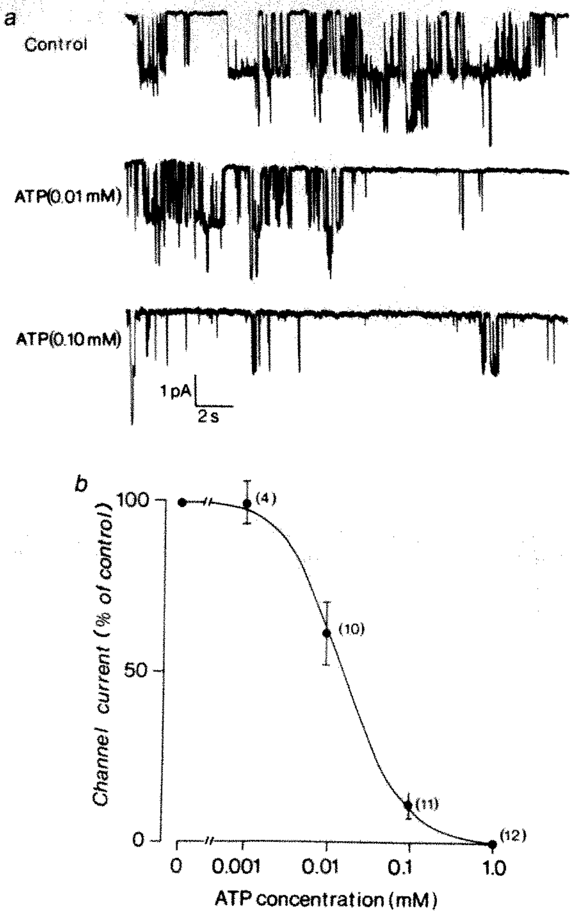

Fig. 3 Dose-dependent effects of ATP on channel activity. *a*, Channel current recordings of a B-cell membrane patch held at −40 mV while exposed to zero (top), 0.01 mM (middle) and 0.10 mM (bottom) ATP. The channels had a decreasing probability of being open and a reduction of average channel current as the ATP concentration was increased. *b*, Average channel currents, expressed as a percentage of the control (no ATP) current ($\bar{x} \pm$ s.e.m.) for 12 patches at four ATP concentrations. The curve is a least-squares fit of the data to the equation $y = 100 - 100/(1+(x/c)^b)$, where $c = 0.015$ (the half-maximal inhibitory concentration of ATP) and $b = 1.18$ (the Hill coefficient).

intracellular Na$^+$ may block but not traverse the channel. The K$^+$ channel blockers, 9-aminoacridine (9-AA 100 μM) and 4-aminopyridine (4-AP, 10 mM), each nearly abolished channel activity. Tetraethylammonium (TEA, 10 mM) and quinine (100 μM) reduced channel conductances by ~30% and 10%, respectively, while reducing channel activity by 80–90%.

Submaximal doses of ATP had graded effects on channel activity (Fig. 3*a*) such that 0.01 mM ATP suppressed activity by ~50% while 0.10 mM ATP nearly abolished activity. To account for time-related variations of activity (for example, middle trace of Fig. 3*a*) the ATP dose–response curve of Fig. 3*b* was constructed by integrating total channel currents for 20–60 s at each of several ATP doses in 12 patches. The half-maximal inhibitory dose of ATP was 0.015 mM. Suppression of channel activity appeared to be specific for ATP as 1 mM each of AMP, GTP or UTP had no effect on channel activity while 1 mM ADP was generally less effective than 0.01 mM ATP. Furthermore, channel suppression appeared not to require metabolism of ATP as Mg^{2+}-free, 1 mM ATP and the ATP analogue, adenylylimidodiphosphate (AMP–PNP, 1 mM), were each as effective and as rapidly active as 1 mM ATP.

These results show that pancreatic islet B-cells possess a K$^+$-selective channel which is rapidly and reversibly blocked by cytoplasmic ATP. The relative potency of adenosine nucleotides (ATP > ADP, with no effect of AMP) differs quantitatively from that described for purinergic receptors[11] but matches the potencies for an ATP-sensitive K$^+$ channel recently described in cardiac tissue[12]. The unit conductance of the B-cell channel, however, was lower (54 compared with 65 pS) while the half-maximal inhibitory concentration of ATP (K_i) was considerably lower (0.015 compared with 0.100 mM). Whether these differences are due to differences of species, tissue or experimental conditions is unclear.

The G_K(ATP) channel may provide a significant component of B-cell K$^+$-permeability as it is observed more commonly than G_K(Ca) channels, and it may explain several findings in B-cells. First, the hyperpolarization by metabolic poisons, ascribed to the intracellular dumping of bound Ca^{2+} and activation of G_K(Ca) channels[13], may also be due to a fall in ATP levels and activation of G_K(ATP) channels. Second, the depolarization and decrease of ^{86}Rb$^+$ efflux seen with TEA[4,14], 9-AA[15] and quinine[13,16] may be partially due to a block of G_K(ATP) channels. Third, the decrease of input impedance and hyperpolarization seen during whole-cell, giga-seal recordings[17] was attributed to an increase in K$^+$-conductance following the loss of a cytoplasmic factor into the recording electrode; our results suggest that ATP may be that factor.

The physiological role of these channels in the B-cell is unclear. Noma[12] has suggested that G_K(ATP) channels may hyperpolarize and inactivate cardiac cells to maintain ATP levels during ischaemia. Although this may occur in B-cells, and perhaps other excitable cells, the extreme channel sensitivity to ATP is puzzling as B-cell electrical and secretory activity cease during glucose withdrawal which lowers islet ATP content by only 20–45% (refs 18, 19). We have two suggestions to explain this: (1) our estimate of the K_i for ATP in these experimental conditions may be artificially low, and (2), cytoplasmic free ATP levels in cells may be lower than generally thought (that is 1–3 mM) since ATP measurements do not account for possible ATP binding or partitioning into organelles. It may be that, given proper ionic gradients, temperature, and intra- and extracellular factors, the K_i for ATP more closely matches free ATP levels in ischaemia. More importantly, the K_i may even approximate physiological ATP levels so that changes of ATP level, or changes of other factors, may modulate G_K(ATP) channels and membrane potential at physiological glucose levels.

We thank Drs E. G. Krebs and D. Porte Jr for their support and encouragement in this project; and Jean Liang for technical assistance. The product of *ras* is a GTPase and the T24 oncogenic mutant is deficient in this activity

Raymond W. Sweet*, Shiro Yokoyama*, Tohru Kamata†, James R. Feramisco†, Martin Rosenberg* & Mitchell Gross*

Ha-*ras* is a member of a multigene family in man which encode highly related proteins of 189 amino acids (p21)[1–6]. *In vitro*, *ras* proteins bind GTP[7–9], and p21 mutants with threonine at position 59 autophosphorylate at that residue[10–12]. Mutation (at amino acids 12 or 61)[6,13–16] and elevated expression[17] of *ras* genes result in cell transformation in culture, and are also observed in many types of human tumours[18]. Normal and mutant transforming *ras* proteins show no differences in localization, lipidation or GTP binding[9]. However, mutations at position 12 in recombinant (Thr 59) p21 molecules were observed to affect autophosphorylation[12]. We have expressed the full-length normal and T24 transforming (Gly → Val at position 12) Ha-*ras* proteins in Escherichia coli and have purified them to homogeneity (ref. 19 and M.G. *et al.*, in preparation); these proteins bound GTP with approximately molar stoichiometry and with an affinity comparable to partially purified mammalian proteins. Microinjection of the T24 protein into quiescent rodent fibroblasts resulted in a rapid alteration in cell morphology, stimulation of DNA synthesis and cell division[19]; in contrast, little response was observed with the normal protein. We now report that the normal *ras* protein has an intrinsic GTPase activity, yielding GDP and P_i. In contrast, the T24 transforming protein is reduced 10-fold in this activity. We suggest that this deficiency in GTPase is the probable cause for the transforming phenotype of the T24 protein.

Measurement of the GTP-binding properties of *ras* proteins has relied on immunoassays necessitated by the low levels of p21 in normal or transformed mammalian cells[7–9]. Having quantities of essentially pure normal and T24 p21 produced in *E. coli* has allowed us to assess more accurately their GTP binding by standard filter-binding assays (M.G. *et al.*, in preparation). Figure 1*a* shows the kinetics of binding for reactions containing 25 nM [α-^{32}P]GTP and an excess (~300 nM) of either the normal or T24 protein. As measured by retention of ^{32}P on filtration through nitrocellulose, a maximal binding of 15–18 nM was obtained with both proteins within 20 min; no binding was observed in the control reaction containing only bovine serum albumin (BSA). However, the initial rate of binding with the T24 protein was 2–3-fold slower than with the normal protein. This differential rate is reproducible at saturating GTP concentrations and probably reflects a perturbation of the GTP-binding site by the substitution of valine for glycine at position 12. The apparent maximal binding of 70% is characteristic of the filter assay. By a second assay (gel filtration through Sephadex G-25) about 95% binding was observed at the 30-min time point.

The conditions for the rapid complete binding of GTP shown in Fig. 1*a* were specifically chosen to assay our p21 proteins for GTPase activity. To measure hydrolysis of the bound [α-^{32}P]GTP, samples of the reactions described above were analysed by TLC on PEI cellulose (Fig. 1*b*). The normal protein did hydrolyse GTP to GDP with an estimated $t_{1/2}$ of ~2 h (reaction 1). In contrast, a much slower rate of hydrolysis was seen with the T24 transforming protein (reaction 2). No hydrolysis occurred in the control with BSA alone (reaction 3). Most of the GDP product remains associated with p21 as evidenced by the relatively constant level of binding throughout the time course of the assay (Fig. 1). However, the GDP is not covalently bound as it is released on denaturation of the protein (see Fig. 1 legend).

To monitor the fate of the hydrolysed γ-phosphate group of GTP, similar reactions were performed with [γ-^{32}P]GTP. As shown in Fig. 2, the initial binding kinetics were comparable to those observed in Fig. 1 with the α-labelled GTP. However, the amount of ^{32}P associated with the normal protein decayed markedly with time, indicating that the γ-phosphate group was hydrolysed and released from the p21–nucleotide complex. This conclusion was verified by TLC analysis which showed a corresponding increase in free ^{32}P-orthophosphate (Fig. 2). From these results, we estimate that the hydrolytic rate for the GTPase activity of the normal protein is $4\times10^{-5}\ \mathrm{s}^{-1}$. By a comparable

Table 1 Immunoprecipitation of GTPase activity

Reaction no.	Sample	Time (h)	Binding (% unbound)	Hydrolysis (%) GTP	GDP	GMP
(1)	p21 + antibody					
	bound	0.5	—	89	11	0
		1.0	—	81	19	0
	sup	0.4	93	94	5	1
		1.2	81	89	9	2
(2)	Antibody − sup	1.2	100	94	5	1
(3)	p21 − sup	1.2	100	96	3	1
	[α-^{32}P]GTP mix			97	2	1

Purified Ha-*ras* protein (0.8 μg) was incubated with 60 μg of ammonium sulphate fractionated monoclonal antibody 259 (ref. 20) in 100 μl of GTP buffer containing 0.1% Triton X-100, 50 μM phenylmethylsulphonyl fluoride and 0.3 mg ml^{-1} BSA at 0 °C for 60 min. Then 20 μl of protein A–Sepharose beads (Pharmacia), coated with rabbit anti-rat IgG (Cappel) and equilibrated in GTP buffer/0.1% Triton, was added and the sample was mixed for 25 min at 4 °C (sample 1). Similarly, IgC-coated beads were incubated with either 180 μg of monoclonal antibody 259 (sample 2) or 0.8 μg of p21 (sample 3) alone. The beads were washed extensively with GTP buffer containing 0.12 M $(NH_4)_2SO_4$ and 0.1 mg ml^{-1} BSA. The beads were then resuspended in 120 μl of this latter buffer containing 25 nM [α-^{32}P]rGTP and incubated at 25° with occasional mixing. At the indicated times, the beads were pelleted and duplicate aliquots (5 μl) of the supernatant (sup) were counted. The binding results are presented as per cent of ^{32}P remaining in these aliquots relative to the initial concentration. To monitor for hydrolysis of unbound GTP, a third 5-μl aliquot at each time was treated for TLC as described in Fig. 1 legend. Hydrolysis of bound GTP was measured by removing samples of the beads, washing in GTP buffer/0.01% Triton and elution at 65 °C with EDTA/SDS TLC sample buffer. No radioactivity was bound to the beads in reactions 2 and 3 (<0.5% of reaction 1). TLC analysis was as described in Fig. 1 legend and the per cent of ^{32}P as GTP, GDP and GMP was quantitated as in Fig. 2. The extent of hydrolysis in reaction 2 overestimates the contribution of phosphatases contaminating the monoclonal antibody in reaction 1 because the beads were treated with three times as much antibody.

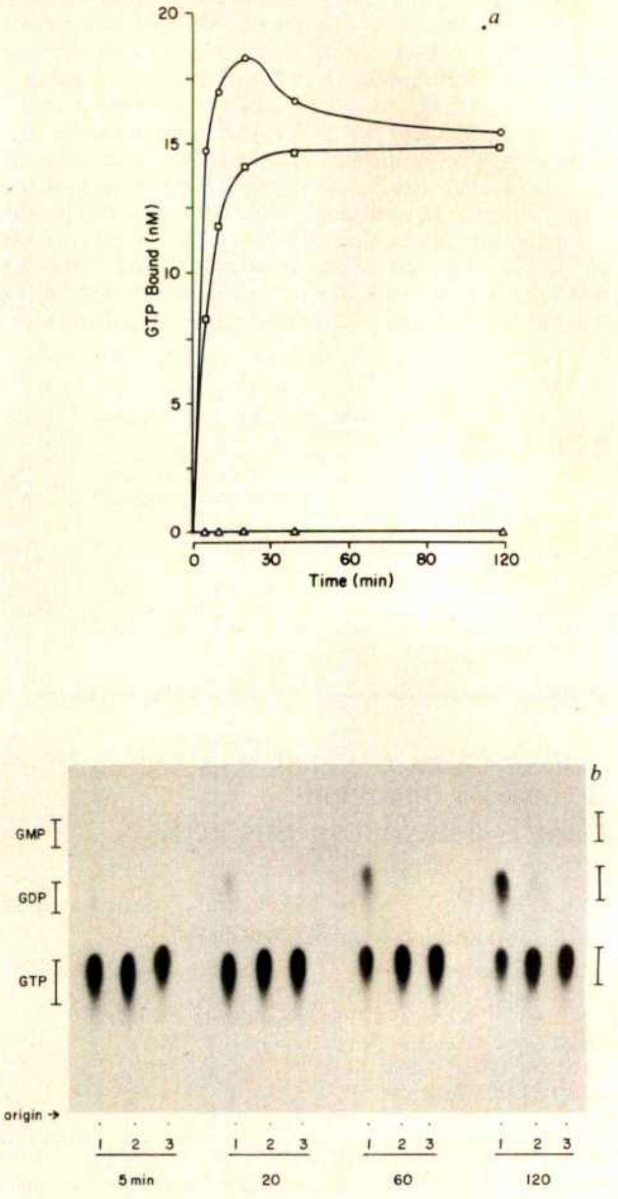

Fig. 1 Binding and hydrolysis of [α-^{32}P]rGTP. *a*, Filter binding of [α-^{32}P]GTP to 0.3 μM normal protein (○, reaction 1), 0.3 μM T24 protein (□, reaction 2) and control (△, no addition). *b*, Thin layer chromatography of samples from reactions 1, 2 and 3 at various times. 1, Normal protein; 2, T24 protein; 3, no addition. **Methods:** *a*, Filter binding reactions were carried out with 25 nM [α-^{32}P]rGTP (15 TBeq mmol^{-1}; Amersham) in 0.25 ml GTP/AS buffer (10 mM Tris-HCl-*p*H 7.5, 100 mM NaCl, 5 mM $MgCl_2$, 0.12 M $(NH_4)_2SO_4$, 0.2 mg ml^{-1} BSA) at 25 °C. At the indicated times, duplicate 20-μl samples were added to 2 ml of cold GTP buffer (Tris-HCl, NaCl, $MgCl_2$ as above) plus 10 μg ml^{-1} BSA. The samples were filtered through nitrocellulose (0.45 μM, Schleicher & Schnell), rinsed with 20 ml of cold GTP buffer and counted. Protein determinations were made with the Bio-Rad Coomassie blue–phosphoric acid reagent with bovine γ-globulin as the standard[30]. Molecular concentrations of *ras* proteins were estimated assuming a molecular weight of 21,000. *b*, At the indicated times, samples (5 μl) of the above reactions were added to an equal volume of 2 mM EDTA/0.5% SDS containing 8 mM each of GTP, GDP and GMP; 2 μl of each sample were spotted onto a prewashed PEI–cellulose plate with fluorescent indicator (Baker) and developed with 1.6 M LiCl. The carrier nucleotide spots were observed by UV illumination and the chromatogram was exposed to X-ray film (Kodak, XAR-5) for 5 h at room temperature.

analysis, the GTPase activity of the T24 protein was 10-fold lower than that of the normal protein (Fig. 2). This quantitation agrees with the autoradiographic results shown in Fig. 1*b*. Thus, we conclude that the normal *ras* protein is a GTPase and that this activity is markedly reduced in the T24 mutant.

It is important to demonstrate that this GTPase activity is intrinsic to p21 rather than arising from a contaminating *E. coli* protein. We can make two strong arguments against a contaminating GTPase. First, the normal and T24 proteins differ 10-fold in GTPase activity, yet both are expressed in the same host/vector system and both purify in a similar manner through identical protocols. In addition, in one preparation of the normal protein, we measured the GTPase activity across the single GTP-binding peak in the final purification step (DEAE–Sephacel column chromatography). The hydrolytic activity co-migrated with binding and the ratio of these two activities was constant throughout the peak (unpublished observations).

Second, and more directly, the GTPase activity of the normal protein was immunoprecipitable by a monoclonal antibody[20] directed against the Harvey virus p21 protein obtained from mammalian cells (Table 1). In this assay, the normal protein was first incubated with the rat monoclonal antibody and then linked to protein A–Sepharose beads coated with an anti-rat IgG antibody. The beads were incubated with [γ-^{32}P]GTP and binding was monitored by measuring the decline of free GTP in the supernatant. As shown in Table 1, ~20% of the GTP was associated with the beads after 70 min (reaction 1). In comparison, no binding occurred in control reactions containing anti-rat antibody-coated beads which had been pretreated with either monoclonal antibody (reaction 2) or the normal p21 (reaction 3) alone. To assess the GTPase activity of the

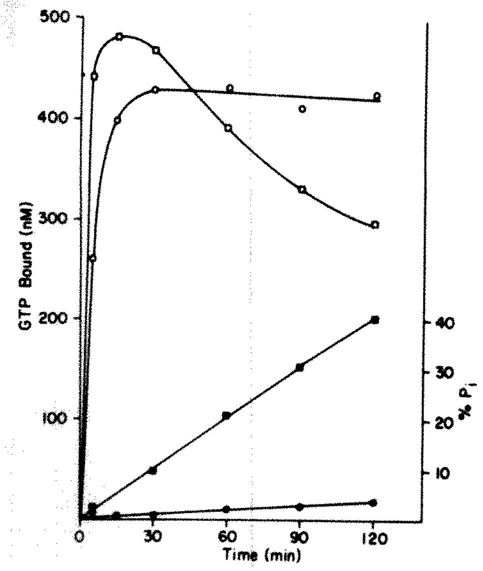

Fig. 2 Binding and hydrolysis of [γ-^{32}P]rGTP. Filter binding for the normal (□) and T24 (○) proteins. % P_i by TLC for the normal (■) and T24 proteins (●).

Methods: The reactions, binding and TLC analysis were as described in Fig. 1 legend except that the labelled nucleotide was [γ-^{32}P]GTP (0.7 μM, 630 MBeq mmol^{-1}; Amersham) Radioactivity on the TLC plate was visualized by exposure to X-ray film (not shown), and the P_i and GTP spots (the only products) were excised and measured in a scintillation counter. As in Fig. 1*b*, no binding or hydrolysis was observed in the control reaction without *ras* protein (not shown).

Sepharose-bound *ras* protein, samples of the beads in reaction 1 were washed extensively, treated with 0.25% SDS to dissociate the bound protein and ^{32}P-labelled nucleotide, then analysed by TLC. The results (Table 1, reaction 1, bound) show that hydrolysis to GDP occurred in a time-dependent manner such that about 20% of the bound nucleotide at 1 h was GDP. This hydrolysis did not result from phospholytic enzymes present in the antibody preparations. In the supernatants of the control reactions containing beads treated with either monoclonal antibody or normal *ras* protein alone (reactions 2 and 3 respectively), <3% conversion to GDP was observed in 70 min. The significant fraction of GDP in the supernatant of reaction 1 must result either from turnover of the hydrolysed GDP on the beads or from release of the nucleotide–p21 complex from the beads during the incubation. In summary, the co-purification of the GTPase and GTP-binding activities and the immunoprecipitation of the GTPase by anti-*ras* monoclonal antibody establish that the GTPase is an intrinsic activity of *ras*.

The GTP-binding and hydrolytic activities of our bacterially produced *ras* proteins occur at very slow rates compared with what might be expected physiologically. Post-translational modifications (for example, lipidation[21]) of the *ras* proteins in mammalian cells may partially account for this discrepancy. However, immunoprecipitated complexes of p21 from mammalian cells show binding kinetics similar to those presented in Table 1 for the bacterially-produced protein (unpublished results). Furthermore, if autophosphorylation is indicative of a GTPase activity (see below), the mammalian proteins have an equally slow hydrolytic activity[10,12]. This situation may be similar to that described for the G_α subunits of the regulatory proteins of adenylate cyclase[22] and for the T_α subunit of transducin[23]. In purified form, these proteins alone or in combination with their partner $\beta\gamma$-subunits exhibit GTP hydrolytic rates similar to that observed with our normal Ha-*ras* protein prepared in *E. coli*[24–27]. However, reconstitution of the G proteins or transducin into lipid vesicles containing appropriate membrane components stimulates their GTPase activity by orders of magnitude[25–27]. As *ras* proteins are membrane-associated[8,28], their reconstitution into membrane complexes may similarly stimulate their binding and hydrolytic activities.

The 10-fold reduction in GTPase activity of the T24 protein represents the first major biochemical differentiation between the products of a normal and a transforming mutant *ras* gene. It is tempting to speculate on the consequence of this altered activity by drawing a functional analogy to transducin and the G stimulatory protein—both of these proteins are activators of enzymes affecting cyclic nucleotide pools[22,23]. This activation requires GTP binding (or exchange of GTP for bound GDP) and appears to terminate on hydrolysis to GDP[23,29]. If the *ras* proteins have an analogous regulatory function in whichever proliferative control pathway they participate, then the deficiency in GTPase activity of the T24 mutant could result in prolonged stimulation of an otherwise regulatable activity. As shown for the G stimulatory protein[22], perhaps modulation of *ras* activity itself occurs through interactions with other proteins, and these interactions may be sensitive to whether GTP and GDP (or neither) occupies the nucleotide binding site.

The autophosphorylating activity of *ras* proteins having threonine at position 59 is probably a consequence of the GTPase activity described here[12]. In a recent characterization of this autophosphorylating activity, Gibbs *et al.*[12] compared the effects of substitutions at position 12 in recombinant (Thr 59) p21 proteins. Interestingly, replacement of glycine with valine increased the rate of autophosphorylation, the opposite of the effect on GTPase activity described here. Thus, we surmise that hydrolysis and autophosphorylation compete for bound GTP and the slower rate of hydrolysis increases the probability of intramolecular phosphorylation.

We thank M. Wigler and J. Stadel for helpful discussions, M. Furth for providing the Y13-259 hybridoma cell line and 0. Finney for typing the manuscript. This work was supported in part by NIH grants GM28277 and CA13106.

Note added in proof: By procedures described in Table 1, we have examined the GTPase activities of the human H-*ras* and T24 gene products synthesized in mammalian cells. The activity of the H-*ras* protein is at least 5-fold greater than that of the T24 mutant and is comparable to the activity of the H-*ras* protein produced in bacteria (S. Yokoyama *et al.*, unpublished results).

A common function for polyoma virus large-T and papillomavirus E1 proteins?

Philippe Clertant* & Isabelle Seif†

91190 Gif-sur-Yvette, France

Nucleotide sequencing has revealed a common genetic organization for three papillomaviruses: BPV-1 (bovine papillomavirus type 1), HPV-1 (human papillomavirus type 1a) and HPV-6 (human papillomavirus type 6b)[1–4]. Several open reading frames, corresponding to as yet uncharacterized proteins, were observed in these genomes in the region that is required for oncogenic transformation by BPV-1 and for plasmidial maintenance of its genome[5]. The longest of these frames, E1, is also the most conserved between the three viruses[3,4]; we have compared the amino acid sequence of its putative product ('E1 protein') with those of the large-T proteins of three polyoma viruses[6–11] and report here significant homologies in their carboxy-terminal halves, extending for over 200 amino acids. Moreover, similar secondary structures were predicted[12,13] in this region, especially in two blocks of homologous residues, which correspond in the large-T proteins of polyoma and simian virus 40 (SV40) viruses to sites involved in the ATPase[14,15] and nucleotide-binding activities[16]. These observations suggest that the papillomavirus E1 proteins might have a function in common with the polyoma virus large-T proteins (which are required for the initiation of viral DNA replication[17]). As it was suggested recently that the E1 gene product is involved in maintaining the BPV-1 genome as a plasmid in transformed cells[18,19], we speculate that the structural features conserved in these otherwise very different viruses are general characteristics of eukaryotic proteins involved in the control of DNA replication.

Similarities between the amino acid sequences of the large-T proteins of SV40 and polyoma[10] or BK[8] viruses have been reported previously. Subsequently, it became possible to compare these sequences with those encoded by the genomes of the papillomaviruses BPV-1 (ref. 1), HPV-1 (ref. 2) and HPV-6 (ref. 3). The overall genetic organization of the papovaviruses and papillomaviruses is very different[4]. We observed, however, significant similarities between part of the large-T proteins and the carboxy-terminal half of the proteins encoded in the largest open reading frame of the three papillomaviruses, designated E1. These homologous regions were detected by comparing the two alignments made within each group (polyoma virus large-T proteins[8,10] and papillomavirus E1 gene products[3]). Starting from the most conserved regions within each class of proteins, we first looked for the best adjustment of either identical or functionally analogous amino acids, and found clusters of homologous or similar residues spanning the entire carboxy-terminal half of the E1 sequences (Figs 1, 2). This region represents the most conserved part of the E1 sequence between the three papillomaviruses[3]. Figure 2 shows the amino acid sequences in this conserved region: two blocks of homology (B and C) are surrounded by two additional zones where the analogy may be extended (A and D). The blocks of homology are in the same relative order in proteins of the two groups.

The validity of this result was confirmed by computer comparison of the proteins, using an alignment program[20] (provided by Dr J. M. Claverie). Pairwise comparisons were made, either for blocks of 100 amino acids centred on the analogous clusters (indicated by A–D in Figs 1, 2), or for larger segments (Table 1). For regions B and C, taken either separately or together, optimal alignments confirmed the alignment described above, except for a few changes due to imprecise gap locations. For the complete (A+B+C) region, the Needleman and Wunsch[21] score was in all cases greater (by >6 s.d.) than the mean value obtained from comparisons with 30 randomly shuffled sequences (see Table 1); this value is higher than the cut-off value of 3 regarded as indicating statistically significant evolutionary relatedness[22]. Region A, when considered alone, was also aligned as expected, with variable statistical significance; when included in a large comparison (A+B+C) which produced a very significant score, an optimal alignment similar to that shown in Fig. 2 was obtained between polyoma large-T and HPV-6 E1 sequences. Only region D was poorly aligned, as might be expected from its small size and from the large gap on its left side. Taken together, these results clearly indicate that the two classes of proteins are related within a region of 120 amino acids (residues 150–270 in Fig. 2) and further suggest significant similarities over at least 210 residues (positions 48–290).

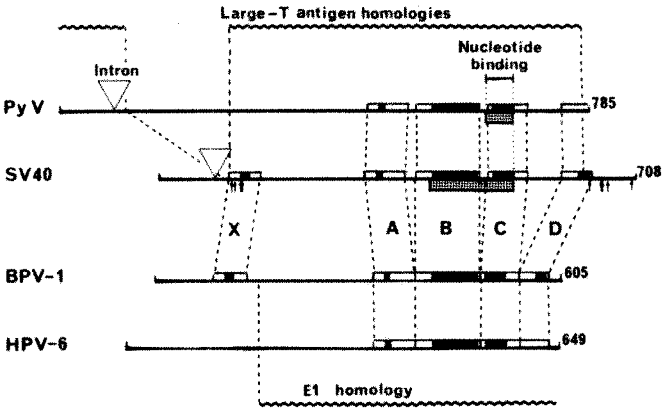

Fig. 1 Comparative maps of the large-T proteins of SV40 and polyoma viruses and the E1 proteins of two papillomaviruses. Sequences were first aligned on the basis of their regions of maximum homology (B; see Fig. 2 for the detailed sequences). Similarities were also detected in region A, C, D and X; solid areas correspond to clusters of homology over 40% analogous residues which were also in the computed optimal alignments (see Table 1). The total number of amino acids is indicated at the carboxy-terminal end of each protein. The positions of the labelled peptides released by CNBr cleavage after affinity-labelling of large-T proteins with periodate-oxidized ATP[16,24] are indicated by stippled areas. The location of the intron in the gene for large-T is indicated by an open triangle, and arrows show the positions of the main phosphorylated amino acids in SV40[25]. Wavy line indicates regions of homology within each class of proteins.

We also noted that residues which have a key role in protein structure, because of their charge (acidic or basic), size (glycine), reactivity or conformation (proline) are the most frequently conserved. For example, throughout the entire (A+B+C) region of homology (see Fig. 2), 53% of prolines, 47% of glycines, 44% of lysines, 40% of phenylalanines and 35% of aspartates are conserved between the E1 protein of PBV-1 and the large-T protein of polyoma. Conservative changes (serine to threonine, arginine to lysine, aspartate to glutamate) were also frequently observed. These observations suggest that the three-dimensional conformation of the E1 and large-T proteins might also be similar in these regions. Comparison of secondary structures and local exposure to solvent, using the methods of Garnier *et al.*[13] and Hopp and Woods[12], supported this hypothesis. Figure 3 shows that the computed hydrophilicity profiles were similar in regions B and C. Although the algorithm that we used to predict secondary conformations gives only a 50% probability[12], we consider it significant that, in regions where it predicts the same conformation for all three proteins of one class, this structure is also encountered in the other class. In region B, an amino-terminal (loop/pleated sheet/loop) pattern and the carboxy-terminal α-helix seem particularly significant. Secondary structure predictions for region C are not uniform, especially for E1 proteins, and thus are difficult to interpret with confidence, but they do suggest a common amino-terminal structure (loop/pleated sheet/loop).

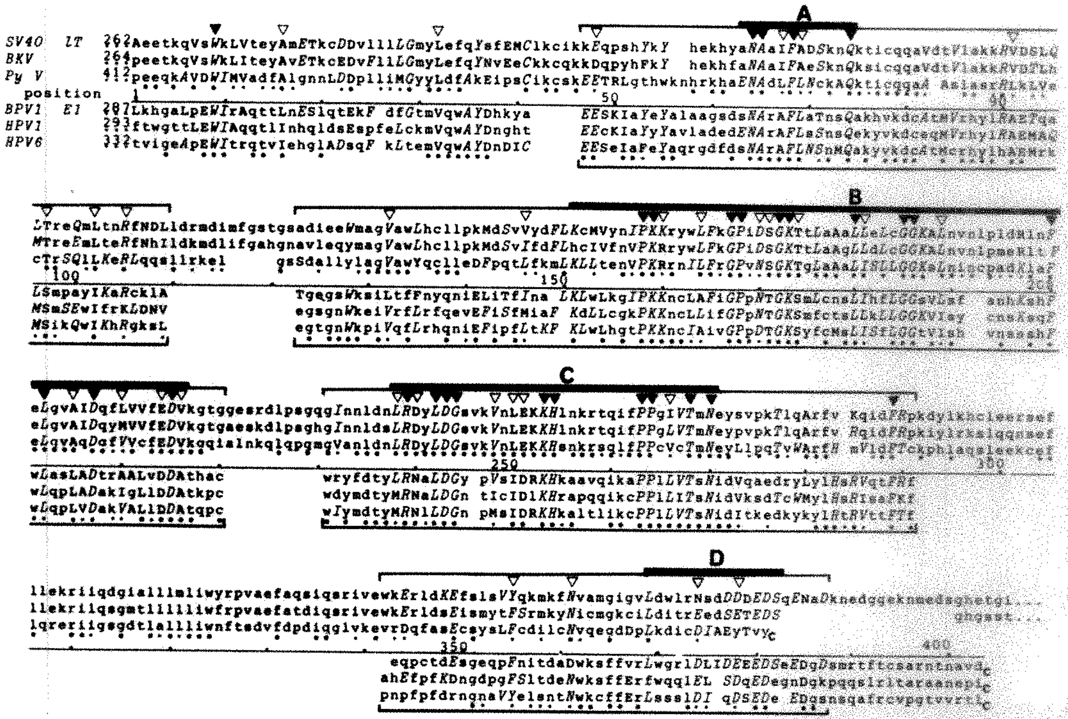

Fig. 2 Alignment of the carboxy-terminal half of the E1 protein from each of three papillomaviruses with the large-T sequences of three polyoma viruses. The more significant optimal alignments made by computer (see Table 1 and text) were retained and slightly modified, especially at the gap borders, to account for the internal homology within each class of proteins. The one-letter amino acid code is used: A, alanine; C, cysteine; D, aspartate; E, glutamate; F, phenylalanine; G, glycine; I, isoleucine; K, lysine; L, leucine; M, methionine; N, asparagine; P, proline; Q, glutamine; R, arginine; S, serine; T, threonine; V, valine; W, tryptophan; Y, tyrosine. Capital letters represent either homology (italics) or analogy (defined as in Table 1) between at least one protein of the large-T class and one of the E1 group. Triangles indicate homology (solid) or analogy (open) between the six sequences. Beneath each set of proteins are also shown homologies (large dots) or analogies (small dots) within a given class. Brackets enclose the regions A, B, C and D (see Fig. 1); the clusters of homology defined in Fig. 1 are underlined. The position in the protein sequence of the first amino acid is indicated at the left-hand side.

Table 1 Comparison of large-T and E1 amino acid sequences

Sequences compared		Agreement with general alignment in region:					
Large-T	E1	A	B	C	D	% Homology	*n* (s.d.)
SV40 295–555	BPV-1 320–550	–	++	++	ND	19.5	+6.28
PyV 440–700	BPV-1 320–550	–	++	++	ND	21.3	+7.18
PyV 440–700	HPV-6 370–600	+	++	++	ND	22.6	+6.13
SV40 390–650	BPV-1 375–605	ND	++	++	–	17.4	+1.84
PyV 525–785	BPV-1 375–605	ND	++	++	–	21.3	+2.74
PyV 525–785	HPV-6 429–649	ND	++	++	–	17.0	+2.51
SV40 305–365	BPV-1 325–385	+	ND	ND	ND	15.7	+0.42
PyV 445–515	HPV-6 370–440	++	ND	ND	ND	18.5	+2.21

PyV 530–630	HPV-6 430–530	ND	++	++	ND	25.0	+7.73
SV40 440–540	BPV-1 440–540	ND	ND	++	ND	20.0	+2.67
PyV 590–690	HPV-6 480–580	ND	ND	++	ND	18.0	+2.11
SV40 550–650	BPV-1 505–605	ND	ND	ND	+	16.0	+1.61
PyV 685–785	HPV-6 549–649	ND	ND	ND	–	18.0	+2.08
SV40 100–150	BPV-1 80–130	ND	ND	ND	ND	18.0	+1.53

The statistical significance of the homologies shown in Fig. 2 was determined by scoring computer optimal alignments. The program used[20] optimally aligns two sequences and calculates both a value for the distance between them and a Needleman and Wunsch[21] alignment score. The distance value for a pair of residues is thus 0 when they are homologous, 3 when they are unrelated, and 2 when they are analogous. The pairs A-I, A-L, A-V, D-E, D-N, F-Y, I-L, I-M, I-V, K-R, L-M, L-V, M-V and S-T correspond to the most frequent changes observed between pairs of residues from large-T or E1 proteins in their homologous regions; they were considered to be analogous, as they also conserved the charge, size, hydrophilicity or aromatic character of the residue. A penalty value of 6 was applied for each gap, plus the number of residues in the gap. The Needleman and Wunsch score obtained for the optimal alignment between two sequences was then compared with the mean value obtained from 30 comparisons of jumbled sequences of the same length and composition; the difference (*n*) measures the statistical significance of this optimal alignment, expressed as s.d. For this comparison, large-T or E1 polypeptides were cut into segments of various length; these are indicated by the positions in the protein of the first and last residues. Agreement between the optimal alignments that were computed and the general alignment presented in Fig. 2 is indicated as follows: –, <50%; +, 50–80%; ++, >80% correspondence with respect to the different regions defined in Figs 1 and 2 (ND, not determined). The last line refers to region X (see Figs 1 and 4). PyV, polyoma virus.

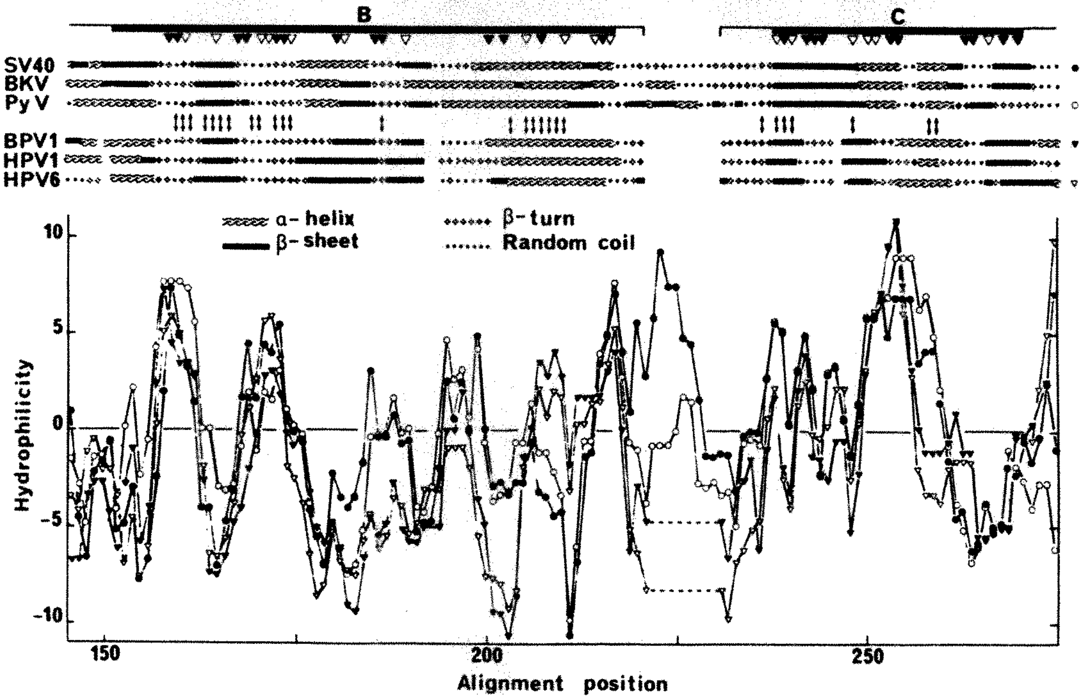

Fig. 3 Predicted secondary structure and exposure to solvent in the homology regions B and C. Local hydrophilicity values were computed from hexapeptide averages as described by Hopp and Woods[12] (●, SV40; ○, polyoma; ▼, BPV-1; ▽, HPV-6). Secondary conformation was predicted according to Garnier *et al.*[13]. Regions B and C, and homologous or analogous positions for the six proteins, are indicated as in Fig. 2. Arrows mark positions of structural identity.

Homologous domains B and C correspond to the segments of highest amino acid similarity within each class of proteins[3,4,10]. These regions probably include the active sites of the large-T molecules. The ATPase activity of SV40 large-T is inhibited by a monoclonal antibody whose epitope is precisely located within B[14,15]. In this region, homologies were also described between the large-T proteins and the *recA* protein of *Escherichia coli*[23], which also carries an ATPase activity. On the other hand, a nucleotide-binding activity for this region was revealed by affinity-labelling of SV40 and polyoma large-T proteins[24]. This binding site appears to be distinct from the ATPase catalytic site on the basis of the differential effects of various antibodies and mutations, and it was mapped to within region C by cyanogen bromide cleavage of the labelled protein (polyoma large-T, peptide 230–269 in Fig. 2; see Fig. 1)[16].

The other homologies detected are not of comparable significance. Region D is not well conserved between the large-T proteins of polyoma and SV40 viruses; it does contain, however, a stretch of acidic residues interspersed with serines that is also found in the large-T proteins of SV40 and BK virus. This is the most hydrophilic region in all these proteins, and one of the two serines in the SV40 large-T protein is phosphorylated[25]. The E1 sequence of BPV-1, but not that of the other papillomaviruses, shows another region of homology with the large-T proteins (region X; see Figs 1, 4) which contains a highly hydrophilic cluster of conserved residues corresponding to the same predicted conformation: a hydrophilic loop around the sequence Thr-Pro-X-Lys-(basic)-(basic)-(basic), followed by an α-helix. The region is rich in serine residues on its amino-terminal side, some of them being phosphorylated in SV40 large-T[25]. One might speculate that these similar features, found at the same relative positions in the different protein sequences, might also be phosphorylated in the E1 protein.

The conservation of functionally significant sequences within a common polypeptide architecture described here suggests that the E1 proteins have a role similar to that of the large-T proteins. The latter are multifunctional, acting in the establishment and maintenance of oncogenic transformation, the initiation of viral DNA replication and the regulation of early transcription during the lytic cycle[17]. The structural similarities observed suggest that, of the known biochemical properties of large-T proteins, at least two (ATPase and nucleotide-binding activities) might also be exhibited by the E1 proteins. At least in the case of polyoma virus, the activity of large-T protein in cell transformation does not require these two properties, as a truncated form which lacks the entire carboxy-terminal half of the molecule (including regions A to D), performs all the functions of the full-length protein[26,27]. This is in agreement with two recent observations on the role of the E1 gene which suggest that it controls the plasmidial maintenance and autonomous replication of papillomavirus genomes in transformed cells[18,19].

Thus, like the large-T proteins, the E1 proteins might be involved in the initiation of viral replication. The 'minichromosomes' of polyoma and papillomaviruses have the same chromatin structure as the cellular genome[17,28,29] and depend on the cellular machinery for their replication. Thus, the common features detected in the E1 and large-T proteins might be general properties of proteins involved in the control of initiation of cellular replicons in higher eukaryotes.

We thank E. Schwartz for communication of the HPV-6 sequence before publication, M. Yaniv and O. Danos for critical

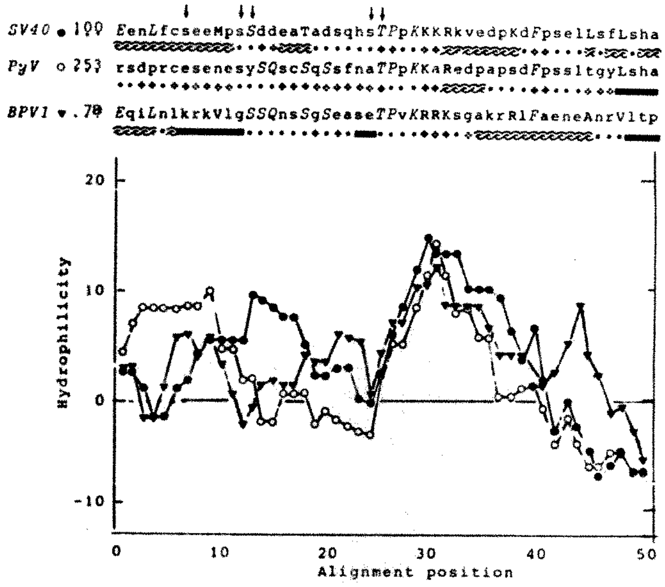

Fig. 4 Region X, another region of similarity between polyoma virus and SV40 large-T proteins and BPV-1 E1 proteins (see Fig. 1). The aligned sequences are given as described for Fig. 2. The predicted secondary structure and hydrophilicity profiles are also presented as in Fig. 3. Arrows above the SV40 sequence indicate the phosphorylated amino acids[25].

reading of the manuscript, R. Seif for helpful discussions, and especially F. Cuzin who wrote the Apple II programs used in this work and helped in the preparation of the manuscript. Special acknowledgements are also due to J. M. Claverie for introducing us to the alignment program used in this work and for hospitality at the Centre de Calcul Scientifique at the Institut Pasteur, Paris. This work was made possible by grants from the CNRS.

Reduction of the minimal sequence for initiation of DNA synthesis by qualitative or quantitative changes of an initiator protein

Gian Paolo Dotto* & Norton D. Zinder

The Rockefeller University, New York, New York 10021, USA

Initiation of DNA synthesis at an origin of DNA replication involves complex protein–DNA interactions that are still poorly understood. Some of these interactions are highly specific and involve proteins (initiator proteins) thought to be essential for regulation of the initiation process because of their rate-limiting activity[1]. We show here that both qualitative and quantitative changes in one of these proteins have profound effects on protein–DNA interactions at an origin of DNA replication, and are sufficient to reduce to less than one-third the minimal sequence required for initiation. The general implications of these findings are discussed.

Viral strand replication of the filamentous, single-stranded DNA phage f1 (fd, M13) occurs by a rolling circle mechanism[2] which is initiated and terminated by gene II protein, a specific, virus-encoded endonuclease[3]. The levels of this protein inside f1-infected cells remain low through the action of gene V protein, a viral, single-stranded DNA-binding protein that is able to repress gene II mRNA translation[4,5]. Regulation of gene II protein activity (and f1 DNA replication) is crucial to the unique life cycle of the phage[6]; unlike other bacteriophages, the f1-infected cells continue to grow and produce phage indefinitely, f1 growth being finely tuned to that of its host.

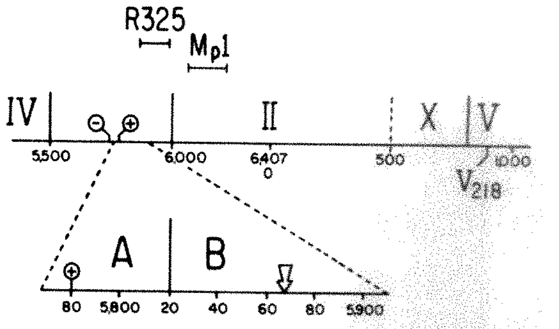

Fig. 1 Map of the f1 genome in the region of interest[6]. Roman numerals, f1 genes; between genes IV and II, intergenic region; ⊕ and ⊖, origin of synthesis of viral (plus) and complementary (minus) strand, respectively. Numbers indicate nucleotide positions on the f1 map[17,18]. V_{218}, map position of the V_{218} mutation in R218[12]. The f1 functional origin is shown in detail (map positions 5,769–5,909)[7,19] with its two domains, A and B[8]. ⇩, *Hae*III G/D site, used to construct R209[10] and Mp1[11]. The upper lines indicate the minimal fragments from Mp1 or R325 that were active in rescuing the R218/f1 phage; they extend, respectively, from map position 5,869 to 5,996 (R325; *Hae*III G/D to *Nci*I site) and from position 6,065 to 6,218 (Mp1; *Dde*I sites). Marker-rescue experiments with purified fragments annealed to R218/f1 single-stranded DNA were performed as described elsewhere[12,20] and fragments were considered positive which induced a 20-fold or more increase in clear-plaque production over background. R218 has been described previously[12]. R325, an independently isolated clear-plaque derivative of R209, was used in all marker-rescue experiments. A clear plaque resulting from one such experiment (using the R325 *Eco*RI to *Bam*HI fragment annealed to R218/f1 single-stranded DNA) was purified as a way of recloning the R325 mutation into an R218 background. The resulting phage (R330) was used for all further experiments.

Gene II protein interacts with the phase 'functional origin'[7,8] (Fig. 1), a region consisting of a stretch of 140 nucleotides required for viral strand replication. Two domains can be identified[8] (Fig. 1). Domain A, about 40 nucleotides long, is absolutely required for replication and can be considered as the 'core' of the origin. It contains three partially overlapping sequences[7–9]: (1) the *in vitro* recognition sequence for gene II protein; (2) a sequence required for initiation of plus-strand synthesis (initiation signal); (3) a sequence required for its termination (termination signal). Domain B, 100 nucleotides long, is required exclusively for initiation. Disruption of domain B by either deletions or insertions does not abolish the origin's function completely but reduces it to ~1% of its original level (biological activity of the origin was measured in a chimaeric ori-plasmid system, using f1 wild type as helper phage)[8].

Paradoxically, the site most frequently used for cloning in the filamentous phage vectors (f1 *Hae*III G/D site) lies within domain B[10,11]. A possible explanation for the good growth of these vectors would be that they contain mutations elsewhere in their genome which can compensate for the disruption of domain B. We have recently confirmed this possibility for one of our cloning vectors, R218 (ref. 12), and have now compared R218 with two other such vectors, R325 and Mp1. R218 and R325 are two independent, clear-plaque derivatives of an original phage, R209, that was constructed in our laboratory by inserting an *Eco*RI site (4 nucleotides) at the f1 *Hae*III G/D site[10]. Mp1 was constructed by Messing *et al.*[11] by inserting a fragment of *lacZ* (800 nucleotides) at the equivalent M13 site. R218, R325 and Mp1 replicate as efficiently as f1 wild type. However, when the 'functional origin' of one of these phages (R218) is extracted from the phage and used to replace the origin of f1 wild type, the resulting recombinant phage (R218/f1) can barely replicate[12]. When plated on normal *Escherichia coli* K38 cells, R218/f1 yields extremely turbid plaques. This property can be exploited in marker-rescue experiments to identify possible compensatory mutations elsewhere in the phage genome.

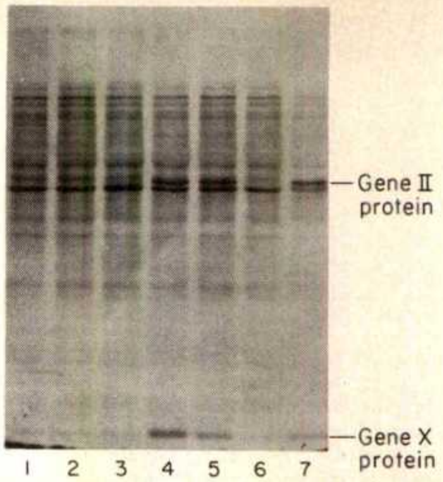

Fig. 2 Gene II protein production in cells infected with various phages. Lane 1, uninfected control; lane 2, R132 (gene II amber); lane 3, f1; lane 4, R13 (gene V amber); lane 5, R218; lane 6, Mp1; lane 7, R330. Exponentially growing *E. coli* K38 cells[21] were infected with various phages and pulse-labelled for 2 min with ^{35}S-methionine as previously described[12]. Samples were immunoprecipitated with gene II protein antiserum and analysed by electrophoresis in SDS/12.5% acrylamide gels[22,23]. The positions of the gene II and X proteins are indicated.

Using this approach, we found[12] that R218 contains a compensatory mutation (V_{218}) within its gene V coding region. The mutated gene V protein seems to retain its single-stranded DNA-binding activity, as phage is made, but loses its ability to repress translation of gene II mRNA. The resulting increased levels of gene II protein (~10-fold) inside the cell could account for the compensatory effect of V_{218} (ref. 12).

Analysis of R325 and its derivative R330 (described in Fig. 1) shows conclusively that increased gene II production is sufficient to overcome the negative effects of insertions in the phage origin. These phages, like R218, contain a mutation in their genome able to restore good growth of R218/f1. Marker-rescue experiments (Fig. 1) and nucleotide sequencing show that the mutation (II_{325}) lies upstream of gene II and consists of a single G to T substitution at position 5,977. This change lies within a sequence of the gene II mRNA leader ($U_5G_4CU_4$) which, because it seems to be unique, was suggested to be the target for translational repression by gene V protein[13]. Here we demonstrate directly the importance of this region for the regulation of gene II expression by showing that II_{325} (in R330, Fig. 2; and R325, data not shown) leads to overproduction of gene II protein in amounts similar to those observed with V_{218} (Fig. 2). Gene X protein, a product of internal initiation within gene II[14], also seems to be overproduced (Fig. 2).

Mp1 also contains a compensatory mutation which, however, does not lead to gene II protein overproduction (Fig. 2). Marker-rescue experiments (Fig. 1) show that the mutation (II_{Mp1}) lies in the gene II coding region. Nucleotide sequencing reveals a G to T substitution at position 6,125, leading to a methionine to isoleucine change (codon 40) in the gene II protein. This structural change in gene II protein has compensatory effects remarkably similar to those observed with increased gene II protein production.

Quite surprisingly, for both types of mutations, not only is the negative effect of insertions in domain B completely overcome, but domain B itself is rendered altogether dispensable. This is revealed by the analysis of chimaeric ori-plasmids containing f1 origins in which domain B is partially or totally deleted[8] (Table 1). These origins show only 1% residual biological activity relative to control (biological activity was measured as described in Table 1 legend), when f1 wild type is used to provide, in *trans*, all the necessary viral gene products. However, when the same origins are tested using R218, R330 or Mp1 as helpers, they are fully active. With Mp1 helper, mutant origins may even be more active than with the other phages.

Table 1 Biological activity of various f1 origins

	Phages (PFU ml^{-1})			
Plasmids	f1	R218	R330	Mp1
pD38 (A^+, B^+)	4×10^{10}	1.8×10^{10}	2×10^{10}	9×10^{8}
pD48 (A^+, B^-)	1.2×10^{12}	4×10^{10}	2.7×10^{10}	2×10^{8}
Δ+41, 70 (A^+, B^-)	2×10^{12}	5×10^{10}	4×10^{10}	6×10^{9}
Δ+29 (A^-, B^-)	3×10^{12}	1×10^{12}	2×10^{12}	1.5×10^{12}

The chimaeric plasmids used, containing the f1 functional origin or some of its parts, have been described previously[8]. A and B refer to the presence of an intact (+) or disrupted (−) domain A and B, respectively, in the various plasmids (see text and Fig. 1 legend). Phage yields were obtained as described previously[7] by infecting K38 cells that harboured the various plasmids. The ability of these plasmids to interfere with phage replication (decreased phage yields) gives a measure of the biological activity of the f1 origins that they contain[16] in the presence of the different phages. PFU, plaque-forming units.

In conclusion, we have shown that both qualitative and quantitative changes in an initiator protein can have a profound effect on the minimal sequence required for initiation of DNA replication. These findings may be of general significance and might even bear on recent, apparently contrasting, speculations concerning the role of increased production or structural alteration of certain key cellular proteins in disrupting the control of cell growth[15].

We thank R. E. Webster for the valuable gift of gene II protein antiserum, and P. Model and K. Horiuchi for critical reading of the manuscript. The work was supported by grants from the NSF and NIH.

Errata

Constraints on the neutron lifetime from triton β decay

J. Byrne

Nature 310, 212–213 (1984)

IN the fourth paragraph on page 212, the end of the second sentence is incorrect. It should read 'as a candidate for a neutrino mass search', not 'neutron mass search'.

Unusual DNA sequences associated with the ends of yeast chromosomes

R. M. Walmsley, C. S. M. Chan, Bik-Kwoon Tye & T. D. Petes

Nature 310, 157–160 (1984)

THE first author's name is incorrectly given as Richard W. Walmsley; the initial should be M, not W.

Ideology in archaeology

Warwick Bray

Religion and Empire: The Dynamics of Aztec and Inca Expansionism.
By Geoffrey W. Conrad and Arthur A. Demarest.
Cambridge University Press: 1984. Pp.266. £25, $49.50.

MOST archaeologists, once you come to know them, are quite normal people. They read newspapers, discuss politics, fall in and out of love, and are as irrational and prejudiced as anybody else. In their everyday lives they recognize that the world is a complex and ever-changing place, where human conduct is governed by emotion as well as reason. And yet, these same people, when they write professionally about extinct societies, depict an ordered world in which human behaviour (that is, the raw material of history) develops according to deterministic laws which owe more to Leslie White, Julian Steward or Karl Marx than to evolutionary biology. Ask an anthropologist what caused the industrial revolution, and you will probably get a complicated answer. Ask the same person what caused the urban revolution and the growth of political states, and all too often the reply will be "population pressure", "environmental stress" or some other neat and simple explanation.

At this point a historian (who has read his Machiavelli, and who studies the actions and words of real people, not theoretical abstractions) begins to shake his head and to say that archaeologists have very naive ideas about causality. The archaeologist replies that the historian is unscientific, subjective, and that he corrupts the innocent by passing off creative fiction as historical truth. And there the dialogue usually ends, though each party, in quieter moments, may admit that the other is at least partly right.

Because of the way the subject has developed across the Atlantic, most archaeologists in the United States have little training in history, philosophy or logic. As Conrad and Demarest remark,

> During the past two decades cultural materialism, in one form or another, has been the dominant theoretical approach in New World archaeology. Accordingly, environmental factors involved in state formation and expansion have been much discussed and explored . . . some of the ecological explanations of Precolumbian imperialism have been rather simple-minded deterministic themes which assume environmental pressures to be the *only* major causal forces involved in cultural evolution.

With this complaint I entirely agree, and I applaud the authors' intention to reintroduce ideology (or rather the manipulation of ideology by the governing class) as one of the agencies of social and political change.

The terms of reference are set out in the first half of the book, which describes the rise of the Aztec and Inca empires and their equally dramatic breakup in the face of European invasion. These chapters provide a balanced and well-written survey, though very similar accounts of the Aztec story have been in print for some years, and Conrad's views on "split inheritance" (whereby the Inca ruler's power and title descended to his heir, while his wealth remained the property of the dead man's kin group) have already been the subject of a great deal of discussion in the professional literature.

New or not, these sections are a necessary prelude to the theoretical discussion which follows. The authors conclude that the success of the Aztecs and Incas was due in large part, though not exclusively, to ideological innovation. In particular, they single out the intensification of human sacrifice and the cult of the warrior sun by the Aztecs, and the combination of divine rulership and split inheritance in Inca Peru. I accept Conrad and Demarest's evaluation of these specific phenomena, but, even in societies where there is no clear separation between the religious and the secular, this takes an unduly narrow view of ideology. My dictionary defines the word as "the manner of thinking characteristic of a class or individual". To be effective, a national ideology has first to be made acceptable by a process of enculturation or indoctrination, as any politician well knows (was not Waterloo won on the playing fields of Eton?). A walk around the streets of Belfast will quickly show how difficult it can be to separate religious from political ideology, but I doubt whether any successful empire was built on religion alone. Conrad and Demarest are careful to explain that they are against all monocausal explanations, and that ideology was just one factor in the growth of the Aztec and Inca empires, but they sometimes write as if ideology was the single main stimulus of success. This is arguable, to say the least.

Burden of labour taxation — Incas carrying the produce of state-owned fields to imperial storehouses. An imperial official (centre) directs the work.

Drawing by Guaman Poma, reproduced from *Religion and Empire.*

In their later chapters the authors move from the specific to the more general, in the search for a theoretical framework to explain the emergence of states and the rise of empires. This is one of the bread-and-butter problems of cultural anthropology, so it is fair to ask how — if at all — Conrad and Demarest have improved on previous studies.

In their discussion of socio-political evolution, the biological analogy is never far away. Culture is seen as an adaptive mechanism, responding to particular pressures from the environment (which includes the "climate of opinion" — that is ideology — as well as the physical universe). Thus, "the Mexica and Inca ideological reforms of the early fifteenth century were highly successful adaptive responses to the natural and cultural environments". These responses, successful at first, became maladaptive in the long run, and were instrumental in bringing down the very societies they had helped to create. This is fine, up to a point. But why, given much the same environmental pressures, did the rivals of the Aztecs and Incas not come up with equally effective adaptations? If the answer is simply that the Aztecs and Incas had better leaders (or better theologians), we are back to the Great Man view of history, which is anathema to all processual archaeologists. And why, if the Aztecs and Incas had adapted once, did they not readapt when their reforms had outlived their usefulness? Also, how do the invaders fit into the scheme? Cannot the Spanish conquest be seen as a trial of strength between European and native ideologies, rather than between Spanish and Indian armies?

Most of all, the evolutionary analogy raises questions of "causality" of the kind familiar to historians as well as to anthropologists and archaeologists. Conrad and Demarest give a lot of space to this question, without carrying conviction or offering much hope for the future. In biological evolution the question "What causes elephants?" is meaningless. Perhaps it is just as pointless to ask what "causes" states or empires. Conrad and Demarest do a lengthy demolition job on the ecological determinists, the cultural materialists of the Marvin Harris school, and even on the orthodox Marxist theoreticians (though they show more sympathy for the "structural Marxism" of Godelier and his revisionist colleagues). These criticisms were well worth making, but where do we go from here? To revert to the authors' own biological analogy, we need a theoretical model in which the same phenomenon can simultaneously be an adaptive response (to the previous adaptive responses?) and also a "cause" of change. This, of course, denies the existence of prime movers. Some biologists and anthropologists would argue that, for all its imperfections, some form of systems model comes nearest to satisfying the requirements, but this possibility is never seriously discussed.

Overall, *Religion and Empire* looks backward, to yesterday's problems, rather than forward towards the future. It is a thought-provoking book, but as a contribution to the debate on causality in human history it offers few solutions. Nor does it suggest how the archaeologist, with no documentary information to help him, can even begin to reconstruct the nature of past ideologies, let alone build ideology into his explanatory model. ☐

Work with nucleic acids

Jeffrey Williams

Techniques in Nucleic Acid Biochemistry.
Techniques in the Life Sciences,
Vol. B5.
Elsevier: 1984. $55.

For those who do not already know the series, it should first be pointed out that *Techniques in the Life Sciences* takes a somewhat unusual form. Each volume consists of a number of pamphlets, loosely held within a plastic box. The rationale is that such a format will allow the publication of supplements and replacements to keep each volume up to date; indeed, with no secure method of retaining individual pamphlets within the box, and with the high loss rate observed for methods sheets in most laboratories, a steady supply of replacements seems likely to prove a necessity.

This is the final volume in the Biochemistry Section of *TLS* (the other, which still continues, deals with physiology, while a Cell Biology Section will be launched next year) and it illustrates the usual advantages and disadvantages of a multi-author technical manual. Because almost all of the authors are recognized experts in their particular techniques, the methods presented are thoroughly tried and tested. The main fault is the enormous variation in the depth of technical detail. Thus the "shotgun" method of DNA sequence analysis is described down to the last salt concentration in a contribution which should find a place above the bench of all aspiring long-distance sequencers. In contrast, the section on RNA sequence analysis is purely a review which, while well written, contains no technical descriptions of any one sequencing method.

These two contributions represent the extremes and most of the articles succeed in the difficult task of combining a literature review with a more-or-less comprehensive methods section. Thus the articles on RPC-5 chromatography of DNA, restriction enzyme purification, restriction enzyme mapping, cosmid cloning, mRNA-DNA hybridization and calcium-phosphate-mediated DNA transformation constitute very useful descriptions of important techniques. There are contributions on genomic cloning in bacteriophage and in yeast which, although predominantly designed to be review articles, give a certain amount of technical information. Finally there are two sections — on bacterial expression vectors and on the analysis of eukaryotic enhancer sequences — which are primarily reviews of work from within the authors' laboratories.

The style of the volume is somewhat akin to the manuals emanating from Cold Spring Harbor Laboratories, but it is a multi-author work and this places it firmly in the mould of a series such as *Methods in Enzymology*. Where the latter is much more successful is in enforcing consistency upon the individual authors and the overall impression is of a valuable concept which in practice still has not quite found its feet. ☐

Jeffrey Williams is at the Mill Hill Laboratories of the Imperial Cancer Research Fund, London.

That strange fellow, Mr Newton

A. Rupert Hall

In the Presence of the Creator: Isaac Newton and His Times.
By Gale E. Christianson.
Free Press, New York: 1984. Pp. 623. $27.50.

ONE OF Isaac Newton's French contemporaries and author of the first textbook on calculus, the Marquis de L'Hôpital, is said to have asked of him: "does he eat & drink & sleep, is he like other men?". Newton's close friend, the philosopher Locke, wrote of him: "Mr Newton is really a valuable man, not only for his wonderful skill in mathematics, but in divinity too . . .". The historian–bishop, Gilbert Burnet, called Newton "the *whitest* soul I ever knew".

Adulation of Newton's character was far from universal in his own lifetime, however: the diaries of Robert Hooke and John Flamsteed, and the letters of Leibniz, contain some of the harshest language a seventeenth-century gentleman (other than Swift) could bear to pen. Newton's successor in the Lucasian Chair, William Whiston, recorded his as "the most fearful, cautious and suspicious temper" he had ever known. Recent writers on Newton the man have, on the whole, taken the side of Newton's enemies rather than that of his friends. At the best they have (following Keynes) emphasized his character as magus, mystic and seer, deducing even the concept of universal physical forces from the mystery of alchemy; at the worst they have found him dictatorial, deceitful, violent, neurotic, a fit subject for the psychohistorian's couch if not the straitjacket.

Gale Christianson is not of the psychoanalytical school, but he discerns another powerful force in Newton's nature: social and personal ambition; "Newton had kept his private pledge to attain the recognition usually denied a lowborn yeoman's son" (p.383). He makes much of Newton's lack of arms, his family illiteracy, his status as a sizar at Trinity, in a way that shows a certain insensitivity to the habits of Newton's society. A sizar was not so very different from a gentle page in a noble household and many gentry could barely sign their names. If one underestimates the likelihood of upward mobility in a society, one is likely also to exaggerate the psychological effects upon those who, like Samuel Pepys and Isaac Newton, rise far in status.

Comparison is inevitable between this new biography and the even ampler one by R.S. Westfall (*Never at Rest*; Cambridge University Press, 1980). Westfall's book is a magisterial study of Newton the scientist based on a quarter-century of steady reading of Newton's manuscripts and publications; Christianson's is a human story in which the scientific achievements are briefly summarized. Rightly, it leans heavily for fact and interpretation on the post-war Newton industry, though Christianson himself must have passed many hours in the Cambridge University Library and other places eliciting obscure information about Newton's life and his relations with his contemporaries.

On the scientific side Christianson is sometimes shaky: Jupiter's were not the only known planetary satellites in Newton's lifetime nor was Descartes seeking, with aspherical lenses, to correct chromatic aberration. Sometimes his eagerness to be in the modern swim verges on absurdity, as when he argues from Robert Boyle's presentation of copies of a book to three Cambridge men (Barrow, More and Newton) in 1673 that all four were "Hartlibians". He spoils a famous story by mistranslation: "I *recognise* the lion by his claw", not "from the claws of the lion" (p.416), is what Johann Bernoulli wrote. Older English readers know that £1.14s and 34s are the same sum.

On the human side Christianson gives a fair picture of Newton's personality, his friendships and enmities, his swift (but not unpainful) ascent to fame and, belatedly, fortune. He dismisses the idea that Newton's character deteriorated with age and power: "The political and professional offices Newton held, in combination with an unassailable reputation, merely enabled him to expand the scale on which his Jovian fits of passion were played out after 1700" (p.500). Combative temper and vindictiveness were present from the start. The picture is gloomy and obsessional, Newton was "a tragic figure of towering dimensions" (p. 499). This is too simple and extreme. Newton was *also* (from evidence Christianson largely omits) a courteous host, a raconteur, indulgent to foreign visitors (even at Cambridge), a man of the world, patient with those labouring under intellectual difficulties, and a Lincolnshire patriot.

Above all, Newton was an intellect; agreed, a formidably serious intellect. To study this, one must go back to Westfall and others. Christianson's is in many ways an excellent, balanced and thorough biography. But the modern tale of Newton the ogre-magician is about as historical as the story of Alfred and the cakes: it is probably not true, and it is certainly not relevant. ☐

A. Rupert Hall is historical adviser to the Wellcome Trust and Emeritus Professor of the History of Science and Technology in the University of London.

New in paperback

Women Scientists in America: Struggles and Strategies to 1940, by Margaret W. Rossiter. Publisher is The Johns Hopkins University Press, price is $10.95, £9.75. For review see *Nature* **302**, 761; 1983.

Intelligence brought into sight

Horace B. Barlow

The Logic of Perception.
By Irvin Rock.
MIT Press: 1984. Pp.365. $22.50, £21.40.

WHEN a sensory physiologist suggests a mechanism for a perceptual phenomenon to a psychologist, the latter's response is usually predictable: he may or may not express polite interest, but sooner or later he will certainly say "Ah, but I'm afraid your idea does not explain XYZ"; XYZ will turn out to be a slight modification of the original phenomenon which seems trivial to the physiologist, but which proves to the psychologist that the explanation offered is of little interest or importance. The good thing about Irvin Rock's book is that it describes explicitly many of the XYZs — the perceptual phenomena that are prominent in the minds of psychologists but not yet explainable in terms of physiological mechanisms. Because physiology, psychology and artificial intelligence are more and more seeking explanations of the same phenomena, the subject matter of the book is very timely.

Irvin Rock describes himself as "originally an ardent advocate of the Gestalt point of view", but in this book he argues that "perception is intelligent in that it is based on operations similar to those that characterize thought". It is tempting and to some extent justifiable to poke fun at him for having finally caught up with Helmholtz, who was emphasizing the importance of unconscious inference in perception well over 100 years ago. But Rock has done a service by describing clearly a large number of the phenomena to which Helmholtz's phrase applies, and he has done elegant experiments to sort out what features of the stimulus are necessary for the intelligent interpretations that the perceptual system makes. Thus he brings together an assortment of material that is potentially of great interest and value to sensory physiologists and those interested in computer simulation of vision. An account of one of these phenomena may give an idea of the subject matter of the book.

Look at a stereo-pair, either through a Wheatstone stereoscope, or better a dichroic pair viewed through red/green spectacles. When a good appearance of depth has been obtained, move your head from side to side: a vivid impression will be obtained that objects in the foreground move relative to objects in the background. The range of head movements possible with a Wheatstone stereoscope is just enough to obtain a good effect, but it is much better with the dichroic stereo-pairs recently available in Britain to eaters of Shredded Wheat. Now shut one eye and repeat the head movements: the relative movement of foreground and background vanish completely.

An explanation for these effects can be reached by considering that depth information from *binocular* parallax is concordant with depth information from *motion* parallax when looking at the real world, but for a stereo-pair both images are in the same plane, so there is no motion parallax regardless of the apparent depth of an object caused by its binocular parallax. One way to reconcile information from the two sources is to suppose that the objects move when the head moves; the required movement of foreground objects relative to background objects is that which will precisely nullify the expected motion parallax, and according to this hypothesis this is what one "sees". This is the explanation Rock gives, and it may be correct; but it is worth noting that the hypothesis has not so far specified the source of information to the perceptual system which leads it to expect motion parallax.

This expectation could arise from the willed head movement, from the vestibular organs or from the visual scene itself. The latter source is suggested by the following observation made by Professor P.A. Merton at his breakfast table, well-equipped with its stereoscopic Shredded Wheat box: rotation of the stereo-pair around a vertical axis gives almost as vivid an impression of relative movement as head motion. Such a rotation, especially if executed by someone other than the observer, could not evoke the expectation of motion parallax from the efferent signal for the movement, nor from the vestibular organs; hence it must arise from changes in the seen images themselves. Since it does not occur monocularly it cannot be the trapezoidal distortions associated with rotation, and (as Dr G. Mitchison points out), the most likely source is the changing gradient of disparities caused by rotation. It is ironic that Mitchison has recently shown (with Professor G. Westheimer) that the perceptual system is extraordinarily insensitive to disparity gradients when tested directly, but this does not prove that they cannot have indirect perceptual consequences.

Another comparable phenomenon described by Rock is the "anorthoscopic display" in which a line moves behind a slit and is therefore shown serially as a succession of short line segments; under appropriate conditions this can be seen as a whole line moving behind the slit aperture. He describes an elegant experimental analysis of the stimulus factors required for the perception of the whole line. Another much-used example with a similar analysis is the "kinetic depth effect", in which a line that changes length as it changes orientation is seen as a rod rotating in three dimensions.

I confess that I found Rock's reasoning about these things less satisfactory than his exposition of them. It is precisely in this sort of area that sensory neurophysiology and artifical intelligence have interesting

21-1-87
A. Beth

things to say, but he has only taken in part of their message. For instance he describes lightness perception without mentioning the separate "on" and "off" system of the mammalian retina, which must surely be relevant to the perception of darkness as well as of lightness. He then goes on to say that the perception of lightness and colour appears to be "based upon information at the edges between regions of differing luminance or hue". That's fine of course, but how is this information extracted from the image and how is it represented in the brain? He talks of the direct detection of relative difference or ratio of luminances, but then suggests that "there is no need to invoke lateral inhibition". This takes one's breath away, for he does not propose any alternative mechanism for the very operations he recognizes are necessary. I think he must fail to realize that, however intelligent or "thought-like" the mechanisms may be, they are ultimately physiological. Surely it is best to proceed by building on the physiological mechanisms we already know about, rather than arguing as if physiological and psychological processes are mutually exclusive alternatives. Neurophysiological explanations are almost always incomplete, but the strength of physiology is that it is a growing science!

For these reasons I fear that Rock's discussions of mechanism are best ignored by physiologists, and I think the same advice can be given to those who approach the problem from the standpoint of image-processing and artificial intelligence. They will have been grappling with the problem of extracting and representing objects in images and will learn little from his reasoning about the phenomena he describes. But the book as a whole should not be ignored, for it gives valuable accounts of perceptual phenomena that are begging for further analysis in terms of neurophysiology and computer simulation. Rock's claim that perception is "shot through with intelligence" does not help much, but both perception and intelligence will be greatly illuminated if we can understand their neurophysiological and computational basis. ☐

Horace B. Barlow is Royal Society Research Professor in the Department of Physiology, University of Cambridge.

The Rock Art of Africa.
By A.R. Willcox.
Croom Helm, London/Holmes & Meier, New York: 1984. Pp.287.
£45, $69.50.

THE African continent, extending almost 4,000 kilometres both north and south of the Equator, boasts a singularly varied ecology that in turn supports a bewildering diversity of peoples, cultures and belief systems. For millennia the transmission of cultural values from one generation to the next has depended not upon the written word, but upon oral communication reinforced with music, dance, ritual practices and visual representations. It is with one aspect of the latter — paintings and engravings made on rocks — that the book under review is concerned.

The re-discovery and interpretation of African rock art sites, originally painted or graved by Stone Age hunter–gatherers and later by Neolithic pastoralists and Iron Age agriculturalists, has excited the curiosity and imagination of many of the subsequent colonists of the continent. All of them have added their own perspectives as to the age, origin and meaning of the art, resulting in a profusion of data of varying calibre written in many languages and often hidden in obscure journals.

It is against this background that Alex Willcox has marshalled the information for his book. Now in retirement from a career in quantity surveying, his writing has progressed systematically from the particular to the general. His first book was an area study, *Rock Paintings of the Drakensberg* (Max Parrish, London; 1956), followed by a more general *The Rock Art of South Africa* (Wageningen Press, Johannesburg; 1963), and now this compendium covering all of Africa. It is the most systematic and comprehensive amalgamation of data yet presented on the subject. Two previous attempts, *African Rock Art* by Berchard Brentjes (Dent, 1969), and *Rock Art of Africa* by Carson I.A. Ritchie (A.S. Barnes, Cranbury, New Jersey; 1979), were far less successful.

Each of the chapters devoted to a specific region is accompanied by maps, copious line drawings and black-and-white photographs of the predominant art styles, all conveniently juxtaposed to the relevant text. The 67 colour photographs, on the other hand, are sometimes disappointing in quality, and have been crammed onto 24 pages. Even more unfortunately, they have been omitted from the table of contents.

Although Willcox could not be expected to discuss in detail *all* the relevant literature, some omissions are surprising, and viewpoints which do not coincide with his own are somewhat cuttingly and not altogether fairly dismissed. Not everyone will agree with his interpretations, particularly on cultural diffusion and the relationship between the art zones, on the chronological correlation of the art styles, the ethnic identification of the artists and the underlying reasons for the art, but a well-referenced text at least refers readers to the models he eschews. Willcox describes his own model as an Aunt Sally for other archaeologists to shy at (p. 253), and shy they will.

Most contentious of his views is the persuasion, strongly expressed in his first book of almost three decades ago, that the motivation behind the art is essentially the pleasure derived from its execution. Indeed, although Willcox himself refers to a wide range of ethnographic practices connected with rock art, which are summarized and added to by Desmond Clark in an excellent foreword, he is curiously dismissive of this evidence in his final evaluation of the reasons why the art exists. The use of rock art as territorial and ownership marks, in rain-making rituals and in initiation, marriage and burial ceremonies, has been documented from all over Africa. Examples range from the Marghi of northern Nigeria to the Cuissis of Angola, the Oromo of the Harar plateau in Ethiopia to the Guanches of the Canary Islands, the Namia of southern Tanzania to the Bemba, the Butwa and Nyau secret societies of Zaire, Zambia, Zimbabwe and Malawi. Yet when it comes to southern Africa, Willcox is curiously reticent about the considerable amount of ethnographic evidence adduced by Lewis-Williams and others in linking San belief systems to the rock paintings. Whilst Willcox accepts symbolism as a possible component of the non-representational art which he ascribes to the later pastoral peoples, he dismisses the possibility of symbolism in the figurative art of the hunter–gatherers (p. 241). The now classic Levi-Straussian quote that animals are not only *good to eat* but also *good to think* is believed by Willcox to be wrong on both counts. He suggests instead that animals were painted because they were *good to see*. Whilst it is of course true that animals do have a special beauty, it is also undeniable that factors in addition to beauty and pleasure in a task well done were involved in their depiction.

At the start of the book, Willcox claims that the primary purpose of the study of rock art is as a branch of archaeology (p. 9), and here, perhaps, lies the limitation of his approach. As emphasized by Desmond Clark in the foreword, the archaeologist needs to elicit the help of anthropologists, ethnographers, linguists and psychologists in seeking to use the evidence of still-existing peoples the better to understand their prehistoric forebears. Willcox himself observes that the study of art reveals aspects of man's nature not deducible from his material culture (p. 7).

Some idiosyncratic views apart, Alex Willcox's encyclopaedic publication will provide an indispensable source book for professionals and the interested public alike, and will stimulate a deeper awareness of the beauty as well as the scientific and communicative potential of this fascinating body of African art. ☐

Poor control for US information

The US Congress has put off legislation on the export of high-technology until after the election. Everybody's interest is that it should be given a clear lead from the administration when it returns.

THE US Congress, which leaves Washington to fight the presidential election at the weekend, will leave in a mess the rag-bag of unfinished legislation on the export of high-technology with which it has been wrestling for the past two years. And, for the time being, nobody will care. The universities will be for a few weeks free from anxiety about the interpretation of successive draft regulations from the Pentagon. Societies organizing conferences will be able to live for a few months longer with the practices with which they have become familiar on the participation of foreign nationals. Not even the administration will be deeply disturbed, for on the evidence of the opinion polls, there is every chance that it will be invited to return in January with a more compliant Congress, perhaps one less ready to listen to the doubts of those in the universities and industries of the United States, not to mention their opposite numbers elsewhere in the world, who believe that the past year's attempt to prevent the loss of technical information from the United States is inherently misconceived.

Balancing conflicting aspects of the national interest, any national interest, is always like walking a tightrope. Sure feet and physical fitness are essential (which means that governments must be decisive but also capable of administering what they decide). But it is just as important that the balance organs, with or without the assistance of the eyes (Blondel used to walk in a blindfold) should be keenly tuned, sensitive to the dangers of falling on one side or the other as well as to the signs that the body is out of balance (which means that governments regulating the export of technology must know the dangers of miscalculation in either sense). The worry about the past ten years, and the reason why that experience is a gloomy augury for the future, is that the Reagan Administration has shown flaws in all departments.

That a modern state must have a policy on technical secrecy is not, of course, in question. If there were no secrecy, the benefits of military innovation would flow freely to adversaries and, almost as alarming, to states which are to begin with unaligned but to which the advent of new military technology might seem a challenge. When (as in the eighteenth century) the pace of change in military technology was negligible, but wars were so frequent that new technologies were regularly on display, the need for secrecy (or technical espionage) was hardly noticeable. Now, all that has changed. For the past century, military powers have been compelled to increase their efforts to keep their secrets secret, often with remarkable success. The technology of the manufacture of nuclear weapons is even now less widely spread than it might have been, no doubt in part because nuclear weapons states have an interest that there shall not be too many others like them.

Challenge

The particular challenge of the past few years has been the way in which military and civilian innovations have become intertwined. Even as recently as in the post-war period of 1945–55, when it was already clear that civilian industry had much to learn from the military, civilian innovations were usually by-products of military innovations (jet engines, for example), with the result that the military people were well placed to regulate the speed at which new developments spread. It is too often forgotten that the change which has since come about, only symbolized by the development of transistors, has radically altered the relationship between military and civilian industry. It is now common for the cost of civil development programmes to be comparable with what the military have to spend. Although, historically, the development of the semiconductor industry based on silicon chips and their successors may have been stimulated by the need to miniaturize rocket-borne equipment, only a few years later the incentive came from the civilian side. In the United States, the process has been accelerated by the practice (constitutionally required) of putting military development out to civil contractors. The result has been a quarter of a century of heady technical development from which both partners have profited in their very different ways.

Two further complications have now arisen. First, as the United States is still somewhat disconcerted to discover, civil industry must make its way in markets which are inescapably international. There is no other means by which the technically innovative companies that keep the United States prosperous can pay for the cost of their innovations. So the knick-knacks which the Pentagon wants to buy turn out also to be on sale outside the United States, and in due course become accessible to other people's Pentagons. This circumstance is, of course, entirely maddening. Why should prosperity, on the face of things a just reward for ingenuity, be inescapably alloyed with the wider diffusion of innovation? And why should salt be rubbed in open wounds when it turns out that some of the beneficiaries of this technical diffusion are not potential enemies but, rather, allies who are even faster at organizing production, or piling one innovation on another? In the strictly commercial field, these are the questions that have so plainly irritated the US Administration in its attempts to win legislation on export controls. The same goes for basic research, where the administration has sought the benefits of openness and the security of selective secrecy. Its judgement has as a consequence been distorted — and its knowledge that something is wrong has undermined its capacity for clear action.

Muddle

None of this implies that there should be a bonfire of the regulations. Open licences for military equipment would plainly be absurd. So, too, would be open access to military research. The question of where to draw the line between materials that can and cannot be exported must however depend on a judgement of how much time will be spent by military competitors overseas in using similar techniques for the local manufacturer of comparable equipment, and on the likely relationship of that time-lag to the natural pace of development in the field. Nobody who has seen a micro-chip production line at work will think that the sale of a few of the products to a potential enemy is the equivalent of a gift of the technology, but plainly the architecture of a successful computer may be more sensitive. In the old days, merely four years ago, these were the principles underlying the strategic embargo list then in force. By seeking tougher rules without a philosophical basis for designing them, the Reagan Administration has replaced a workable set of rules which were at a few points absurd with a more comprehensive muddle.

What the United States (together with its military allies and commercial competitors, who are mostly the same) is most in need of is thus an agreed basis on which rules may be worked out as time goes on. The move towards self-regulation by corporations in the United States is a step in the wrong direction — and a recipe for endless uncertainty. The suggestion that there might similarly be a categorization of the research that people attached to universities carry out, with some of it kept secret or semi-secret as other people decide, is not a recipe for "stifling" research but for persuading academic people to pursue uncomplicated goals. On both counts, the result will be less productivity, commercial and intellectual. And the loser will be the United States. Naturally, an openly elected administration is bound to make the choice it thinks the best. On this occasion, unfortunately, the choice is being made irrationally, in the belief that it is possible to keep innovations secret for the rest of time while enjoying the fruits of their sale on the open market. □

Orphaned academy

Britain's scheme for a European academy deserves serious consideration.

THE only squib at last week's predictably somnolent meeting of European science ministers in Paris (see *Nature* 20 September, p. 197) was the British proposal that there should be a European academy of science. And that seems almost to have been an afterthought. The British delegation, embarrassed that its brief called for familiar cautious negativeness on any but the most modest proposals for strengthened collaboration, seems hastily to have hit on this wheeze to demonstrate goodwill. It seems not to have known of the European Academy of Arts, Science and the Humanities, based in Paris, to which Nobelists and some others belong. And by not warning them in advance, the British seem to have embarrassed even its friends. Yet the idea is appealing, even to some of those who regard trans-national institutions as an intolerable threat to national sovereignty. For the truth is that the European community of scholarship is potentially much larger than the sum of its parts, many of which are very small, while the cultural diversity of Europe suggests that such an academy would be an interesting institution. What follows is a recipe for those who would put flesh on the bones the British were rattling.

The first step is to make peace with the European institutions that have, in recent years, thought of themselves as embryonic versions of a European academy. CERN, the high-energy physics laboratory at Geneva, was the first in the field, but the visionaries who in the 1950s dreamed of incorporating other fields of scholarship have long since been replaced by people whose chief concern is where the next 100 million Swiss francs will come from. The European Molecular Biology Organisation (not to be confused with the laboratory of almost the same name at the same place, Heidelberg) has also used language of the same kind, and even has a system of elected personal membership built into its constitution. The European Science Foundation (at Strasbourg), potentially the chief beneficiary of the decision of last week's meeting to encourage stronger European research networks, more openly regards itself as the future European academy, but mistakenly. The foundation, which does splendid work on too small a budget, is as it stands essentially a club for European grant-making organizations, at best an academy of academies. As good a case could be made for the Institut des Hautes Etudes, outside Paris, which is supported by the French Government (with modest help from the European Science Foundation) but which is admirably free from chauvinism in its appointment of people. Whatever their virtues, all these institutions lack the essential attribute of an academy — that of being a self-electing meritocracy.

The designers of the new institution will also have to clear their minds about its function. Academies come in several different forms none of which is a ready model for a European institution. The secular function of academies, that of giving advice to governments, conspicuous in the United States and the Soviet Union but less so elsewhere, cannot apply when there is no single government on which to thrust advice. The conduct of research at a single location is similarly impractical, whatever may have been possible at the academy in St Petersburg in the eighteenth century or in Berlin when the old Kaiser Wilhelm Institute was at its peak. Of the functions of modern academies that could be adapted to a European canvas, the best outlets are the spending of modest sums on the support of scholarship by criteria which are entirely independent, the management of scholarly publications and the pursuit of excellence by repeated demonstration. Such an institution, if properly arranged, could serve to enliven European science in ways not yet foreseen.

But how would it be possible for a European academy to avoid the tokenism to which most kinds of international institutions are prone? Should members of the new institution be elected in proportion to the populations of its sponsor, or to their Gross National Product? Should Nobel prizewinners automatically become members, or be so *ex officio?* Should the presidency rotate among countries? And by alphabetical order or otherwise? Where should the social sciences fit in? Any one of these questions is by itself sufficiently daunting to persuade all but the enthusiasts that the effort would not be worthwhile. There is, however, a way in which these difficulties could be turned. Simply agree that for an initial period of, say, ten years, new members should be elected annually to a European academy by some outside body (for which purpose the European Science Foundation would serve well), but give the existing membership (after the first year) a veto. And then require that for the initial period, no new member should be older than, say, forty. To begin with, it is unlikely that such an organization would be able to do much more than organize occasional scientific meetings. Eventually, however, it might have won enough respect in the outside world, and have learned enough about its own quality, to be able to take independent and less familiar initiatives. And if, by evil chance, luck went the other way, nothing much would have been lost. □

Redundant department

Advocates of new US Government agencies include people who should know better.

RONALD Cape, chairman of Cetus Corporation, president of the Industrial Biotechnology Association and usually a level-headed spokesman for the industry, seems to have been overcome by the excitement of the Biotech '84 conference held earlier this month in Washington, DC. That at least is the kindest interpretation of his talk there, in which he called for the creation of a new federal agency in the United States charged with promoting biotechnology. Its first assignment would be to double the federal government's support for basic research in the life sciences, now some $2,900 million a year.

Cape is sure to qualify for this year's final round of the Bite the Hands That Feed Them Award with his complaint that the National Institutes of Health (which now spend $3,800 million a year on research and development, well over half of that on basic research) are too "fragmented" to meet the needs of biotechnology. The other reason advanced by Cape is, of course, the Japanese Peril. The Soviet Peril was enough to bring about the National Aeronautics and Space Administration, after all, and that was nothing compared with the threat of Japanese competition. "They did it to us in cars", he said. "They did it to us in tape recorders and TVs. And now they say they're going to do it to us again in biotechnology."

Cape may have been asking for trouble in citing these analogies. Once the Department of Biotechnology is established, presumably with Wally Gilbert as Assistant Secretary for Finance and Mark Ptashne as director of the media relations office, the Department of Automobiles, the National Tape Recorder Administration and the Bureau of Cheap Calculators are sure to follow. To avoid the backlog of proposals that is bound to accumulate, *Nature* would like to put forward its own modest suggestion now: a Department of Magazine Mailing whose major function could be the issuance of grants to worthy journals whose competitive position is being hampered by postal rate increases. □

Nuclear winter

US plans for studies proliferate

Washington

A $50 MILLION five-year national research plan for studying "nuclear winter" — possible global cooling following nuclear war — has been drawn up by the National Oceanic and Atmospheric Administration (NOAA). A final draft is now being circulated to an inter-agency review committee before being sent to the White House's Office of Science and Technology Policy (OSTP) by the end of October.

The study plan has been drawn up at OSTP's request by a group headed by Alan Hecht, director of NOAA's National Climate Program Office. It seeks to reduce the principal uncertainties associated with nuclear winter by co-ordinated research in several different areas. The $50 million price tag corresponds to one of several options put forward by NOAA: if the Office of Management and Budget accepts all the study proposals, the cost could be considerably higher. The nominal five years' duration could be extended as necessary.

The proposed study places the highest priority on understanding source inputs of smoke into the atmosphere. Laboratory and field experiments with different fuels would be performed to gain information about the size distribution of smoke particles and their optical properties. Other studies would be designed to investigate how the results from small-scale experiments can be scaled up, first to room size, then to building size and finally to large areas. Ultimately, there would be field experiments entailing managed forest fires instrumented to measure the composition of smoke below, within and above clouds and what happens at the smoke/cloud interface. Some experiments would use areas of clear-felled vegetation.

Hell, there's a much quicker way to find out!
PENTAGON

The number of managed burns the draft plan says, could be contained by studying natural forest fires provided that it is possible to respond rapidly enough in moving equipment and personnel, but some field experiments are thought inevitable. As well as the experimental work, there would be a strengthened modelling effort focusing on further development of mesoscale and cloud models. Optional extras in the plan include studies of the natural transport of Sahara dust and Arctic haze. Also in the high-cost option is work on the biological impact of global temperature changes.

Already, the Department of Energy and the Defense Nuclear Agency (DNA) are managing theoretical studies of nuclear winter. The DNA programme has been allocated $1.5 million in this financial year and will be increased next year; it will be integrated into the national study if and when that is accepted, when DNA may manage some of the work. But, according to Dr C. Gillespie of DNA, the agency's own work is well under way and will not wait for the national plan. DNA concentrates on the chemistry of smoke and on developing modified three-dimensional global climatic models suitable for nuclear winter studies. It also examines likely explosion scenarios and sponsors policy research. All the scientific work, like that in the national programme, will be published in the open literature. Gillespie says the only thing clear so far is that the problems are extremely complex.

Academic scientists who have helped plan this study are pleased by the "unusually good co-operation" and the "non-combative attitude" of government officials from all departments. One commented that nuclear winter is a rare example of an area where disagreements between scientists are noisier than those between bureaucrats. But he fears that the administration may seek to use the scientific uncertainties as an excuse to respond only by commissioning research.

Whatever the political complexion of the administration after November's presidential election, a request for some $50 million of new money over five years will need some justifying. The approval of the President's science adviser (Dr George Keyworth) will be but the first step.

Meanwhile, Congress's Office of Technology Assessment (OTA) is also likely shortly to announce studies connected to nuclear winter. Three broad possibilities are being discussed: a general assessment of what is known about the long-term effects of nuclear war, a survey of all current research relevant to nuclear winter (both in the executive branch and in private institutions) and a more critical study aimed at identifying those areas where further work would be most effective. OTA is unlikely to involve itself in basic research, but feels it does have a role to play in reviewing the efforts of others.

Tim Beardsley

Netherlands budget

Under-the-counter support

THE Netherlands Government budget for 1985, announced last week, contains a few grains of hope for Dutch scientists — and there may be more to come. Science minister Willem Deetman, while broadly protecting the budgets of the national research council (ZWO) and academy of sciences (KNAW), has offered them a little more (just one per cent) to pay for new positions (such as predoctoral and postdoctoral fellowships). Meanwhile, he has continued to tighten the noose on the universities, once considered the best-funded in the world. But, it is said in circles close to the government, he is seeking extra funds to pay for the reinstrumentation of laboratories. But why is he doing this outside the budget, who will benefit from it, and by how much? All these questions are matters for speculation.

At ZWO, the small but respected council for basic science, the budget always contains a few per cent extra for re-equipment, but the sum has been too small "for a number of years", says its director, Professor Robert van Lieshout. In the budget this year, ZWO receives Dfl 15 million (£3.5 million) in this category, around seven per cent of the working budget "but we need ten per cent", says van Lieshout.

Nevertheless van Lieshout is relieved at least to find his net budget uncut. The universities had suffered what they claim to be the maximum possible reductions in recent years, while the research council had been left unscathed; and the Dutch budget minister was demanding more cuts all round. "It's our turn next", said van Lieshout before the budget — but his fears were unfounded.

Moreover, through a budget decision which affects many national institutions, ZWO (and KNAW) find they have a one per cent budget increase to pay for new posts. In ZWO at least, these will be used to provide a few more much-needed postgraduate and postdoctoral fellowships. The Huyghens programme, providing fellowships for high-flyers (20 last year, the first year of the programme), will also be continued by "scraping off" another one per cent of the total ZWO budget. This year, that will pay for around 16 fellowships — although it has been estimated that perhaps another 100 are necessary to maintain the health of science in the Netherlands.

Robert Walgate

Publication controls

State Department raises hackles

Washington

UNIVERSITIES in the United States are mulling over a new threat to freedom of scientific communication, this time from the Department of State. Recent proposed regulations would restrict the export of technical data "directly relevant" to defence. But there is concern that the regulations could be used indiscriminately to curtail export of any general mathematical or engineering knowledge with possible military applications.

The new proposals are to revise the International Traffic in Arms Regulations (ITAR), which have in the past been used to restrict export of information, although less frequently than the Department of Commerce's export regulations (see *Nature* 20 September, p. 195). The arms control regulations are supposed to apply only to military equipment and data. But while much of the research work covered under ITAR is in any event classified, this need not be so. Thus information "directly relevant" to design, development or operation of defence articles is covered.

However, the progress of the new proposals will be rough. The Department of Defense is piqued that some of its own comments on a 1980 draft of the regulations have been excluded from the text, and is preparing a "statement of non-concurrence". This will ensure that the State Department will at the very least have to work hard to justify its proposals, and another draft may be necessary.

Meanwhile, the Office of Science and Technology Policy (OSTP) at the White House is recruiting prominent scientists and industrialists to form an advisory group on the controls on technical data administered by the Department of Commerce. Its job will be to validate and add political clout to proposals drawn up over the summer by an inter-agency working group under Andrew Pettifor of OSTP, which has rejected an earlier suggestion by the Department of Commerce that the existing general export licence for fundamental research should be removed. Fundamental research is defined as anything done on a university campus, and this group says that fundamental research, together with information in the open literature or mentioned at an open conference, should be freely exportable. Details will be circulated for discussion in a few weeks' time.

So far, the Department of Defense, which was represented in Pettifor's group, appears to be bending over backwards to placate academics. Its new declared policy is that fundamental research should be controlled only through national security classification, in marked contrast to its position earlier this year, when its proposals to introduce a new category of "sensitive" research caused widespread protests from universities.

The Pentagon will early next month be publishing a list of "critical technical data" that it wants to see protected. But the new national policy, as it has become known, still has several hurdles to overcome. The proposals of Pettifor's group, which are supposed to provide the nuts and bolts of the new policy, will have to be reviewed both by the White House and by the National Security Council. Any factions in the Pentagon wanting to kill the proposals will still have the opportunity to do so. **Tim Beardsley**

In vitro fertilization

Surrogacy ban by Victoria state

Canberra

THE Victorian state government intends to ban payments for surrogate motherhood and to make surrogacy contracts unenforceable in court following the public release earlier this month of the final report of the committee set up to consider the "social, ethical and legal" issues arising from *in vitro* fertilization (IVF), headed by Victoria Law Reform Commissioner, Professor Louis Waller.

Delivered to the government in August, the report concentrates on the disposition of embryos produced by IVF procedures and should form the basis of widespread discussion throughout Australia. But it approves the techniques which produced the world's first freeze-thaw embryo baby in Melbourne on 28 March this year.

Seven of the nine committee members recommended that the freezing and storage of embryos be permitted to continue, although these procedures should only be undertaken in those hospitals with IVF programmes already approved by the Minister of Health. The hospital itself will not determine the disposition of stored embryos and large embryo banks will not be permitted. Storage, the report says, should be only for short periods, but where a participating IVF couple needs and consents to long-term storage (during chemotherapy, say), storage consent should be reviewed after five years and then may be renewed. The committee also considered that research and development work on procedures for the hitherto unsuccessful freezing and storage of human ova should be encouraged, partly because success would reduce the need for excess embryos in the first place.

According to the Waller recommendations, an embryo should be stored only with the explicit agreement of the couple supplying the gametes, who will have to choose at the outset the embryo's ultimate disposition. If an extra embryo is stored to insure against implantation failure, the couple must decide whether, in the event of a viable pregnancy, their embryo should be donated to another couple in the IVF programme, made available for research or allowed to warm up and perish — to be "removed from storage", in the words of the report. The committee regards the "removal" procedure as morally equivalent to the withdrawal of life-support systems from a mortally ill person.

The embryo should be "removed" if no agreed ultimate provision is made at the time of storage and if, through mischance, the embryo cannot be transferred as initially planned. This appears to seal the fate of the two "orphaned" Rios embryos at present stored at the Queen Victoria Medical Centre in Melbourne, whose parents died last year leaving no directions for the embryos' disposition (see *Nature* **309**, 738; 1984). The government will nevertheless allow three months for further public discussion before the Rios embryos are removed from storage. The committee took the view that untransferred embryos should not be regarded as possessing rights or claims to inheritance.

Two committee members expressed the belief that human embryos should never be used in research at all. Another two members — both medical researchers — claimed that the creation of embryos purely for research purposes was ethically acceptable. The other five members, including the chairman, judged that it was not.

They decided that embryological research in Victoria should be limited to the excess embryos produced by patients in an approved IVF programme. Like the Warnock committee set up to examine the ethics of IVF in Britain, the Melbourne group recommended that experimentation on the embryo should extend only over the first fourteen days, and that all embryo research should be regularly scrutinized. A standing review and advisory body or the state health commission are suggested as bodies capable of the task. As a matter of urgency the committee said that the suggested new review body should examine the practice of *in vivo* fertilization which is already employed in a least one infertility clinic in the United States and which one of the IVF groups in Victoria had stated it would be ready to employ if authorized to do so. Other matters it should consider are embryo cleavage, embryo surgery and genetic manipulation.

The committee's terms of reference were limited to surrogacy in an IVF context. The view was taken that surrogate motherhood arrangements are actually agreements for the purchase of a child, and therefore unacceptable. Non-IVF surrogacy is to be covered in the intended contract-voiding legislation which will then not be uniform throughout Australia. **Jeffrey Sellar**

Information technology

Future reaches Tokyo early

Tokyo

THE first step towards the creation of the "electronic society" took place in Japan this week with the inauguration of a large-scale model Information Network System (INS) in the Mitaka suburb of Tokyo.

The eventual aims of the INS are grandiose: to provide by around the year 2000 a digital network for the whole of Japan which will integrate telephone, telex, facsimile, teletext, computer data and video transmission systems and enable everything from shopping to business management to be carried out from home. If the network is completed, it will require the staggering investment — at present estimates — of 30 million million yen (US$150,000 million).

The model system is rather more modest — about 2,000 households are involved at a cost of Y20,000 million — but it will allow most of the terminal equipment that may be in every household by next century to be tried out. And this stage of the project is going ahead on time, a sure sign that neither criticisms of the INS concept (see *Nature* **305**, 364; 1983) nor the impending privatization of NTT, the telecommunications monopoly, has so far made much impact on the project's future.

Among pieces of equipment not before offered to the public are those exploring the possibilities for increased visual communication. There will be videophones allowing two (or more) people to meet face-to-face on the video screen and a visual circuit service will allow the remote operation of video cameras. This system would, for example, enable an architect to monitor progress on a construction site by dialling the appropriate camera from his home. A totally new visual device is the sketchphone, a telephone that transmits manuscripts and hand-drawn diagrams exactly as they are written or drawn. At first, sketchphones are to be used by the deaf, giving them their first ever opportunity to make telephone calls, and links are to be provided between the Mitaka municipal welfare office and the homes of children with hearing problems.

Other truly new services come from new methods of handling information rather than from new kinds of terminal equipment. If you need to send out the same message to several people, the new network will make that easy: a central voice accumulation device can be used to register the message and the appropriate telephone numbers. The same facility will also be available for facsimile transmission, enabling the chore of sending out New Year greetings cards to be largely automated. The central store may also be used to leave messages for callers, or as a "mailbox" to accumulate calls to be picked up later. Other central facilities will function more like a library. Subscribers will be able to use a videoresponse system to call up still and moving pictures, or to connect with a pre-programmed motion picture service.

A little more mundane are improvements in existing telecommunications services. Subscribers will have new digital telephones that show the number from which a call is coming, the number being dialled and the call charges. High-speed digital facsimile transmission — including multiple address, mailbox and confidential transmission systems — will be available along with access to the CAPTAIN videotext system. In its digital version, CAPTAIN can offer transmission of still pictures with sound or characters and diagrams with voice instructions for terminal use, as well as devices to turn the picture into hard copy. Thousands of pages of information are already available on everything from chess to weather forecasts.

The real excitement over the next 18 months of the system will come, however, not from contemplating new technology but from seeing whether any really new use can be found for information technology. NTT has selected monitors and information providers in order to put the system to as many practical uses as possible and has also connected the Mitaka network to several businesses in Kasumigaseki, one of Tokyo's main office areas, so that some companies with employees living in Mitaka can try letting them work from home or from a satellite office. Obviously the new high-speed facsimile services and videophones will come into their own here and may eventually make unnecessary big offices in central areas with sky-high rents.

For the ordinary citizen, it is the combination of facsimile with CAPTAIN videotext that is likely to be attractive. In the financial field, for example, where 74 separate companies are going to provide services, it will be possible for all the operations for which one would normally need to go to a bank to be carried out at home — information on stocks, shares, exchange rates, insurance, and securities can be provided and transactions carried out. Another 248 companies will use the equipment to provide services in a whole range of fields. Department stores will be able to show goods and collect orders, computer shops advise on operation of personal computers, rail and transport companies provide their timetables and route maps, tour agents conduct potential visitors on pictorial tours of countries overseas, oil companies advise of the nearest open petrol station and power companies facsimile their bills straight into customers' homes.

The real hope (for INS believers) is that subscribers will fight their way through the deluge of unwanted promotional material to a whole new range of applications for telecommunications services. Critics who have looked at the failure of the United Kingdom's Prestel system (which began operation too far ahead of its time in 1979), as well as other nations' viewdata systems, take a somewhat dimmer view. Although INS offers much more than just viewdata, it may still share Prestel's problem of being too stupid to be really useful. Calling up pages of information on a video screen and searching through them is often the slowest and most expensive way to find a particular piece of information, except for special applications such as listing stock exchange prices. What is needed is a truly helpful database, capable of searching for and displaying information specified by its user. No country has yet made available computing power able to handle tasks of that kind.

Whether the Mitaka model system can supply services that customers really want remains to be seen. Those who are desperate for a peek into the future and cannot wait until the end of the preliminary appraisal in 1986 can, of course, simply call up the computerized fortune-telling service that one of the model system companies is offering. And for those who are baffled or simply feel their vocabulary is inadequate for the twentyfirst century, another company is offering explanations of new high-technology terminology as its main service.

Alun Anderson

Model zoo

Washington

THE disclosure that a Texan coral snake on display for the past two years at Houston Zoo is in fact a rubber model has caused consternation in the zoo world. A local newspaper was tipped off by an observant zoo visitor who noticed the snake had not moved in 9 months.

John McLain, assistant curator of reptiles at the zoo, explains that coral snakes are difficult to keep in captivity and tend in any case to hide in litter. As they are venomous, the zoo wanted to educate the public in their appearance, so after several real coral snakes died, the model was substituted. Says McLain: "Many zoos make do with photographs, and we thought we were going one better. We didn't think we were fooling anyone." A zoo official denied that any of the zoo's other animals were models.

Dr Dale Marcellini, a herpetologist at Washington DC's National Zoo, says he has never before heard of a zoo passing off a rubber model snake as the real thing before. But he is sympathetic to Houston's problems and thinks it "not such a bad idea". However, Mr Bob Wagner, executive director of the American Association of Zoological Parks and Aquariums, said his association could not approve of the practice. He intends to take up the matter with the director of Houston Zoo.

Tim Beardsley

Arms control

More Soviet violations alleged

Washington

AN administration report containing the strongest accusations yet of Soviet violations of arms control agreements may finally be released next week. Hardliners both within the administration and in Congress have been pressing President Reagan for almost a year to turn the document over to Congress. Portions already leaked to the press — presumably by members of Congress who have received briefings from the administration — show it to be a strongly ideological statement that mirrors the view of key administration officials, notably Richard Perle and Fred Ikle of the Department of Defense, that the Soviet Union cannot be trusted to abide by any arms limitations treaties. That view has played a major role in the administration's enthusiasm for its Stars Wars concept of a space-based ICBM (intercontinental ballistic missile) defence.

The report was prepared by the General Advisory Committee (GAC) of the Arms Control and Disarmament Agency, a group of outside experts. Although it is formally a report to the President, both houses of Congress have passed amendments to the defence authorization bill requiring that the report should be transmitted to Congress and the signs now are that the administration will not wait for that bill to be enacted before releasing the report. The visit this week of Soviet foreign minister Andrei Gromyko has apparently delayed an earlier planned release date.

In part, the report echoes the major charges that appeared in an administration report to Congress last January — the construction of a possible ABM (anti-ballistic missile) phased-array radar in Siberia, encryption of ICBM telemetry data, testing of more than one new ICBM and the supposed proxy use of chemical and biological agents in South-East Asia. But the GAC report also chronicles other "breaches" going back to 1958. These include "violations of customary international law" (using booby-trap mines and incendiaries against civilians in Afghanistan) and "breaches of unilateral commitments" (atmospheric testing of nuclear weapons in 1961–62, completing construction of SS-20 launchers between March 1982 and December 1983). One lesser known violation cited is the transit of Soviet aircraft carriers through the Turkish straits, a contravention of the Montreux Convention of 1938.

The GAC report is at its most ideological in six "key findings". The Soviet claim during SALT II negotiations that its "backfire" bomber does not have an intercontinental capability, is, for example, cited as evidence in support of the key finding that the "Soviets use deliberate deception in negotiations". Alleged chemical and biological warfare is evidence that "Soviets sign and ratify arms control treaties that they are planning to violate".

The report's authors present a novel theory to explain alleged Soviet breaches since signing SALT II. Because these violations were "done in a fashion which should have at least caused US suspicion", GAC concludes that "a reasonable interpretation . . . is that they are measures designed to test US intelligence capabilities and US political processes relative to arms control" and perhaps "preparation or cover for more extensive violations".

Arms control proponents in the United States have recently argued that both the United States and the Soviet Union are "hedging" on compliance. In an article published in the Fall 1984 issue of *Foreign Policy*, Michael Krepon; director of the verification project of the Carnegie Endowment, notes that the United States is, for example, building a large phased-array radar in Georgia and Texas that could be seen as violating the ABM treaty, as it can cover two-thirds of the continental United States. (The ABM treaty allows only one ABM radar; other radars must point outward to prove that they are early-warning radar only.) Krepon also cites several major weapons construction proposals advanced by the Reagan Administration that would violate existing treaties, including the dense-pack basing mode for the MX, the Midgetman missile and Star Wars. Krepon argues that these actions by the United States signal a "distinct lack of interest in maintaining SALT limitations".

Stephen Budiansky

Toxic hazards in Britain

NEW safety regulations aimed at protecting British workers from exposure to hazardous chemicals have been proposed by the Health and Safety Commission. The commission, having issued the draft regulations in a consultative document, hopes to elicit comments from interested parties before submitting the proposals to the Secretary of State some time in 1985.

The regulations were prepared by a working party composed of members representing the Confederation of British Industry, the Trades Union Congress and independent experts. They require employers to assess any danger their workers face, to take steps to reduce that danger to an acceptable level and, in addition, to provide safety training, to monitor the health of workers and to keep detailed medical records. These measures clarify and extend the terms of the presently enforced Health and Safety at Work Act 1974, a piece of legislation dubbed by critics as vague and too concerned with a small subset of toxic chemicals (lead, asbestos, etc).

Trades unionists are generally delighted with these proposals but some manufacturers believe they will be costly to implement, making British industry less competitive and, consequently, sacrificing jobs. The Health and Safety Commission believes that employers will be helped by a simpler set of regulations applying to all hazardous substances.

Archaeology

Cheshire's oldest inhabitant?

THE British Museum is about to take delivery of a remarkable archaeological find — the body, preserved in peat, of a 2,500-year-old Iron Age inhabitant. The body, uncovered unexpectedly by peat workers in Cheshire, has been in the mortuary of a London hospital since its excavation last month by archaeologists from the British Museum and the University of Liverpool.

Researchers at Harwell have attached a tentative date of 550 BC to skin samples supplied, though they hope to refine this estimate after careful calibration of the radio-carbon dating procedure. When allowance is made for fluctuations in the atmospheric $^{14}C/^{12}C$ ratio over past millennia, the technique could possibly yield an earlier Bronze Age date for the body.

Dr Ian Stead of the British Museum's Department of Prehistoric and Romano-British Antiquities is to supervise the work on the body. Until the layers of peat are peeled away, the exact state of preservation of the body will not be known. But there are high hopes that, apart from the skin already found, body hair, clothing and jewellery will also be revealed. With luck it may also be possible to inspect the stomach contents.

This is the first such find in Britain, though similarly preserved bodies have been discovered in Jutland, Denmark. The Danish remains showed signs of violent sacrificial deaths and have ranged in age from 840 BC, the end of the Bronze Age, to as late as AD 95.

Dr Stead believes that, because preservation techniques have become increasingly sophisticated in recent years, the British find could prove the most important yet. The last Jutland body came to light in 1952 and its condition has deteriorated over the years. The British Museum intends to use the more effective technique of freeze-drying. The museum hopes to have its body on display to the public, curled in its original fetal position, within two years.

UN biotechnology

Green light for twin lab

THE plan to found a biotechnology organization on behalf of developing countries, masterminded during the past two years by the United Nations Industrial Development Organization (UNIDO), moved one notch ahead last week. The preparatory committee of the International Centre for Genetic Engineering and Biotechnology, meeting in Vienna, heard for the first time what funds the two host countries, India and Italy, are willing to commit. The plan now is that a project leader and a scientific committee should be identified by the committee's next meeting in December.

Opinions are divided about the pace of events beyond that. The two years already spent on the discussion of the project are not thought excessive by the yardsticks of international diplomacy, and because the end-product will be a free-standing international organization to which the 33 member states will be bound by a convention with the legal force of a treaty.

In many cases, the project became tangible only at the beginning of this year, with the decision that the new centre would have two components, one in Italy (Trieste) and one in India (Delhi).

The funds now allocated by the two host governments are substantial but far from sufficient to keep the project going. The Government of India last week offered $5 million towards the cost of the first five years' work at the Delhi site, supplemented by an offer of $8.2 million from the Italian Government, which has also promised $4 million and 13,000 million lire towards the cost of five years' work at Trieste.

The two governments will also contribute towards the cost of equipment (Rs 15 million and 58 million lire for India and Italy respectively). India plans to spend Rs 72 million on land and buildings near Delhi, while Italy will provide a building at Trieste at a token rental.

These bids will demonstrate the seriousness of the two hosts and also serve to encourage the others, as at a charity auction. Whether the other potential contributors will arrive at Vienna with enough promissory notes is, however, less certain. Some will wish to know what people are chosen in the next three months, others the colour of their fellow-members' money, while doubts persist about the decision to split the centre into two components.

A further difficulty is that the centre is planned to be the hub of an international network of "associated centres" that will be nationally located so as to assist with training and exploitation. The obvious danger is that member governments will prefer to commit what funds they can afford to the development at home.

There are also further decisions to be made about the division of work between Delhi and Trieste. The Indian centre will be concerned with developments in agriculture and human health, the Italian with the application of biotechnology in the chemical industry, energy and the like. But where (and how) the dividing line will be drawn is still to be decided in detail. □

Badgers at bay

THE conflict between British farmers and wildlife interests over the badger as a source of bovine tuberculosis will persist, last week's report on the subject from the Ministry of Agriculture, Fisheries and Food (MAFF) notwithstanding. The issue is contentious because the badger is one of the largest native mammals surviving in southern Britain and because wildlife interests dispute the reality of the connection between badgers and bovine tuberculosis. Under present policy, badgers are protected under the Badger Act except in areas (mostly in the south-west) where infection by *Mycobacterium bovis* and badgers coexist, as recommended by Lord Zuckerman in 1980.

The latest report on *Bovine Tuberculosis in Badgers*, the eighth to be published, extends the study of captured badgers up to the end of 1983. It says that 13 per cent of 6,000 carcasses examined at MAFF laboratories between 1971 and 1983 show traces of infection, a higher rate of incidence than in any other common British animal.

But do badgers communicate the disease to cattle? If so, then it is presumably via faeces. Tests for *M.bovis* in faeces over the same eleven-year period were positive in 3 per cent of cases. The evidence implicating the badger population as a reservoir for *M.bovis* remains circumstantial and rests on the coincidence of outbreaks of bovine tuberculosis with concentrations of badgers. The case against badgers is strong but not watertight.

There are, unfortunately, no reliable estimates of the size of Britain's badger population. It is unlikely, the World Wildlife Fund believes, that the species is threatened nationally by culling.

Live trapping has now replaced gassing as the chief method of controlling tuberculosis in badgers, in spite of the extra cost. All cattle are tested regularly for bovine tuberculosis and those reacting to the tests are slaughtered. Research into the link between bovine tuberculosis and badgers and control of the disease continues.

Meanwhile, MAFF has announced a further comprehensive review, as recommended by the Zuckerman report, of the problem of badgers and bovine tuberculosis, to be carried out by a three-man team under Professor G.M. Dunnet (University of Aberdeen), and the ministry now promises that the new findings will be made public. Marcus Chown

Sellafield

BNFL on counter-attack

BRITISH Nuclear Fuels Ltd (BNFL), the focus of public criticism during the past year over its waste-disposal indiscretions, has hit back at its critics in its annual report, *Radioactive Discharges and the Monitoring of the Environment, 1983*. The company hopes that data published in the report will draw the debate on its conduct out of the emotional arena and back into the forum of facts. But this seems unlikely while the argument about high leukaemia incidence near BNFL's Sellafield reprocessing plant continues.

BNFL reports that, during 1983, the quantity of liquid waste discharged from its Sellafield site into the Irish Sea was reduced substantially, continuing the trend of recent years. The total beta discharge was cut by 50 per cent compared with the 1982 level and the alpha discharge was down by 30 per cent. These reductions were achieved despite the contamination of a 15-mile stretch of the Cumbrian coastline, near Sellafield, in 1983 after the accidental transfer of plant washings to a sea tank on site, for which the company is now to be prosecuted. BNFL says that the total radioactivity released as a consequence of this error was negligible, amounting, over an eight-month period, to less than one-tenth of a curie (1 curie $= 3.7 \times 10^{10}$ disintegrations per second). This is to be compared with Sellafield's routine beta discharge in 1983 of 67,000 curie.

BNFL concedes that the contaminated beaches seriously damaged public confidence in the company. To restore that confidence, it is to step up its research efforts to cut liquid discharges to "essentially zero". £190 million is already earmarked for this purpose which will, of course, require an alternative disposal route, most probably to a land site. The company stresses, though, that it now operates well within the government's limits for the dumping of liquid waste.

BNFL has continued its programme of monitoring the environment during 1983. Shellfish eaters near the Sellafield plant have been identified as potentially at risk from radioactive contamination, but tests have verified that their exposure amounts to about one half of the annual limit recommended for members of the public by the International Commission on Radiological Protection (ICRP). According to the report, no other group in the vicinity of any other BNFL installation receives an annual dose even close to this level. These findings are confirmed by an independent study carried out by the Directorate of Fisheries Research of the Ministry of Agriculture, Fisheries and Food (*Radioactivity in Surface and Coastal Waters of the British Isles, 1982*).

Marcus Chown

French research

Pragmatism back in fashion

Paris

DURING the past year of economic crisis, the smile on the official portrait of President François Mitterrand has cast a rather baleful air over government offices. But now that smile is visibly brightening. Mitterrand's new boy, 38-year-old Prime Minister Laurent Fabius, is turning France from socialism to social democracy. Mitterrand looks happier with the new tag, and science may benefit as well.

Fabius's minister of research, M. Hubert Curien, is a technocrat, not a politician, and will not let ideology get in his way. Asked by a newspaper last week to choose his *leitmotif*, he replied "to choose and to act". This may sound banal, but Curien means it. And there is no time to hesitate. General elections are due in 1986, and the electorate has lost its taste for the *Partie Socialiste*. The President needs results.

While the French plan — to base economic growth on research — has life in it yet, the rose-tinted spectacles are gone. There is a new sense of realism, for example, on the French policies on the new technologies, in the past always suspect because they were so centralist (despite efforts to the contrary).

French centralism works beautifully in projects which require the mobilization of France like an army, as Napoleon knew. Thus the French have built the TGV (high speed train), conquered space (with Ariane) and introduced nuclear power (half French electricity is nuclear, and the proportion is rising). The recipe has not worked as well for the multifarious worlds of biotechnology and the microchip. Central projects in biotechnology and electronics launched two years ago have run into the sand.

The big surprise is that technocratic centralist France now admits this. The Prime Minister is now being told influentially that these projects must now be decentralized, made more responsive and various. One lesson learned is that while it may be logical for the Institut Pasteur to have just one company — Institut Pasteur Production — effectively controlling applications of Pasteur research, and for the medical research council INSERM to have a similar body controlling applications of monoclonals (Immunotech), commercial and practical realities make such unique relationships inefficient. So change may be expected there, and in many other places where centralism and "logic" have prevailed.

It helps that Curien has room in which to move. His ministry (research and technology) is rid of the short-term problems of heavy industry, which had begun to dominate the old ministry of industry and research in Fabius's time. But useful links between the industry and research administrations have been retained. Curien's budget has also sensibly increased, and there is a prospect of his having more direct power over the budget of a number of organizations (such as the council of agricultural research, INRA), previously only influenced by the ministry.

One immediate task for Curien's ministry is to prepare the budget for 1986, the first year beyond the 1982–85 "law for research" defined by the first socialist science minister, M. Jean-Pierre Chevènement. That could be important. The law as it stands ties political hands. Curien may wish to try something new, such as abandoning the *programmes mobilisateurs* which centralized policy in, for example, biotechnology and electronics.

Another hopeful sign is that French science has loosened up over the past two years. People are more aware of the outside world and more willing to change where change is needed. Even links between research and industry have improved — from a very low base. According to Philippe Lazar, director-general of the medical research council INSERM, "there's been a real shift in the ideology" both in industry and research.

So Mitterrand's new government has brought a sense of hope. But the Fabius honeymoon will soon be over. Then the marriage must begin.

Robert Walgate

UK biotechnology

Advertisement sails near wind

AN advertisement by the biotechnology group Porton International that appeared in *Nature* on 30 August (and in the US journals *Science* and *Bio/Technology*) appears to have caused a flurry of confusion, even discontent, about the relationship between the company and the Centre for Applied Microbiological Research (CAMR) at Porton, the British government laboratory converted from defence to civil purposes five years ago.

Other commercial companies are offended that the advertisement may have been taken to imply that CAMR is either a subsidiary of Porton International or that it may have an exclusive commercial relationship with Porton International. The Public Health Laboratory Service, whose chief function is to provide pathology services and research for British health services, says it wishes to "make it quite clear" that CAMR is "in no sense a subsidiary company of the advertiser".

Even before the transfer of CAMR from the British Ministry of Defence to the Public Health Service Laboratories, CAMR had been keenly interested in the commercial exploitation of some of its projects, notably that for the production of asparaginase used in cancer chemotherapy. Part of the case for not closing the laboratory five years ago was the argument that the British public investment in biotechnology required a laboratory with Porton's experience in microbiology.

The advertisement has given offence because CAMR is described as a component of several of the company's "ten divisions", in which connection it is listed together with operating subsidiaries of Porton International, and because of the use of an aerial photograph of the CAMR laboratory block and another of a new building as "the new production centre at CAMR, Porton". Complainants say that the achievement gives casual readers the impression that the facilities at Porton are the property of Porton International and not the British Government. The advertisement does, however, say (on the same page) that Porton International "has the largest commitment of any company to research and development at CAMR", implying that the relationship between the two organizations is not exclusive.

Porton International, described in the advertisement as an "independent private group whose shareholders include world leading pension funds and institutional investors", is a company recently created by Wesley Haydon-Baillie with funds from UK and overseas financial institutions. Its British subsidiaries include the well-established company LH Fermentation. Porton International also has a licensing agreement on the herpes vaccine developed jointly at the University of Birmingham and CAMR, now in clinical trials, while other collaborative ventures are in the process of being negotiated.

The laboratory staff's views of the advertisement are mixed. Some point out that Porton International is the largest single customer for CAMR's research services, in which role it supports several members of the laboratory's staff and also has a lien on a proportion of the potential output of the production plant. Others, however, still resent the company's use of the name "Porton", first registered for commercial use in 1982.

By some accounts, the appearance of the advertisement may have complicated a series of negotiations which have been under way for some time between the Department of Health and a number of British companies with interests in biotechnology, the chief effect of which would be to convert part of CAMR into a research facility for a commercial consortium. This is not inconsistent with the insistence of the Public Health Laboratory Service that CAMR is independent and "that there is every intention that this independence should continue".

John Maddox

Florida citrus

Burning bugs sole defence

Washington

WITH the discovery last week that citrus canker has spread to four new nurseries in Florida, drastic measures to halt its further spread seem unavoidable. State agricultural officials have been granted authority to burn all infected trees as well as all trees standing within 125 feet of any tree originating from one of the five infected nurseries. The nursery where the outbreak was first discovered, and which appears to be the source of the other outbreaks, has shipped 89,000 trees since January this year.

Meanwhile, a handful of scientists in Florida and at the Department of Agriculture (USDA) Beltsville laboratory, as well as its Animal and Plant Health Inspection Service, are struggling to discover where the infection originated and whether controls more sophisticated than burning can be effective. According to Dr Ed Civerolo of Beltsville, who has studied citrus canker since 1978, the bacterium responsible for the Florida outbreak appears to differ from those found in recent years in Mexico, Brazil, Argentina and Japan. Although of the same species (*Xanthomonas campestris citri)*, the bacteria in different areas exhibit different host preferences and virulence. The Florida bug is the most virulent, attacking all citrus species. Significantly, the Florida strain does not resemble the Mexican, which is a relatively mild version and which is specific for key lines. Initial studies by Civerolo over the past few weeks indicate that unlike all other known strains, the Florida version contains no plasmids; it also differs in fatty-acid composition and is serologically distinct.

Citrus canker last appeared in the United States in 1912, when it took 15 years to eradicate. On that occasion, the bacteria were carried on rootstocks imported from Japan.

Surprisingly, burning is still the only effective control measure. Bactericides have been singularly ineffective in fighting bacterial plant diseases of all sorts; under favourable environmental conditions (such as a hot moist climate and extensive acreages of suitable hosts), the bacteria simply grow faster than they can be wiped out. Bacterial resistance to antibiotics is also a problem.

An epidemiological study is now beginning to trace the source of the latest outbreak. Contaminated growing stock is the most likely source. Although the United States forbids importation of growing stock except for research (and then only under strict quarantine which requires isolation and propagation in greenhouses for a matter of years), USDA officials say they believe a certain amount of stock circumvents the safeguards, entering the country illegally. Since the bacteria infect stems, leaves and fruits, it is also possible that they were carried in on contaminated fruit or other debris that somehow came in contact with the Florida trees.

The United States has maintained quarantines against the importation of citrus fruits from other countries where the disease is present. So far, none has reciprocated following the Florida outbreak. The US Government has, however, imposed an interstate quarantine; only fruits from inspected groves will be permitted out of Florida, and then only if they are dipped in a chlorine disinfectant and if the destination is a non-citrus-producing area. (Texas and California are the other major citrus-growing states.) The most immediate economic effect on the Florida growers, however, is likely to be that of the eradication programme. Compensation is not being provided to those whose trees are destroyed, and the US Secretary of Agriculture could order compensation only after declaring an "extraordinary emergency", which has never been done for a plant disease.

If the infection should become established in Florida, that would not mean the end of the Florida citrus groves. The immediate consequence of infection is disfiguration of the fruits by raised brown spots and a decline in vigour of the trees and of their yield. But in severe cases, substantial defoliation and premature fruit drop can occur, and the trees may ultimately die.

Stephen Budiansky

Danube environment

Hungarians seek outside support

Budapest

THE Hungarian Government has an environmental battle on its hands over a controversial hydroelectric scheme which, among other things, would entail the diversion of the Danube. Ironically, while the fourth environmental engineering exhibition was being mounted last week, an unofficial Hungarian group called the "Danube Circle" began soliciting Austrian support for its opposition to the project.

The project, which includes the diversion of the major part of the Danube waters through a canal to a power station at Gabcikovo in Czechoslovakia, and the construction of a dam at Nagymaros which would flood the most scenic stretch of the Danube, has been undertaken jointly by Czechoslovakia and Hungary. Hungarian environmentalists fear that the dam would cause irreversible damage to the water table of northern Hungary, endangering the water supply of up to 8 million people, and could lead to the disappearance of many species of flora and fauna from the river and its banks. The agreement between the two governments was signed in 1977, but was based on plans drawn up much earlier, when the long-term environmental consequences were little understood.

Between 1978 and 1983 there was considerable criticism of the scheme in the Hungarian media. Political considerations made it impossible for the Kadar government to withdraw unilaterally from the scheme; nevertheless, in 1981, all work on the Hungarian side stopped, allegedly due to lack of funds. Last autumn, moreover, while signing a new agreement reiterating Hungarian commitment to the scheme, the Kadar government managed to reschedule the completion date from 1990 to 1994.

At this point, the Danube Circle launched a petition, signed not only by Hungary's small community of "dissidents" but also by a number of leading environmentalists, some of whom had actually worked on the official survey of the hazards.

The protesters were particularly irate that the Hungarian public had never been allowed to express an opinion about the project, and that, furthermore, no proper survey had been made to establish the global effects and risk factors. The government responded by clamping down on all media discussion of the project — a somewhat unusual response for Hungary, which in general prefers to stimulate public discussion of environmental issues, so as to bring fears into the open and then allay them with a concerted press campaign.

Upstream, meanwhile, an Austrian proposal to build a similar dam at Hainburg provoked a protest petition with more than 150,000 signatures. Presumably in response to this, the Austrian Government proposed an arrangement by which it would partially finance the construction of the Nagymaros power station in return for a supply of power in the future. But according to the Danube Circle, the whole concept of the scheme, which is to top up electricity supplies at peak hours, is impractical, since the Danube is at its lowest in winter.

It is rumoured in Hungary that the government has had second thoughts on the affair and is trying to find a diplomatically acceptable way of withdrawing. (This view is perhaps substantiated by the fact that the International Danube Commission, based in Budapest, is likewise unwilling to comment on the situation, implying that some kind of negotiations are taking place.) If, however, Mr Kadar has been using the excuse of lack of funds to postpone construction works until such a solution can be established, the Austrian proposal to contribute to the construction costs could prove embarrassing.

Objectivity versus doctrine

SIR — It has been fashionable for scholars on the periphery of science to attack the idea that science can be objective and value-free. This view stems from confusion between different meanings of the word "science" as a highly subjective activity, a methodology that maximizes objectivity and the resulting body of knowledge. Although we have become more aware that unconscious bias is often hard to avoid, the goal of objectivity remains the foundation on which the success of science rests. No less than in Galileo's day, the deliberate introduction of ideological preconceptions into the scientific process undermines its integrity.

I was therefore dismayed that Sir Peter Medawar reviewed *Not in Our Genes*, by Lewontin, Rose, and Kamin, with enthusiasm (*Nature* 19 July, p. 255). Moreover, he even quoted approvingly part of the authors' frank statement of political purpose: "We share a commitment to the prospect of the creation of a more socially just — a socialist — society. And we recognize that a critical science is an integral part of the struggle to create that society, just as we also believe that the social function of much of today's science is to hinder the creation of that society by acting to preserve the interests of the dominant class, gender, and race." Unfortunately, in admiring the goal of a just society, Medawar overlooks the possibility that the authors' commitment to Marxist doctrine would conflict with their commitment to objectivity.

In fact, the authors skilfully distort the views of scientists interested in human behavioural genetics, intelligence testing and sociobiology, condemning research in these areas as worthless rather than as necessarily limited in precision. Indeed, almost no biomedical research could meet their perfectionist standards. Moreover, they project upon their victims a political motivation equal in intensity, but opposite in direction, to their own. They even condemn Kety's classic demonstration of a major role of heredity in schizophrenia, ignoring the fact that genetic studies on this disease are likely to lead, through the reductionist molecular genetics that they decry, to specific chemical therapy.

Historically, this book must be regarded as part of the long campaign of a group from the radical left, called Science for the People, to outlaw the study of human behavioural genetics. While most of the book repeats this group's earlier arguments, there is one major shift. After many years of trying, with little success, to convince the world that genes have little to do with individual differences in behaviour or in potential, Lewontin *et al.* now deny any such naive cultural determinism and adopt the position long held by their opponents: intelligence is the product of gene–environment interactions. But their turnabout seems to be more a matter of strategy than of convinction: note the title of the book, and the statement that J.B.S. Haldane and H.J. Muller "argued (along lines that we would not) that important aspects of human behavior were influenced by genes" (p. 73). Moreover, instead of gracefully seeking an end to the sterile polemics, they claim the high middle ground of interactionism for themselves, and they cast down their opponents with the epithet "biological determinist" repeated (in a familiar political tactic) on virtually every page.

The authors are unusual not only in the righteousness but also in the manners that they bring to scientific controversy. For example, after quoting Louis Agassiz's assertion (in the nineteenth century) that the human sciences can in principle be freed of politics and religion, they add that "The sentiment was echoed in 1975 by yet another Harvard professor and biological determinist, Bernard Davis, who assures us that 'neither religious nor political fervor can command the laws of nature'". Then follows another quotation from Agassiz: "the brain of the negro is that of the imperfect brain of a seven-month infant in the womb of the white".

As a reviewer has noted, this slur, passing three authors and an editor, says much about the intent of the book (see M. Konner, *Natural History*, August 1984, p. 66).

Why does such doctrinaire and ambiguous rhetoric appeal to many thoughtful people, as it has to Medawar? Obvious reasons include the past misuse of genetic theories to support racism, fear that genetic studies of behavioural traits might reveal differences between races and the belief that it is racist even to entertain that possibility. But this belief, however well intentioned, is profoundly illogical: racism is the willingness to have race, rather than individual qualities, determine a person's social treatment. Moreover, modern genetics has made a major contribution to the struggle to overcome this evil. For the intellectual justification of racism has been the ancient assumption that the differences between races are typological — that all the members of one group differ from all the members of another. But in contrast to the naive support of this view by certain geneticists in the past, modern population genetics has utterly destroyed its typological foundation. We now know that the genetic differences between races (except for some physical traits subject to climatic selection) are statistical and overlapping, and so one cannot infer an individual's potential from his race.

Future advances in understanding human diversity could also help us to reach humanitarian goals, by improving our efforts to develop individual potentials. To be sure, since knowledge of genetic differences, like almost any scientific knowledge, could be used for ill as well as for good, it is understandable that some people focus on the immediate danger. But the shift of genetics from typological to populational thinking encourages confidence that its further advances can have a constructive social impact.

It is sad to see one with Medawar's eminence, and with his credentials as a writer on the philosophy (and on the manners) of science, lending credibility to this book. He does criticize its attack on reductionists, because he finds that they simply do not exist as described. But he does not question the existence of biological determinists, even though they are equally imaginary among modern biologists. He also approves what he terms the "right-thinking" quality of the book. But "right-thinking" (or orthodoxy) is a dangerous concept in matters involving science. If it refers only to the general goal of a just society, or to Medawar's stated belief that the world is in need of change, fine — but if it encompasses or condones political bias in the evaluation of science, it presents a grave challenge.

The extreme positions and the political propaganda presented in *Not in Our Genes* are unlikely to influence the views of many scientists close to the field. Nevertheless, the book may convince lay readers, and it will surely have a distorting influence on the public image of science.

Genes-on

SIR — We now have quite a large number of types of gene. It might be sensible to suggest they are all named in the same way, so that they can be instantly recognized, as enzymes are with their "ase". Maximum simplicity and clarity may be achieved if they all ended with "on", with enough on the front end to indicate their function or status. We have already: recon, muton, replicon, codon, cistron, operon, transposon, regulon, exon, intron operon. There must be others I have not thought of.

Recently a new gene with a widely conserved sequence which may control development in a wide range of segmented animals has been announced, how about "onton"? This would go well with a single oncogene being called an oncon.

Other conversions could be: plasmogene into cyton for cytoplasmic genes; palaeogene into palon; neogene into neogon; regulator into represson (distinct from regulon which means something else).

Perhaps a modern geneticist should define all these terms as proper units, so that we may all express ourselves with precision.

Mistreatment of laboratory animals endangers biomedical research

from Christine Stevens

There is now an opportunity for legislators in the United States to rescue medical researchers from themselves.

In the United States, laboratory animals are used in much greater numbers and subjected to far more neglect and mistreatment than elsewhere, in Britain for example. The reason for this is simple: US law does not come to grips with pain prevention. In the absence of an adequate regulatory regime, an all too casual attitude has developed. Pain relief, or indeed any sort of post-operative care, is often omitted in laboratories, test procedures are unnecessarily duplicated and even the minimal standards of care required by current law are routinely ignored. These negligent attitudes are reinforced by a chronically short-staffed and underfunded federal enforcement programme on the one hand and, on the other, an aggressive lobby of commercial animal suppliers whose objective is, simply, to sell as many animals as it can to researchers and testers.

New Bills

An opportunity has now presented itself to bring the federal Animal Welfare Act up to a level roughly comparable with the laws governing the use of laboratory animals in Britain and fourteen European countries. Congress has been presented with two legislative proposals, the Senate with a bill (S.657) introduced by Senator Robert Dole (Republican, Kansas) and the House of Representatives with one (H.R. 5725) introduced by Representative George Brown (Democrat, California), both of which have been endorsed by the American Veterinary Medical Association. Unfortunately, opposition organized largely by the trade association representing laboratory animal breeders has so far prevented these proposals from getting anywhere.

There is no shortage of examples of the current act's deficiencies. The only pain-reducing provision is a deliberately vague phrase included under a general requirement for "adequate veterinary care" which calls for "appropriate use of anaesthetic, analgesic and tranquillizing drugs". Public scrutiny of compliance with this provision is provided only by a requirement that laboratories list the numbers of painful experiments and tests conducted without such drugs, and then note the reason in a one-page annual report.

As a result, compliance even with this vague requirement has been casual in the extreme. The majority of medical schools boldly claim, year after year, that all the pain and distress they cause experimental animals is prevented by pain-killing drugs. (Pharmaceutical houses tend to be more honest in admitting that they inflict suffering; this they usually blame on the testing requirements imposed by the Food and Drug Administration.)

Under the current law, it is entirely up to the researcher to determine whether pain-relieving drugs are necessary. Edward Taub, who received much publicity after the National Institutes of Health (NIH) suspended support for his research on deafferented monkeys, claimed that his superior knowledge made veterinary advice unnecessary. He claimed that no pain-relieving drugs were needed because sensory nerves were cut in the procedure he was using. But Dr William Pryor, the laboratory veterinarian at East Carolina University, testified before a Health and Human Services Department appeals panel to which Taub had taken his case that analogous procedures on humans result in great post-surgical pain, and he recommended an analgesic specifically suited for the purpose.

At the University of California at Berkeley, researchers charged that graduate students conducting major surgery, including the removal of eyes from cats, in Dr Russel DeValois's laboratory, often administered anaesthesia incorrectly. One witness said, "From the high-pitched squealing of the kitten, it was obvious that the animal was experiencing intense pain".

The Dole/Brown proposals would impose the very modest requirement that researchers consult with a veterinarian in the planning of any procedure involving pain to unanaesthetized animals. The bills would also require that post-operative care be provided and that proper staff be available at nights and on weekends. This might do away with the scheduling of surgery at entirely inappropriate times, as happens now. I have seen unconscious post-surgical dogs left in a room with twenty other barking dogs at 3.30 on a Friday afternoon "Been doing some cutting today?" the veterinarian said to a caretaker down the hall. "Yeah", he nodded.

British act

Before giving further examples to illustrate the need for improved legislation in the United States, I should note that about thirty years ago, I went to Britain at the suggestion of my father, Robert Gesell, Chairman of the Physiology Department at the University of Michigan Medical School, to consult those whom he considered the best biomedical scientists to get their views on the British act regulating animal experimentation. I spoke to Sir Alexander Fleming, J.B.S. Haldane and many other distinguished investigators, and visited their animal rooms.

Even though funds were extremely limited at the time (just after the Second World War), I found the animals far better housed and looked after than in most of the American universities I have recently inspected. Fleming's rabbits were fine-looking creatures, at ease in cages big enough for them to take a hop or two and sit up in the classic Easter rabbit pose if they felt so inclined. Haldane's newts lived in large well-furnished aquaria. In the dog laboratories I visited, the dogs occupied good-sized pens — in sharp contrast with the small cages stacked to the ceiling in many US dog rooms of the period, where the cages were commonly hosed with the dogs still inside trying to dodge the stream of water.

No scientist I interviewed during my visit complained of the British Cruelty to Animals Act. Indeed, I was told that it was of much value in bringing home to young research workers their responsibilities to experimental animals. Neither the individual licences nor the pain conditions under which they worked were burdensome. The general attitude was summed up later, when Sir Graham Wilson and Dr Lawrence Abel came to the United States to testify at a Congressional hearing on 30 September 1965. Dr Abel, a former vice-president of the Royal College of Surgeons, said in part: "We do not commit the atrocities which are reported from time to time in some other countries. We do not allow the extravagant cruelty committed by some investigators of stress and shock. We have proved that the desired results can be obtained by less inhumane methods". This testimony was so telling that the subcommittee chairman, to whom a word from NIH was law, decided to suppress it. The second day of the hearing was cancelled, and the hearing record was never published.

I returned from Britain convinced that the British act was a boon to animals, admired by British scientists and altogether most valuable despite its age and the need, in certain respects, for updating.

But on the other side of the Atlantic, there was a violent reaction by groups such as the National Society for Medical Research when a streamlined bill built on the principles of the British act was introduced by 13 leading senators. NIH's public response was less frenetic but equally adamant. NIH even went so far as to withdraw and secrete hundreds of copies of a substantial study it had contracted for because the report clearly showed widespread mistreatment of experimental animals and indicated a need for regulatory legislation.

Blocking tactics

Senator Lister Hill, named after the illustrious British bacteriologist, was NIH's man in the Senate, and he loyally sat on the bill for six years, refusing all attempts to get it to hearings in the committee he chaired. Not until a stolen dalmatian, trucked across state lines by a dealer in laboratory dogs, ignited an unquenchable public interest, did legislation on laboratory animals reach the Senate floor via a different committee. As soon as it did, the vote to protect the animals was unanimous. Unfortunately, the bill (although opposed as fiercely as the better drafted bill based on the British Act) was weak and narrow in its coverage. Amendments passed in 1970 and 1976 finally gave the Secretary of Agriculture authority to include all warm-blooded animals, and required users to report painful experiments and tests conducted without anaesthetic, analgesic or tranquillizing drugs.

Mistreatment of laboratory animals in the United States in some cases involves a failure to provide even basic care, let alone pain-relieving drugs. For example, at the Veterans Administration (VA) Hospital connected with Stanford University Medical School, a medical student working late was startled to find an experimental dog collapsed at the door of his room. He promptly called the VA veterinarian, but she refused to come to treat the obviously suffering animal, so the student took the dog to the veterinarian on duty at the emergency service, who determined that it was past any possible treatment and euthanized the animal. A necropsy showed nothing but hair in the animal's stomach. The festering sores showed no sign of treatment. The hospital's claims that nothing was seriously wrong and that another dog had inflicted the injuries were hopelessly unconvincing.

Refusal to acknowledge error, no matter how grossly evident, appears to be a common weakness among those who neglect and/or mistreat laboratory animals.

The veterinary inspectors of the US Department of Agriculture (USDA) sometimes try to use their limited authority under existing law to require proper procedures. For example, at the University of Chicago, brain surgery was being conducted on squirrel monkeys in an office off a busy corridor. An office table was used as an operating table. Instruments were not properly sterilized. The inspector called for immediate transfer to one of the university's regular operating rooms.

The proliferation of poorly controlled experimentation in dozens of sites on a campus makes USDA's task difficult, and since the financial provision for enforcement of the Animal Welfare Act has never been adequate, it has sometimes been years before every nook and cranny where animals are stowed away has been ferreted out. At the University of California at Berkeley, it took a new inspector to find them all. USDA finally brought a case against the Berkeley campus, charging major violations. The case was recently settled when the university agreed in a "consent decision" to pay a $12,000 fine, establish a training programme for animal handlers and to "cease and desist" from violating the Animal Welfare Act.

The seeming inability of this institution to control its faculty and students is revealing in the light of the thick report of its own specially constituted committee emphasizing that "more diligence on the part of the investigators and better discipline of the caretakers at a minimum of additional costs" would resolve most of the problems. A typical USDA inspection report reads: "Monkeys in room G25 are fed by placing feed in waste pan under floor grill — no feeders present . . . in many rooms a build-up of faeces . . . no regular observation of animals by caretaker under veterinarian's supervision. Some question of DVM [Doctor of Veterinary Medicine] even having access to animal quarters let alone establish an adequate programme of veterinary care."

Reports for all 1,166 Registered Research Facilities in the United States may be obtained under the Freedom of Information Act (FOIA); the Animal Welfare Institute [of which the author is president] has been studying a series of these over the past six months. The reports are astonishing — Harvard, Yale, Johns Hopkins, Vanderbilt, the universities of Utah, Rochester, Pittsburgh, each receiving between $17 and $51 million a year from NIH, all accredited by the American Association for the Accreditation of Laboratory Animal Care, regarded by NIH as an ironclad guarantee of first-class care and treatment of animals, repeatedly violate USDA's minimum standards.

Most frequently recurring are: cages too small for monkeys, dogs and rabbits to make normal postural adjustments, green scum in the water bottles, inadequate ventilation, and just plain filth. These notes on the University of Utah are typical: "Primates have inadequate space . . . filters are pretty well plugged with hair . . . large rabbits [weighing] 9 to 11 pounds have 432 square inches and they should have at least 540 . . . some of the cages are not high enough that rabbits can stand up . . . feed in some feed containers contaminated with urine from top cage." Or from Rochester: "Primates in Room 6-7573B are being kept in cages which have not been sanitized for over 6 weeks." At Pittsburgh: "The [cat] room did not appear to have been cleaned since the last inspection . . . 24 hours for correction." At Harvard a list of 23 different animal rooms housing dogs, cats, guinea pigs, rabbits, gerbils and monkeys used old, rusty, difficult-to-clean cages. The inspector also noted "loose sharp wires" and wrote "it appears sanitation is non-existent while animals are in isolation chambers". One might suppose that correction would be automatic when USDA inspectors write such comments and the institution's attending veterinarian signs off on them. But unless the inspector actually recommends that USDA's General Counsel prepare a case against the institution, the deficiencies frequently drag on, as documented in the Animal Welfare Institute's files.

The USDA inspectors urgently need the increased authority that the Dole and Brown bills would give them, and they need the assistance which institutional committees under this legislation would provide. Key provisions include the appointment of a committee member not employed by the institution "responsible for representing community concerns regarding the welfare of animal subjects", and the requirement that the committee make semi-annual inspections of "all animal study areas and facilities". In addition institutions would be required to inform their employees to report violations of the law to the institutional committee so that prompt corrective action can be taken. Employees would be protected from discrimination against them which many fear at present if they request better treatment of animals.

The basic purpose of the Dole and Brown bills is to prevent needless suffering before it occurs. By putting all personnel on notice that they are not to turn a blind eye to such suffering, the observant and compassionate would occupy the position now frequently usurped by the callous and domineering. All too often, when I visit laboratories I hear the words, "but don't say I told you". This is absurd when the heads of institutions urgently need to know about mistreatment of animals. If they do not know and thus cannot take effective corrective action, they are increasingly likely to find themselves in the embarrassing position that scandals nobody dared to tell them about are publicly revealed. The consequence of that will be increasing erosion of public faith in institutions supported by the tax payers.

Prevention of needless suffering would also be advanced by the provisions of the Dole/Brown bills that aim to eliminate the wasteful duplication of animal experiments and tests. Unintended duplication of government tests was estimated in 1981, by the head of the Interagency Regulatory Liaison Group, to have wasted thousands of millions of tax dollars, yet there is nothing in the Animal Welfare Act as it stands to prevent recurrence of this needless use of animals. The Dole/Brown bills would establish an information service, in cooperation with the National Library of Medicine, to prevent such duplication. (Purposeful replication of research would be unaffected.) This service would also handle information on alternatives to animal experimentation and testing.

Enlightened self-interest alone should cause every medical school to back the Dole and Brown bills. Failure to protect an investment of millions of dollars by supporting reasonable legislation is shortsighted. But such is the prejudice against legislation, especially on the part of those who do not read the words but rely on lobbying organizations' generalizations, that the Dole and Brown bills are still widely resisted. Organizations that fought the 1966 Laboratory Animal Welfare Act with almost hysterical intensity now, having become accustomed to it, join in testimony before Congress to increase support for its enforcement. No doubt they will do the same if the pending amendments to improve the law are passed.

But the opposition is stepping up its activities. At least that is the sinister reading of the recent decision by the executive director of the Association for Biomedical Research (ABR) to move to Washington, DC. ABR was founded in 1979 by a small group of animal breeders (including Henry Foster, founder of Charles River Breeding Laboratories, the largest purveyor of laboratory animals in the world) and biomedical researchers who felt a need for "active representation" on legislation affecting the use of animals. The organization includes about 200 institutions, including medical schools, pharmaceutical companies and breeders, who depend on animal research. Anyone who doubts that animal research is big business should examine the case of Charles River, which began as a two-room rat-breeding facility and which was recently acquired by Bausch and Lomb, the optical company, in a stock transfer that netted Foster nearly $38 million, according to press accounts.

The spectacular growth of the industry might be slowed by the Dole/Brown bills' requirement that investigators consider alternatives to animals, and by the information service that the bills would establish to provide facts on "methods which could reduce or replace animal use".

Not surprisingly, ABR has favoured substitute legislation sponsored by Senator Orrin Hatch (Republican, Utah) and Senator Edward Kennedy (Democrat, Massachusetts) that would call on the National Academy of Sciences to conduct an 18-month study of the current use of animals in research. This legislation has already been passed by the House of Representatives, incorporated as part of the NIH authorization bill.

Although ABR says that a study is needed in order to determine whether problems really do exist in the use of research animals, its director, Frankie Trull, offered a possibly more candid explanation of its support for study legislation in a recent talk she gave to faculty, staff and students at the University of Illinois at Chicago Health Sciences Center. Trull told the audience: "Now, we are criticized for being strong proponents of study legislation by animal welfare organizations who say this is a stalling tactic. Well . . . none of us was born yesterday. The fact of the matter is that, in some ways, it is a stalling tactic." And in response to a question from the audience on how to deal with the media, Trull offered this advice: "You don't answer their questions. In other words, they'll say, 'isn't it true that 83 per cent of all animals had pain-killing drugs withheld during experimentation in your facility last year?' By the way, they know all that stuff. God bless the Freedom of Information Act, they know everything about everything. What you do is you say something like, 'In 1983, in our research institution, we were able to develop a breakthrough in Alzheimer's disease.'" Trull warned that unless researchers take the fight seriously, what happened in Britain could happen in the United States. "England has had horrendous problems, historically, with antivivisectionists . . . there is no question in my mind that the English, in fact, really truly do like their animals better than their people."

In calling on her scientific audiences to do battle with "the other side", Ms Trull deliberately fosters confusion between soundly based regulatory legislation and antivivisectionist sentiment. She emphasizes the rash of break-ins by animal rights groups. "The reason I say please clean up your own shops is that the break-ins are inside jobs, every one of them. By inside jobs, I mean that some sincere, genuine animal technician or cage cleaner or whatever, goes to an animal rights rally or reads an article in a magazine and wants to help the other side. Every single one of the break-ins in the 30 or 40 we're aware of involve inside jobs."

A rational response to this would be to enact the appropriate legal escape valve in the Dole/Brown bills so that personnel who observe mistreatment of animals are protected against reprisals when they blow the whistle — and that a local institutional animal care committee exists to receive such complaints, investigate, and order the problem corrected. But such a sensible procedure is anathema to ABR, which thrives on an "us and them" mentality.

Edmund Burke's advice to choose early reform, which he described as "accommodation with a friend", as against late reform or "capitulation to an enemy," is lost on the lobbyists who fight against proper regulation of animal experimentation. Thus the biomedical community, which needs the Dole/Brown bills as much as the animals do, is listening to badly biased advice inspired by vested interests that seek to increase commercial profits on animals, equipment and services.

Pain clause

Most European countries have legislation which addresses pain prevention, often more specifically and strictly than the Dole/Brown bills. The pain conditions in the British act, for example, which have proved workable over more than a century, have spared great pain to large numbers of animals. The proposed bills require assurances that paralytics may not be used without anaesthesia, and pain relief or euthanasia may not be withheld when not scientifically necessary, much milder provisions than those which obtain in Britain.

At present, it is common for animals to be left to die in agony, and no law requires that they be euthanized even when the experiment is over. Nor does current law specify that dogs must be released for exercise outside their cages. The Mayo Clinic is still hosing cages with the dogs inside. Small wonder that contagion is rife among the more than 500 dogs recently viewed by the 13 owners of stolen dogs that Mayo had purchased, despite repeated warnings that many of the dogs they kept buying seemed to be pets. Before the recent scandal broke, Mayo even bought dogs at the laboratory door. Now a sign is posted: "All please note. We no longer purchase dogs from individuals. But we continue to take them as gifts." It was through this unexpected review of Mayo practices that the dehydration of Mayo dogs came to light. Two owners reported that their dogs immediately drank five-quart pails of water on their return home, so intense was their thirst.

It is only natural for people to become angry when the privilege of using laboratory animals is so grossly abused. The US Congress and people generally want the abuses stopped. Neither Congress nor the overwhelming majority of the public want a ban on experimentation. Scientists of good will should recognize this, reject the paranoia sown by lobbyists and join with legislators such as George Brown, a tried and true friend of science, and Senator Dole, whose record on fiscal responsibility has earned him great respect for sound decision making.

"Those who experiment upon animals", Albert Schweitzer wrote, "by surgery and drugs or innoculate them with diseases in order to be able to help mankind by the results of pain, should never quiet their consciences with the conviction that their cruel action may in general have a worthy purpose. In every single instance, they must consider whether it is really necessary to demand of an animal this sacrifice for men. And they must take anxious care that pain be mitigated as far as possible." □

Christine Stevens is President of the Animal Welfare Institute, Washington, DC, 20007, USA.

New ways with solar neutrinos

The discrepancy between predicted and measured neutrinos from the Sun is an embarrassment. Now there are two schemes for improving on past measurements. They deserve serious backing.

MUCH of the present excitement in cosmology rests on the recognition that there must be a close connection between this conceptually esoteric field and high-energy particle physics, the stamping-ground of those who would push experimental measurement to the limit. The result is that people are always speaking in measured tones about the common ground between the very large and the very small.

And there are successes on the record. Astrophysics shows the neighbourhood of a neutron star to be a kind of natural high-energy physics laboratory. The abundance of deuterium relative to hydrogen in the Universe now is almost exactly that calculated from the assumption that the big bang was a time when particles now unstable were predominant in the Universe. And the temperature of the microwave background, 2.7 K, while it is explicable in other ways, is consistent with the view that the whole world was once a high-energy physics free-for-all. So is it not at least a minor scandal that there persists such uncertainty about the Sun's output of neutrinos? Especially when the energies supposedly carried by those particles are measured in MeV, not the GeV which are now the common coinage of the particle physicists?

It is now more than a decade since R. Davis Jr reported the first results with his unique neutrino detector, essentially a huge tank containing 380 cubic metres of tetrachloroethylene buried deep in the Homestake Mine in Colorado. The simple objective was to count the number of chlorine-37 nuclei converted into argon-37 by interaction with a neutrino (and the subsequent loss of a negative electron). The difficulty, ten years ago, was that the rate of conversion and thus the inferred intensity of the neutrino flux was almost an order of magnitude less than expected from what is known of the nuclear reactions in the Sun. All this is now part of the general lore.

Not much has happened since. Or, rather, there has been much talk and speculation but very little experiment. For a time, there was some hope that the discrepancy might be explained away on the basis of the experiments carried out by F. W. Reines at the University of California, Irvine, whose reports of neutrino "oscillations", the quantum mixing together of different types of neutrinos to form the neutrinos of the real world, also bore on the possibility that neutrinos may have a non-zero mass.

But that line of thought has become unfashionable. The experiments are not easy to repeat, and in any case the cosmologists no longer hope to close the Universe with neutrinos of small mass (a fraction of that of the electron). And while the Davis measurement may be reconciled with expectation by using extremes of several astrophysical parameters, leading in particular to a low core temperature, that seems an ungainly way out of the difficulty.

So what is there left to do? Simply elaborating the Davis measurement would be unprofitable, with a rate of conversion of chlorine into argon only barely above the background. J. Bahcall at Princeton has for the past six years been canvassing the use of gallium-71 as a detector isotope. He would buy a stock of several tons of gallium metal, bury in a mine for several years and then sell it back to the original owners. That device would have the virtue of being sensitive to the least energetic and most abundant neutrinos from the Sun, those produced by the direct interaction of protons. One of these fiscal years, the US Congress may look kindly at the project.

Meanwhile Davis (at the Brookhaven National Laboratory) and a group of colleagues scattered over the United States have suggested yet another neutrino detector. The principle is again the same — convert an isotope of one element into an isotope of another by neutrino interaction, making sure that scores or hundreds of atoms of the product can be measured. The new plan is to convert bromine-81 into krypton-81 (again by the absorption of a neutrino and the loss of an electron). But this time, the product is only weakly radioactive (with a half-life of 200,000 years).

In principle, the experiment (if ever carried out) would have the advantage of being neatly complementary to that proposed by Bahcall. Indeed, bromine-81 nuclei would interact only with neutrinos whose energy exceeded the threshold of 470 keV, which implies that they would be converted into krypton nuclei chiefly by neutrinos arising within the Sun from the radioactive decay of boron-7.

The hope that the quantities of krypton-81 produced can be measured will stretch most people's credulity. If the calculations are correct, krypton isotope atoms should accumulate in the 380 cubic metres of the tank (supposed filled with an organic compound of bromine) at a rate of about two a day, or some hundreds every six months. How are such small quantities of a stable isotope to be detected?

Obviously it helps that krypton is a rare gas, essentially insoluble in organic liquids. Indeed, using their tank filled with its organochlorine liquid, Davis and his group have been able to test the feasibility of what they propose. Having a system for the extraction of argon from the tank, they can just as easily isolate krypton. They find that leakage of atmospheric krypton into the system should not be a serious source of whatever krypton-81 might be produced by neutrino conversion. After say a year, their bromine tank might contain 1,000 atoms of artificial krypton-81.

But how to measure such tiny amounts? Perhaps because they are anxious not to discourage potential backers, the authors make light of the difficulties in their account of a simulation they have carried out (G.S. Hurst *et al. Phys.Rev.Lett.* **53**, 1116; 1984).

The technique consists merely of repetitive mass spectroscopy. Atoms of krypton-81 in what is supposed to be a mixture of krypton isotopes are selectively ionized by a suitable laser and then accelerated selectively and embedded in a silicon target. Since the ionization process will not have been entirely selective, the embedded atoms can be recovered by heating (again with a laser) and put through the process a second time. And, if necessary, a third. Finally, the atoms are embedded in a copper/beryllium target.

Whatever the likelihood that the technique will eventually settle the problem of solar neutrinos, it seems certain to be used widely in other connections. What the authors show, however, is that starting with a sample containing 1,000 atoms of krypton-81 and the contamination expected in a neutrino experiment, they should be able to count as few as 300 atoms. Laser improvements already foreseen should reduce the limit to about 100 atoms.

For many people, this would be sufficient. But plainly Davis and his colleagues intend a renewed assault on the measurement of solar neutrinos. Indeed, they talk of the design of their complementary detectors as the first steps in the spectroscopy of solar neutrinos. They should be given a chance to put their scheme to work and save the nexus of cosmology and physics from the embarrassment on its doorstep.

Atmospheric chemistry

Implications of Arctic air pollution

from S.A. Penkett

IN winter, the southward movement of the polar front allows air from polluted regions of the Northern Hemisphere to be transported into the Arctic, giving rise to a phenomenon known as 'Arctic haze'. This can lead to a visibility in this pristine area of the Earth's atmosphere of as low as 5 km. The scientific community has been aware of the phenomenon for several decades but a detailed study has been impeded by the remoteness and inhospitable nature of the region. Recently, a series of 28 papers has been published (*Geophys. Res. Lett.* **5**; 1984), describing experimental data obtained in a three-dimensional coverage of the atmosphere from Alaska to northern Norway. The papers deal with the meteorology that causes the phenomenon, and with many other aspects which have relevance to such topical concerns as the long-range transport of acidity and climatic change caused by anthropogenic activity.

The results mostly come from the Arctic Gas and Aerosol Sampling Program. It involved the use of six aircraft flying over the Arctic, collecting information on the nature and concentration of the particles making up the haze and on the composition of the associated air. The programme was organized by Russell C. Schnell from the University of Colorado. Scientists came from the United States and Europe, with the majority of the Europeans coming from the Norwegian Institute for Air Research. Funds were provided by the National Oceanic and Atmospheric Administration and by the British Petroleum Company. It is an example of the sort of cooperative programme that has to be mounted if air pollution problems of regional or global significance are to be tackled in detail.

Previous studies at ground level had shown that the aerosol consists mainly of fine particles in a relatively narrow size range (0.2 - 0.4 μm). Its major constituent is sulphate, but because of the presence of substantial amounts of black carbon, it has been referred to as a 'combustion' aerosol. The major source areas are Europe and north-west Asia and the intensity is greatest in March and April. The aircraft surveys took place during this period and showed the presence of a complex layered structure, with well defined 'fronts' dividing clean and polluted air. The structural discontinuities are very similar to those found at the boundaries of cirrus clouds, suggesting high thermal stability and lack of turbulence throughout much of the Arctic atmosphere in winter conditions.

The origin of the fine particulate is thought to be anthropogenic but new evidence is presented of the possible volcanic origin of the giant (>2 μm diameter) particles. These are spread uniformly at latitudes from 0.3 km to 5 km and are not correlated with the haze layers.

Much of the sulphate in the haze layers is in the form of sulphuric acid and by contrast with other anthropogenic aerosols collected in urban areas of Europe and the United States, there is very little nitrate. The same is also true of the composition of snow samples collected in Spitzbergen.

The low abundance of nitrate is very intriguing. It could indicate that the aerosol is directly injected from combustion processes in the source regions and, indeed, evidence is presented to show that during the Arctic winter, particulate sulphate is not formed by atmospheric gas-to-particle conversion on any significant scale. (That is perhaps not unexpected because of the almost complete absence of any atmospheric photochemistry in the region during the winter months.) A photochemical process may be possible, however, in the source regions at lower latitudes, in March and April. A thorough chemical study of Arctic air pollution may shed light on acid formation in the atmosphere in general. Specifically, measurements of nitrogen oxides and peroxyacetylnitrate, as well as sulphur dioxide, would define the emission characteristics of the source region and the nature of the chemical reactivity of its atmosphere in early spring and late winter.

The geographical origin of the air carrying the haze components has been investigated in several ways. One is by analysing the distribution of trace metals. High concentrations of elements such as nickel, lead and zinc may be traceable to smelters at particular locations deep inside the Soviet Union.

Another specific source of particulate material was identified in aircraft flights across a fold in the tropopause: volcanic debris was found to be entering the troposphere from the stratosphere in March 1983, presumably from the eruption of El Chichón in 1982. Considerable evidence of the influence of volcanoes on the particulate content of the Arctic atmosphere is stored in ice cores from Greenland. By contrast with the measurements reported for Spitzbergen, the Greenland ice core data suggest the presence of summer maxima in nitrate concentrations. Extensive studies of the composition of the ice in different parts of the Arctic could provide interesting details on the distribution of source areas.

Measurements of many gaseous species, including sulphur dioxide, ozone, halocarbons and hydrocarbons, are reported. Aircraft measurements show rather small fluctuations in the ozone vertical profiles, and no large changes within or outside the haze layers. The sulphur dioxide concentration peaks in phase with the aerosol in March–April. Large seasonal variations in the concentrations of many other gases were found. In winter, the Soviet Union seems to be a particularly abundant source of hydrocarbons, with the result that the concentrations of propane and butane are as high in March on Spitzbergen, as in air close to London in August. If these values are representative of the whole of the Arctic region, huge reservoirs of these gases could be built up during the winter to be consumed by tropospheric chemistry at lower altitudes as meteorological and sunlight conditions allow. This would probably lead to the production of large amounts of ozone in the troposphere of the Northern Hemisphere and may account for some of the interhemispheric asymmetry observed for this important trace gas.

The profusion of measurable trace gases, including five distinct bromine-containing species, and the absence of photochemical change in the Arctic winter, may allow a specific categorization of air mass sources. It is not unlikely that their relative concentrations will act as a 'fingerprint' for a source area as with no change in distribution during transport, the 'fingerprint' will remain intact over air-mass tracks of many thousands of miles. A detailed examination could form the basis of an effective large-scale tracer experiment.

Many papers deal with the climatological consequences of the Arctic haze. The planetary albedo can be changed significantly by modification of light scattering, such that an increase of 2.5 per cent over the oceans and a decrease of 9 per cent over the icecap is predicted. The presence of graphite particles in the haze layers (at concentrations within a factor of 2 of those recorded in some cities in the United States) has a substantial effect on the optical depth of the atmosphere and is predicted to increase the energy absorbed by the Earth–atmosphere system by as much as 5 per cent. The climatic effects of aerosols of this type, injected into the atmosphere as a result of a large-scale nuclear exchange, are of much current interest. Fortunately, the Arctic haze phenomenon is on a much smaller scale, but studying it may provide quantitative data which can be used to test predictions of the temperature changes likely to be experienced in the aftermath of a large-scale nuclear war. □

Malaria

Blood-stage antigens cloned

from K. N. Brown

THE development of DNA cloning and bacterial expression techniques has opened up a new approach to studying the antigenicity of malaria parasite and, perhaps, to developing a malaria vaccine. Five groups[1-5] have recently achieved expression of cloned genes encoding sporozoite and blood-stage proteins of the human malaria parasite (*Plasmodium falciparum*). Intriguingly, four of the antigens contain short repetitive sequences. The significance of these sequences is not known, but they may have a role in generating antigenic diversity and preventing host immunity.

Two papers[1,2] were discussed recently in these columns[6]. Of the others, Coppel *et al.*[3] have cloned an antigen associated with the membrane of infected erythrocytes. Immunoprecipitation and immunoblotting identified the antigen as a 155,000-molecular-weight (155K) acidic protein although some sera also reacted with a 210K polypeptide. The smaller molecule is found predominantly in the immature 'ring'-stage parasites and the 210K antigen in mature parasites. This may indicate a precursor–product relationship, particularly since the mRNA appears to be abundant only in fully mature parasites. Presumably the 155K portion is carried into erythrocytes by invading merozoites. Sequence data show a subunit structure of five repeats encoding Glu-Glu-Asn-Val-Glu-His-Asp-Ala. Immediately C-terminal are repeats of Glu-Glu-Asn-Val codons with Glu-Glu-Val interspersed irregularly. There is so far no evidence that antibody reacting with the membrane antigen of ring-infected cells is protective.

Another gene encoding a repetitive sequence, in this case one of nine amino acids, Glu-Glu-Val-Val-Glu-Glu-Val-Val-Pro, and associated with the membrane of erythrocytes infected with mature parasites, has been isolated by Koenen *et al.*[4] (see page 382 of this issue). Early work showed that erythrocytes infected with mature trophozoites and schizonts had exposed antigens. Two of the antigens on schizont-infected cells have been characterized: an antigentically diverse polypeptide possibly associated with the 'knobs' of *P. falciparum*-infected cells[7] and the phenotypically varying SICA antigen of *P.knowlesi*[8]. Whether the sequence identified by Koenen *et al.* relates to either of these polypeptides, and indeed how these two types of antigen are related, remains to be determined.

Of the cloned antigens of asexual erthrocytic parasites, the only ones known from *in vivo* evidence to have some significance for protective immunity belong to a family of polypeptides occurring in all species of mammalian parasite so far examined and varying in size from 190K to 250K. The effectiveness of protection induced varies greatly with the host–parasite combination used[5,9]. In this issue of *Nature* (page 379), Hall *et al.* report that vaccination of Saimiri monkeys with one member of this family, the *P. falciparum* p190 antigen, provides slight protection[5]. This antigen shows extensive diversity between isolates, although there are common epitopes present on the molecule, and many different serotypes can be isolated from one patient[10]. The antigen, or a processed part of it, is present on the merozoite. Hall *et al.* have cloned what is probably its C-terminal end. The sequence is non-repetitive, but it would be surprising if repetitive sequences did not occur elsewhere in the molecule since merozoites and sporozoites are similar in ultrastructure and in function, both being designed to penetrate cells, and the sporozoite surface antigen has well characterized repeat sequences.

Extensive phenotypic variation during chronic infection has been demonstrated for several surface-exposed parasite antigens, including possibly the 190–250K family. It may well be that variable sequences are inserted into all the exposed antigens of malaria parasites, which would provide a solution to two problems: restriction of numbers to ensure host survival and continued parasite survival for vector transmission. Phenotypic antigenic variability is seen in protozoa other than the malaria parasite. The ciliate *Paramecium* is a classic example of a free-living protozoan which adapts its surface macromolecules to environmental change; the changes are readily detectable serologically and indeed can be triggered by antibody. It seems likely that this immunologically important variation results from a general capacity for genetic rearrangement found throughout the protozoa which is exemplified strikingly in the variant surface glycoprotein genes of *Trypanosoma brucei* and has recently been inferred in other parasites[11-13]. In the case of malaria parasite, some of the diversity detected serologically, whether genotypic or phenotypic, may not necessarily be a response to immune pressure, but rather may reflect the requirement of an obligate parasite to enter and survive in genetically diverse hosts.

If genetic diversity and rearrangement are part and parcel of malaria parasites, what hope is there for a malaria vaccine? Given the epidemiology of malaria it is hardly surprising that with the exception of a few highly-selected laboratory systems, immunization with crude or purified antigen is relatively ineffective. Protection has not so far been achieved with the sporozoite surface antigen — is this a result of antigenic diversity[6], immune evasion by antigen capping or inappropriate vaccination technique? Perhaps immunization with vaccinia virus-containing sporozoite sequences[14] will answer the last question. The requirement for draconian adjuvants and the antigenic diversity of the merozoite surface antigen do not encourage much hope for protective cross-reactivity through common epitopes, although there is preliminary evidence that isolates can be ranked for cross-protective activity. Good immunity to virulent blood-stage infection can, however, be obtained using avirulent K^- *P. falciparum* lines[15] and γ-irradiated non-replicating parasitized cells without adjuvant. These results may indicate that parasite antigen seen in the context of modified erythrocyte is the required immunogen. Could such an immunogen be produced in quantity? Does the report of the insertion of new genetic material into haematopoietic stem cells[16] at last begin to approach the level of technical sophistication which immunization against malaria parasite requires, leading ultimately to *in vitro*-grown erthrocytes derived from precursors containing parasite-antigen-encoding inserts in their DNA?

In order to exploit the developments in the molecular biology, a reliable assay of the protective immunogenicity of and responses elicited by the various forms of malaria parasite immunogens *in vivo* will be essential. This is a difficult problem, however, as protective immunity is rarely complete; for example, around 50 per cent of immune adults in holendemic areas may have parasites detectable in their blood at any one time, and recent or current low-level parasitaemia may be a prerequisite for preventing clinically significant infection. Many attacks of malaria over several years are required to generate clinical immunity, and immunity is in part strain specific. The diversity of malaria parasites and the complexity of the epidemiology also make the interpretation in terms of protective immunity of the new epitope and sequence data on surface antigens extremely speculative at this stage. □

Gene regulation

A step closer to the principles of eukaryotic transcriptional control

from Tim Reudelhuber

IN prokaryotes interaction between the genome and sequence-specific DNA-binding proteins has been shown to play an essential part in the control of gene expression. In eukaryotes such a relationship has been much more difficult to prove although evidence is accumulating that certain transcription factors interact with specific promoter elements (see, for example, refs 1, 2). Furthermore, local perturbation of chromatin structure has often been seen over the 5′-flanking sequences of actively transcribed genes. This 'open' chromatin conformation is typified by regions of greatly increased accessibility to cleavage by endonucleases such as DNase I (DNase I hypersensitive sites). These regions have been attracting increasing attention of late, both because they may mark important control regions for gene activity and because we seem to be on the verge of identifying components involved in their generation and, possibly, their function (for an overview of recent advances see ref. 3). To date, the most common finding has been that DNase I hypersensitive sites are missing in the promoter of 'silent' genes and become apparent in tissues which are either expressing or have the potential to express the gene in question. Two weeks ago, Fritton *et al.*[4] reported in *Nature* an interesting new twist to this now familiar story, for the DNase I hypersensitive sites flanking the chicken lysozyme gene.

In the chicken, the gene encoding lysozyme is expressed constitutively at low levels in mature macrophages, and is expressed at high levels in response to steroid hormones in the oviduct. The gene is not expressed in the embryo or in such tissues as brain, liver, kidney and erythrocytes. Fritton *et al.* found that in all the non-expressing tissues studied, with the exception of erythrocytes, there was only one DNase I hypersensitive site (which I shall refer to as B; the other hypersensitive sites are named A, C–E to simplify discussion) upstream of the startsite of transcription. In erythrocytes no hypersensitive sites were detected. In the constitutively expressing macrophages, sites A, D and E were detected while in the hormone-stimulated oviduct an alternate set of sites, B, C and E, was present; site C disappeared when hormone stimulation was withdrawn. What these data suggest is that it is no longer appropriate to refer to the active chromatin conformation of an expressed gene, since different tissues may manipulate the promoter elements in different ways to either 'turn on' or 'turn off' a transcription unit.

An obvious benefit of such a thorough cataloguing of the hypersensitive sites and their correlation with the transcriptional activity of the gene is that it becomes possible to venture an educated guess as to their function. It is known that active transcriptional enhancer elements are capable of inducing regions of DNase I hypersensitivity[5]. In the mouse mammary tumour virus, where an enhancer has been described whose activity is glucocorticoid dependent, a DNase I hypersensitive site appears transiently over this element only during hormonal stimulation[6]. Since site C in the lysozyme gene behaves in an analogous fashion, this region of the promoter is a good place to search for a similar hormone-modulated enhancer whose activation may explain the surge of lysozyme expression in the oviduct. Using similar logic, site B, which appears in most of the non-expressing tissues (but also in the oviduct), may mark the position of the transcriptional repressor element whose effect is overcome by an interaction at site C in the oviduct. The absence of this site in the non-expressing erythrocyte suggests that the cell may have yet another option at its disposal for suppressing lysozyme gene activity. Finally, sites A and D, seen in the macrophage, could mark the position of an alternative set of control elements capable of achieving low-level constitutive expression of the gene.

Of course, the actual function of all these sites remains to be demonstrated. A crucial question to answer will be whether the 'open' chromatin structure of these regions *per se* is important to their function, or whether the sites are simply 'footprints' generated by the interaction of regulatory proteins with the promoter elements. In other words, are the chromatin rearrangements at the hypersensitive sites a prerequisite to the binding of regulatory transcription factors or a consequence of it? *In vitro* systems in which both DNase I hypersensitivity and regulated transcription can be reconstituted will ultimately answer this question. Recent progress has been made in identifying erythrocyte-specific factors involved in generating a DNase I hypersensitive site in the chicken *β*-globin gene promoter[7] and, in a recent issue of *Nature*, Carl Wu described the *in vitro* reconstitution of factors binding in the hypersensitive region of *Drosophila* heat-shock genes[8]. Such advances should take us a step closer to understanding, in molecular terms, the relationship between chromatin structural rearrangements and the control of gene expression at the transcriptional level. □

Synthetic metals

Polyacetylene and organic superconductors lead the field

from Martin R. Bryce and Munir M. Ahmad

A RECENT conference* on the 'Physics and chemistry of synthetic metals' confirmed the unabated interest of organic chemists, physical chemists and solid-state physicists in this field (see Bryce, M.R. & Murphy, L.C. *Nature* **309**, 119; 1984 for a review). Significant progress in the two central research themes, conducting polymers and conducting single crystals, has been made since the Les Arcs meeting eighteen months ago.

Polyacetylene remains the most popular compound with the physicists. It is becoming increasingly clear that the quality of the material and the precise nature of any impurities are of central importance to a rationalization of solid-state properties. A two-step synthesis of polyacetylene was described in which a prepolymer is prepared and then purified and cast into films or fibres before conversion to the polymer by elimination (W.J. Feast, University of Durham). This method produces polyacetylene of high purity and overcomes some of the crystallinity and morphology difficulties of the original Shirakawa route. Homogeneous dense films of $(CH)_x$ can now be prepared and iodine-doping proceeds rapidly to 20 molar per cent to yield material with a conductivity of 10 $(\Omega\ \mathrm{cm})^{-1}$. By contrast, AsF_6 doping proceeds only to a level of 14 per cent. Optical, infrared, magnetic and transport properties of these doped films are similar to those measured for Shirakawa polyacetylene. The nature of polarons and solitons, their lifetime and charge storage, were considered for the chemically-induced defects in polyacetylene (J. Schrieffer and A. Heeger, University of Santa Barbara).

---

*Held in Abano Terme, Italy, on 17-22 June.

Several novel polymeric aromatics were discussed. Poly(isothianaphthalene), a transparent organic conductor with a band gap of only 1 eV, attracted special attention (F. Wudl, University of Santa Barbara). Other important polymers were a fluorinated analogue of poly(1,6-heptadiyne), which is an intrinsic semiconductor with enhanced oxidative stability; a new phase of poly-peri-naphthalene; soluble substituted polyacetylenes, such as poly(trimethylsilyl)acetylene, which can be desilylated to a controlled degree to produce a copolymer; and polypyrrole and related polymeric aromatic heterocycles.

Theoretically, there is still controversy over the quantum statistics of fractionally-charged excitations. Schrieffer discussed this topic in the light of proposals that quasi particles of fractional charge are responsible for the fractional Hall effect in low-dimensional materials.

Over the last two years, the field of conducting single crystals has deservedly been dominated by salts of tetramethyltetraselenafulvalene (TMTSF) which are superconducting at very low temperatures and seem to possess many unique remarkable properties. The development of more sophisticated and elaborate theories confirms that no consistent interpretation of this class of conductors can be reached unless one-dimensional physics is used as the starting point (D. Jerome, University of Paris-Sud, Orsay). A clearer understanding of the fascinating phase diagrams is emerging, and for (TMTSF)$_2$PF$_6$ evidence for transitions from metallic to spin-density wave state to superconducting state as temperature is lowered at constant pressure was presented (J. Schirber, University of New Mexico, Albuquerque).

Crystalline salts of bis(ethylenedithiolo)-tetrathiafulvalene (BEDT-TTF) present an exciting new class of materials. (BEDT-TTF)$_2$ReO$_4$ is a high-pressure superconductor. S. Parkin (IBM Labs, San José) correlated the absence of superconductivity in the majority of BEDT-TTF salts with their high dimensionality compared with the 2:1 ReO$_4$ salt. Applications of single-particle-band theory to the electronic structure of the TMTSF and BEDT-TTF salts reveal striking similarities between the two families; (BEDT-TTF)$_2$ReO$_4$ has the lowest anisotropy of any known superconducting charge-transfer salt.

It is more than ten years since the archetypal organic metal, tetrathiafulvalene–tetracyano-*p*-quinodimethane (TTF-TCNQ), was first prepared and, notably, at the conference this complex was hardly mentioned. There were few reports of new donors. The elusive tetratellurafulvalene derivatives have now been prepared, however. D. Cowan (Johns Hopkins University) described the synthetic approaches and pointed out that although TSeF is harder to oxidize than TTF, this trend is reversed on passing to TTeF which has an oxidation potential similar to TTF. K. Bechgaard (University of Copenhagen) has synthesized the donor 1,6-dithiopyrene, which forms a complex with TCNQ that, even at ambient pressure, is metallic down to 4 K with no phase transitions.

Electrocrystallization is now a widely-used technique for preparing metallic salts, including radical cation salts of arenes. Intermolecular interactions in salts based on oligomers of poly-*p*-phenylene, containing segments that carry a charge, were considered as structural models for conducting polymers (V. Enkelmann, University of Freiburg).

Linear chain compounds remain a focus for attention. Metallic, as well as semiconducting, metal–dithiolene complexes are known (A. Underhill and K. Carneivo, Universities of Bangor and Copenhagen respectively), and ferromagnetic compounds comprising ferrocinium and TCNQ units have been characterized by structural, magnetic, spectral and transport data (J. Miller, Dupont Labs).

The industrial future of synthetic metals for technology and applied science seems bright and there is increasing industrial support. Polyacetylene, polyaniline and poly-*p*-phenylene can be used in batteries and fuel cells employing aqueous electrolytes (A. MacDiarmid, University of Pennsylvania). (An account of recent work on battery performance of polyacetylene by J.C.W. Chien and J.B. Schlenoff appears on page 362 of this issue of *Nature*.) The organic metals that are capable of undergoing phase transitions under optical radiation are being used in electro-optic devices for communication and storage of data (K. Yoshino, University of Osaka) and the first erasable switching device capable of processing information using a single laser source was described (R. Potember, Johns Hopkins University). Moreover, there is potential for organic rectifiers based on a donor molecule linked via an insulating carbon bridge to an acceptor molecule, although because of synthetic difficulties this goal has not so far been achieved. □

Molecular biology

Messenger RNA pieced together

from H.D. Robertson

In a provocative paper on page 350 of this issue of *Nature*, Campbell, Thornton and Boothroyd provide evidence that a short segment at the start of a messenger RNA (mRNA) molecule from a trypanosome can be found as part of a discrete transcript, separate from the remainder of the mRNA. They suggest that either the two segments of the mRNA are transcribed separately and subsequently joined or the shorter RNA segment acts as a sort of primer for transcription of the longer segment. The concrete demonstration of either of these mechanisms would be unique for a non-viral system and, particularly in the case of the priming mechanism, would have very important implications for our understanding of how mRNA synthesis can be regulated.

The expression of variant surface glycoprotein (VSG) genes in the African trypanosome *Trypanosoma brucei* is of extraordinary interest because it is responsible for the successive waves of trypanosomes with different surface glycoproteins that allow the parasite to persist in the face of successive attacks by its host's immune system. Recent work has shown that the mode of expression of these genes — at both the DNA and RNA levels — may reveal new molecular pathways.

Leaving aside for the present discussion the fact that the VSG genes can also undergo DNA-level rearrangements which are related to their expression, it has become clear that DNA encoding a 35-nucleotide leader sequence (the 'mini-exon') of all VSG mRNAs and that encoding the remainder of VSG mRNAs can be 30 kilobases or more apart. This great separation, found by several groups of investigators including that of P. Borst, coupled with the investigators' inability to find giant mRNA precursor molecules which would be expected in a conventional synthesis/splicing pathway, have led Campbell, Thornton and Boothroyd to seek and characterize smaller transcripts containing the 35-nucleotide 'mini-exon' RNA with the idea that these might somehow become associated with the remainder of the VSG mRNA after their synthesis.

Since the mini-exon RNA itself occurs in many RNAs of various sizes extracted from infected cells, Campbell *et al.* have used sequence information from cloned DNAs containing the mini-exon and its immediately adjacent regions to seek small transcripts. Using restriction fragments of the cloned DNAs together with a synthetic oligonucleotide complementary to a region about 100 bases downstream from the mini-exon DNA sequence, they have applied three standard indirect tests, all of which have independently pointed to the existence of a 137-base RNA species which contains the mini-exon at its 5′ end.

Regulation of gene expression at the level of RNA transcription is a phenomenon more widely known at present in prokaryotes than eukaryotes. In particular, gene regulatory schemes in which a eukaryotic RNA transcribed at one place in the genome is used to mediate RNA synthesis at a second site have been difficult to support with experimental evidence. Except in the case of a few viruses, proposals from the early 1970s invoking the use of a RNA specifically processed from one gene transcript to stimulate transcription at a second genomic site have remained in limbo. One good reason for this state of affairs was the discovery in 1977 of introns in eukaryotic genes, leading to wide acceptance of the existence of an RNA-splicing mechanism to allow the covalent linkage of non-contiguously coded RNA transcripts. Consequently, there seemed little biochemical need for another way to obtain the same result.

Nevertheless, the idea that RNA primers could be cleaved from one RNA molecule and used to stimulate transcription of another remains an attractive hypothesis, supported in recent years by evidence published by R. Krug and his colleagues at the Sloan-Kettering Institute of the use of host-cell RNA primers for influenza virus mRNA synthesis. They could be sure that their data did not reflect a conventional RNA-processing reaction because the primer RNA sequence linked by the 5′ terminus of each influenza virus-encoded mRNA segment was demonstrably of cellular origin. Thus, mRNA molecules originating both *in vivo* and *in vitro* could be synthesized in controlled conditions and the origins of their segments analysed in detail.

Until recently, the search for such events — with their regulatory potential — in eukaryotes has awaited a system of sufficient interest to make worthwhile the extra effort needed to distinguish transcription-level effects from those at the level of conventional RNA processing, and in which it was feasible to analyse in detail the expression of various RNA segments comprising a candidate mRNA molecule.

A pool of small RNA molecules containing the mini-exon sequence, such as the 137-base RNA reported by Campbell *et al.*, is a pre-requisite for all models of discontinuous transcription of the VSG genes although it presence does not prove that discontinuous transcription is occurring. Similar results have recently been obtained by Borst and his co-workers using several trypanosome strains (*EMBO J.*, in the press). The next step is clearly the direct analysis of the RNA precursors to VSG mRNA, particularly those containing the mini-exon sequence. In this way, it should be possible to tell whether the RNA segments are made separately and then joined by some unconventional mechanism; whether RNA-primed transcription is responsible; or whether some combination of these events in an even more exotic process could be taking place in this system. □

Giant tortoises down under

THE present-day animals of Australia are a peculiar bunch, but those that lived one million years ago, in the Pleistocene, were even stranger. There was a giant wombat called *Diprotodon* which was the size of a rhinoceros, and a monster 3-metre-high kangaroo named *Procoptodon*. This trend to large size was also seen in the turtles. The available specimens of the tortoise *Meiolania* have recently been restudied (Gaffney, E.S. *Bull. Am. Mus. nat. Hist.* **175**, 361; 1983) and some important new finds are reported.

Meiolania platyceps was a 2-metre-long tank-like land tortoise that is known from numerous remains found on Lord Howe Island, New South Wales. Its skull was heavy and covered with an outer armour of plates and horns — no doubt so that it could withstand the impact of a giant kangaroo landing on its head. *Meiolania*, like most turtles, had a relatively small braincase, so it probably wasn't very bright. Its shell was huge, and its arms and legs could be pulled in beneath it. One remarkable feature of *Meiolania* is its tail which was long and carried at its end a bony mass made from rings and spikes. Like certain armoured dinosaurs (the ankylosaurs), *Meiolania* could have swung its tail from side to side to deliver a powerful blow to any potential predator.

All the material has been collected from shoreline and soil deposits on Lord Howe Island, and these have been tentatively dated as 100,000 - 120,000 years old. The first *Meiolania* bones may have been collected in 1844, when John Foulis MD visited the island. He later recommended that it be developed as a penal colony, stating that the island could "support a population of 5,000 souls if under control". One wonders what 'control' he had in mind. The island was not developed in that way. Later, Robert D. Fitzgerald visited the island and found turtle bones in 1869. He sent specimens to Sir Richard Owen, the leading British comparative anatomist of his day. Further bones have been collected since then, with recent finds in 1971, 1980 and 1982; most of these went to the Australian Museum, Sydney.

Richard Owen identified the first skull and tail club of *Meiolania* that he saw as that of a giant lizard (1881, 1882) and, later (1886), other remains as those of a large turtle. It was Thomas H. Huxley, a rival of Owen's, who gleefully pointed out that Owen's 'giant lizard' was in fact a turtle (1887). Since then, other British and Australian scientists have identified various *Meiolania* bones, and speculated wildly about the animal's precise taxonomic relationships.

In the new work, Gaffney redescribes the skull in detail, and concludes that *Meiolania* is a cryptodire turtle, related to present-day soft-shell turtles and tortoises.

Meiolania died out, with the giant wombats and kangaroos, some time ago. This may have been caused partly by climatic changes during and after the Ice Ages, or by the arrival of humans in Australia. Giant tortoises still survive, but only just, on the islands of Aldabra and the Galapagós, but these are not close relatives of *Meiolania*. *Meiolania* would have been a tempting food-source for humans because of its large size, although it would not have been easy to kill because of the heavy armour over its head and body. It was probably very slow-moving and dim-witted, however, and an enterprising group of aborigines could have stood on the tortoise's back to avoid the tail-club, and attacked its unprotected neck with blunt instruments. □

Continental area and elevation

from A.G. Smith

WHEN all the continents were clustered together as Pangea, a small part of that supercontinent experienced flooding by the sea. By contrast, a much larger area of the smaller continents created by the break-up of Pangea has undergone periodic flooding during global rises in sea level. Because there is no reason to suppose that similar changes in sea level did not take place when Pangea existed, an important aim of geophysicists has been to explain the different flooding frequencies before and after the break-up.

Analyses of the global topography suggest that continental area is correlated with continental height. From this it follows that Pangea, the largest possible continent, would have had the largest average height, thereby reducing the area available to flooding during a global rise in sea level. Two authors[1,2] have recently reassessed the suggested area–height relationship.

On page 370 of this issue of *Nature*, Wyatt[1] discusses some of its implications. In particular, he suggests that the reduction in shelf area that might be expected to have accompanied the formation of Pangea may have been a casual factor in the late Permian extinctions of shelf organisms. Stanley, however, has cited evidence that geologically recent reductions in shelf areas have had little effect on some shallow-water faunas[3].

In a recent paper Cogley[2] makes a more detailed analysis of continental topography, particularly continental margins, than the analyses by Harrison and others[4,5] on which Wyatt's paper is based. Cogley concludes that modal height — as opposed to average height — is not correlated with continental area.

He cites several areas that are much higher than any height–area relationship based on the major continents would predict, including Arabia and India. The tiny mountainous islands of Corsica and Sardinia in the Mediterranean are also anomalous, though this is not unexpected as they are associated with young mountain-building movements. However, were Madagascar regarded as a distinct continent, it too would be anomalously high. It would seem that the correlation of continental elevation with continental area is not as clear as one might like.

Until one has a working model of what determines the thickness of continental crust and why it should change with area, it is difficult to know whether these exceptions are important. In the case of the oceans, there is an excellent quantitative understanding of the relationship between ocean-floor depth and age[5]. Anomalously shallow ocean floor is simply a place where more molten rock has erupted or been injected into the crust than normal. Why this should have happened is not clear, but at least the unexpected increase in thickness is explained.

In the case of the continents there is no generally accepted working model of what determines the thickness of their crust. A suggested mechanism of continental uplift is the injection of carbon dioxide and water into the lower crust, but the volumes involved are so huge that such an explanation seems unlikely, except on a local scale.

The only plausible cause is physical. Analogy with the oceans suggests that the most probable mechanism is an increase in heat flow. This could cause uplift simply by bringing about the thermal expansion of the continental lithosphere. Furthermore, the heat could effect crystalline phase changes in the rock minerals, inducing significant volume changes without any change in bulk composition. Uplift associated with uprising convection currents would be unlikely to be as much as the hundreds or thousands of metres observed in, for example, southern Africa. But one can speculate that convection might be more vigorous under large continents and deliver more heat, and this might partly explain the correlation between area and height.

How can these problems be resolved? An important approach will be to document precisely the changes in continental structure with time. One of the most promising sources of information is the rock fragments brought up from great depths in diamond pipes. It might be possible to infer a continental lithospheric structure from a suite of fragments from an old pipe that is know to have penetrated a continent when it was near sea level and compare it with a suite from a younger pipe that penetrated that continent when it stood at a much higher level. Southern Africa may hold the key to this approach.

It is ironic that our understanding of the continents on which we live is far less advanced that our understanding of the ocean floor, which we rarely see. Discussion of the implications of the correlation between continental area and elevation will help to point the way to changing this state of affairs. ☐

NATURE

100 years ago

THE Japanese appear to be determined to render themselves, as far as possible, independent of foreign countries. They have, says the *Pharmaceutical Journal*, established in Tokio a factory for the production of pharmaceutical chemicals on a large scale. A company with a capital of about 40,000*l*. has been formed for this purpose. Of this amount the Government has contributed one-half free of interest for twenty years, besides making a free grant of land and erecting the necessary buildings. A similar company is taking up the utilisation of the waste *saké* from the native breweries in the manufacture of alcohol, and the manufacture of bleaching-powder on a large scale has been commenced. Whether with the object of "protecting" the first of these enterprises or not does not appear, but we learn from the same authority that an increased tax has been placed in Japan on imported patent medicines, and the nature of the articles to which this has been extended is stated to have largely affected the import of some chemicals into that country. Santonin, which was at one time much in request among the Japanese, decreased 20,000 ounces in import last year, although the price was lower; on the other hand, the consumption of quinine showed and increase.

From *Nature* **30**, 512, 25 September 1884.

A SEA MONSTER

A FRIEND of mine, Capt. W. Hopkins, of the schooner *Mary Ogilvie*, who has just returned from a voyage all round Australia, has given me the following information, which I forward you for publication, not so much because of its interesting character, but in order that other travellers may throw some light upon the character of the animal, which, if an Octopus, must be of much larger dimensions than those usually met with. On June 15, when in S. lat. 21° 37′ and E. long .13° 49′, about five miles off the Exmouth Gulf on the western coast of the continent, he saw an immense creature which he took to be a species of Octopus. His attention was drawn to it by a perfect cloud of sea birds, and at first he naturally thought it must be a dead carcass. On approaching it, however, he found it was alive and sluggishly disporting itself. In shape it was like a violin, but of immense size, with some six feelers about the greater diameters of the violin. It lay almost flat upon the water, was of a dark gray above and lighter gray below, and was continually elevating one of its feelers, apparently twice the thickness of a man's arm, to a height of from six to eight feet. It appeared to be vomiting, and as the birds were evidently feeding, that accounted for their presence in such numbers. Its size was so great that, had it grasped the vessel, it could easily have capsized it. The captain therefore got out of the way as quickly as possible, and without making definite measurements; but a large whale in the vicinity looked quite diminutive. It is a pity that something more exact as to size is not available, but I think the description is sufficient to convey an idea of the nature of the monster.

Immunology

Receptor gene rearrangement and ontogeny of T lymphocytes

from Miranda Robertson

MANY of the outstanding questions raised by modern cellular immunology converge on the issue of T-lymphocyte ontogeny. T lymphocytes, so called because they mature in the thymus gland, provide both the cytotoxic effector lymphocytes that eliminate virus-infected cells, and the helper and suppressor lymphocytes that regulate the activities of effector cells including the B lymphocytes that produce antibodies. The exact nature of the thymic maturation process, however, has proved very hard to define, and even the definition of the different subsets of T cells is not altogether unambiguous. Both questions are in part questions about antigen recognition by T cells.

All T lymphocytes, unlike B lymphocytes, recognize foreign antigen in the context of surface molecules encoded in the major histocompatibility complex (MHC), the cytotoxic cells focusing on the class I molecules and the regulatory T cells on the class II molecules. Do T cells 'learn' to recognize 'self' MHC molecules in the thymus, and during this process acquire both tolerance to self alone and the potential to react to self plus foreign antigen? How might that maturation be reflected in the expression of the genes encoding the antigen receptors and how might that vary between different subsets to account for their differential responsiveness to class I and class II molecules? Five recent papers[1-5], three of them published in *Nature* this week[2-4], have an important bearing on these issues.

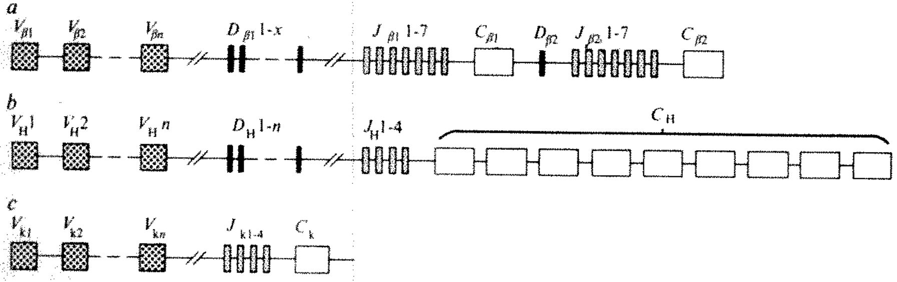

Fig. 1 Gene segments encoding *a*, the β chain of the T-cell antigen receptor; *b*, the heavy chain of immunoglobulin; *c*, the κ light chain of immunoglobulin. Immunoglobulin molecules are made up of four chains, two identical heavy chains that contain a variable antigen-recognition domain and a constant effector domain, and two identical light chains also comprising a variable and a constant region. The variable regions of the light chains, which can be either of two isotypes, known as κ and λ, are assembled from separately-encoded *V* and *J* segments that are brought together by genomic rearrangements during the differentiation of the B lymphocytes that produce antibodies. The final mRNA containing the *VJC* sequence is produced by processing of the primary transcript from the rearranged gene segments. The rearrangements in the heavy-chain gene pool are more complex, in that three separate segments comprise the DNA encoding the variable region: a *V* segment, a *D* segment and a *J* segment which are sequentially rearranged during B-cell ontogeny to produce a continuous *VDJ* DNA sequence. Different combinations of these segments account for much of the diversity of antigen-binding sites in immunoglobulins. The T-cell receptor β chain also contains *D* segments, but is organized differently from that of the immunoglobulin heavy chain in that each of the two constant regions has a set of upstream *D* and *J* segments. Moreover, the two constant regions of the β chain are essentially identical, whereas the immunoglobulin heavy-chain *C* regions are quite different and have different effector functions. The final receptor molecule of the T cell has two chains, known as the α and the β chains; the structure of the α chain is still problematic (see box).

All five papers deal with the genomic rearrangements through which the separate DNA segments encoding the β chain of the T-cell receptor are assembled into a complete gene. Since the β chain is only half of the receptor heterodimer[6], the final answer to the question of antigen recognition will have to await an equivalent analysis of the α-chain DNA. The present position on the α chain (see box on page 306) and the mechanism of antigen recognition will be discussed in more detail in a later article in *News and Views*. I shall here confine myself to the limited but important conclusions that can be drawn from the analysis of β-chain gene organization, and its rearrangement in T lymphocytes of different subsets.

It is now clear that the β-chain DNA shows homology to that of the immunoglobulins not only in sequence but also in general organization: Figure 1 shows how the coding segments compare with immunoglobulin gene segments, and the legend contains a brief recapitulation of how complete molecules are generated from the assembled segments. It was already known the last time this topic was discussed in these columns[7] that the T-cell β chain, like the immunoglobulin heavy chain, is assembled from four separate segments: V_β, D_β, J_β and C_β. Kavaler *et al.*[1] and Siu *et al.*[2] have since cloned genomic D_β segments and are able to demonstrate a significant difference from their immunoglobulin counterparts — not in the coding sequence, though that is of course different — but in the flanking DNA that contains the signals believed to mediate their recombination with the *V* and *J* segments (see Fig. 2). According to the rules that are believed to govern these recombination events (see Fig. 2 legend), neither direct *V–J* joining nor *D–D* joining is allowed in the immunoglobulin heavy-chain gene pool. In the β-chain pool, however, both are possible without violation of the rules. Such flexibility in the assembly of the gene segments might help to compensate for the apparent absence in the β genes of somatic mutations[8] that are known to contribute to the diversity of the immunoglobulins. The structural consequences of the alternative rearrangements in the T-cell pool might however be expected to be more profound than those of scattered point mutations.

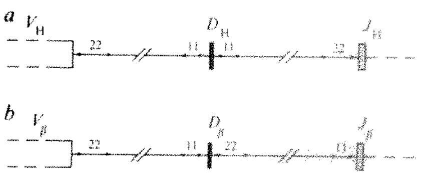

Fig. 2 Recombination signals for the immunoglobulin heavy chain (*a*), and for the T-cell antigen receptor β chain (*b*). The separate DNA segments encoding the variable regions of the immunoglobulin genes are flanked by conserved heptamer and nonamer sequences separated by non-conserved spacer DNA that may be either 11 or 22 nucleotides long, representing either one or two turns of the DNA double helix. These conserved sequences are believed to mediate the genetic recombination by which the separate segments are assembled into the complete coding sequence during B-cell ontogeny, according to a rule known as the 11–22 rule whereby recombination takes place only between a conserved sequence pair separated by an 11-nucleotide spacer and one with a 22-nucleotide spacer. Thus *D–D* or *V–J* joining violates the recombination rules in the heavy-chain gene pool. In the T-cell β-chain gene pool, by contrast, the spacers are so organized that *D–D* and *V–J* joining would be allowed.

So far, however, there is no evidence either for *V–J* or for *D–D* joins. What has emerged from more detailed analyses of the structure and expression of the *D* segments is an entirely unsuspected feature of T-cell ontogeny that has, moreover, been almost simultaneously discovered to have an exact equivalent in B lymphocytes.

In T cells, as in B-cell heavy-chain genes[9], the first joining event is between a *D* and a *J* segment[1]. Siu *et al.* have now discovered that this preliminary joining event results in the production of a *DJC* transcript from a conserved promoter upstream of the *D* segment. The truncated transcripts, which can involve either of the two C_β segments and its associated *D*s and *J*s, are extremely common and indeed account for two of the four cDNA clones originally isolated by Hedrick *et al.*[10]. Siu *et al.* report that the truncated transripts are prevalent in the thymus and are seen very little in peripheral lymph-node T cells[2]. Their prevalence in the thymus could explain why despite the high levels of T-cell receptor RNA in thymocytes[11], Kappler was unable to detect corresponding levels of surface protein (see ref. 7).

Otherwise, however, the importance of the short transcripts is a mystery; though important they must certainly be. First, it is clear from a comparison of mouse and human *D* segments[3] that the *D*-segment promoter is highly conserved, and moreover *DJC* transcripts are highly prevalent in man as well, preliminary data suggesting that they are present in large amounts in thymus and small amounts in periphery; and second, Alt *et al.*[12] have recently shown that equivalent *DJC* transcripts are characteristic of immature B cells in which they are transcribed from a conserved promoter and have also been shown to be translated. No one has been prepared to guess at a possible function for the transcripts, but it must be significant that the *D* segment is the most conserved of all the segments; and it may be significant that both mouse and man have maintained duplicate C_β segments that are almost identical.

Since the near-identity of the $C_{\beta 1}$ and the $C_{\beta 2}$ segments rules out β-chain constant-region isotype as a distinguishing feaure of T-cell subsets, the distinction must be sought elsewhere. One obvious question is whether the same gene pool encodes the β chain of all three major antigen-specific subsets. The original clones were isolated from helper cells. Saito *et al.*[13] have already shown that the same *C* segments are rearranged in cytotoxic cells, and similar analyses have now been extended to other cytotoxic cells and to suppressor cells both in man[4] and in mouse[5]. Hedrick *et al.*[5] have confirmed that the same *C* genes are both rearranged and transcribed in all of six cytotoxic cell lines analysed, and Toyonaga *et al.*[4] find rearrangements of the same *C* sequences in human helper and cytotoxic clones.

The position on suppressor cells is more complex. Toyonaga *et al.* report that their one suppressor clone shows rearrangement of the same C_β sequence; but Hedrick *et al.* find rearrangement in only 2 of 14 suppressor clones: in the remaining 12, C_β segments are deleted, along with very large regions of neighbouring DNA. Moreover, the two rearranged *C* segments lack *V* sequences. The weight of the evidence, then, is that the identified β-chain genes do not participate in antigen-specific suppression of the immune response. The major chromosomal deletions reported by Hedrick *et al.* are unlike anything seen in lymphocyte ontogeny before, and it is not clear what they mean. Saito *et al.*[13] have raised the possibility that if the same C_β segments are expressed in helper and cytotoxic subsets, it remains possible that different V_β pools may be active. This would be consistent with the different MHC-class responsiveness of these two subclasses, and Saito *et al.* point out that the homology between their cytotoxic-cell V_β sequence and the helper V_β sequence of Davis *et al.* is much lower than that between the *V* segments of immunoglobulin genes. It has since turned out, however, that very low homology is characteristic of *V* segments within the helper subset[14]. This discovery, its possible implications for antigen recognition by T cells and the elusive other half of the hererodimer will be the subjects of a second article in *News and Views*. ☐

The Snark was a Boojum, probably

It would be disingenuous, in an article on the T-cell receptor, not to acknowledge the questions that have been widely raised about the true identity of the cDNA clone isolated in the laboratory of Susumu Tonegawa from a cytotoxic T-cell line and credited with encoding the α chain of the receptor (Saito, H. *et al. Nature* **309**, 757; and Winchester, G. *Nature* **309**, 750; 1984).

Doubts were already being voiced at a conference on 'T-cell receptors, genetics, structure and function,' held at the Given Institute in Aspen, Colorado on 6–8 July, within a week of the appearance of the report in *Nature*, on the following grounds. Protein data on α chains isolated from other kinds of T cells (helper cells) show that they are *N*-glycosylated (Kay, J. & Janeway, C.A. *J. Immun.*, in the press), whereas the sequence reported by Saito *et al.* in *Nature* has no *N*-glycosylation sites. Moreover, Tonegawa reported in Aspen that three 'α' clones isolated from independent cytotoxic lines all contained the same *V* and *J* segments.

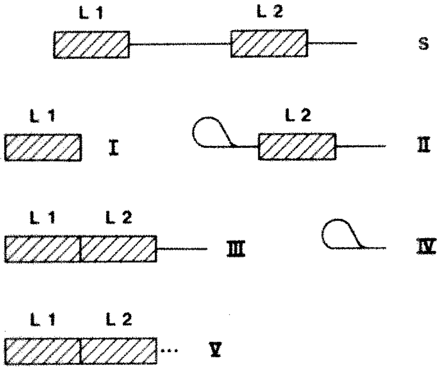
Leroy Hood (Caltech) argued in Aspen that such invariance was inconsistent with a role in antigen recognition, although others have pointed out that there is a precedent in the λ light-chain genes of mouse immunoglobulin, which have only two variable-region segments. Moreover, variation in the exact site of the *V–J* join in the cDNA of the three T-cell lines analysed by Tonegawa does in fact generate some diversity that could, as he pointed out, have a significant effect on antigen binding, or on binding of the MHC molecules that form a necessary part of the antigenic stimulus of T cells. And as Tonegawa emphasized, the genomic DNA corresponding to the clone is rearranged and expressed exclusively in T cells and has clear homology to immunoglobulin, both in sequence and in organization, and thus fulfills all the important criteria for a T-cell antigen-receptor gene.

Thus at the time of the Aspen meeting it was unclear how far the discrepancies between the protein and the DNA data on the α chain should be attributed to differences between man and mouse, or cytotoxic and helper cells; and how seriously the small size of the *V*-segment repertoire should be taken.

More definitive evidence is now becoming available and will this be the topic of a later article in *News and Views*.

Erratum

Excisions of introns in lariat form



In the article 'Excision of introns in lariat form' by Charles Weissman (*Nature* **311**, 103; 1984), an incorrect version of Figure 1 was used. This was a result of a series of errors in the *Nature* office, for which we apologize. The correct figure is shown here on the left. It illustrates the structures of the products (I–V) of cell-free splicing of a substrate (S) RNA composed of two exons (L1 and L2) and two introns. Structure IV is the excised intron in lariat form.

"Nuclear winter" to be taken seriously

IN two recent articles[1,2] John Maddox has criticized our technical analysis of the long-term worldwide consequences of nuclear war[3]. Our findings on what we have called nuclear winter evolved from, and were partly calibrated by, 12 years of related research on martian dust storms, the climatic consequences of volcanic explosions on Earth and the possible collision of an asteroid or cometary nucleus with the Earth at the time of the Cretaceous/Tertiary extinctions.

Given the importance and sensitivity of the subject, we took extraordinary measures to have our calculations reviewed by a large number of experts in atmospheric physics and chemistry, at a meeting specially convened for this purpose in April 1983, and by other means — well before the submission of the paper for publication. Our article refers to some 95 published scientific papers and reports in which further technical details can be found. We have discussed the technical issues with a large number of recognized experts in a variety of fields (which is not to say that all these experts endorse all of our conclusions). Most of the details of our mathematical models are already published, and a detailed 145-page description of our data sources and methodology has been widely distributed. A much more extensive discussion is in preparation.

Some apparently believe that unless nuclear winter is demonstrated beyond a shadow of a doubt, it is dangerous to discuss it in the scientific literature and in public forums. But this is not a subject amenable to experimental verification — at least not more than once. We hold, to the contrary, that open and informed debate on this issue is the only responsible approach, given the gravity of the potential climatic catastrophe we believe we have uncovered.

Whether Maddox has carefully read the work he is criticizing is open to some doubt. He seems to have missed the point that the major cause of nuclear winter is sooty smoke from fires rather than silicate dust raised from the surface. We clearly state that the greatest climatic effect is from smoke generated in the burning of cities. Nevertheless, in his first article and much of his second, Maddox surprisingly holds that the main climatic perturbation we derive is from dust. That this is not merely a careless use of words is made clear by his repeated comparison of our predictions of the effects of the nuclear war with the frosts produced by volcanic eruptions, exemplified by the work of LaMarche and Hirschboeck[4], who find good agreement between the timing of some volcanic eruptions and temperature declines. Our previous work[5,6] shows that major volcanic explosions in the past few centuries may have produced optical depth perturbations of at most a few tenths, and global temperature declines of at most one degree centigrade. These values are less than even the dust in a nuclear war would probably produce, to say nothing of the soot.

Maddox writes "The chief reason for this huge discrepancy between the consequences of a nuclear war and a volcanic eruption stems from the assumptions made about the quantities of dust carried into the stratosphere by the different events." But our calculations unambiguously show that if there were no dust whatever injected into the atmosphere, and no aerosols of any composition injected into the stratosphere, severe climatic perturbations might nevertheless ensue from upper tropospheric soot. By his statements, Maddox also seems to be unaware that climatic effects of volcanic explosions are caused principally by sulphuric acid aerosols, not by silicate dust. Likewise, our results differ from those of the 1975 National Academy of Sciences report, largely because that study did not consider the injection of soot into the atmosphere from massive fires. But it is also true that the 1975 report did not carefully quantify the dust injection.

Maddox evidently believes that we have not justified or even stated the properties of the dust we employed in our calculation. In fact, we used direct measurements of the particle size distribution of dust produced by nuclear explosions, data on the properties of soils and observations of windblown dust. The log-normal/power law distribution function adopted, the complex refractive index of the dust, and other relevant parameters are explicitly stated.

Nuclear explosions are not volcanic explosions, and the differences between the two kinds of events far outweigh what they have in common. The relative importance of smoke in dominating the attenuation of sunlight in the immediate post-nuclear war environment was first noted by Crutzen and Birks[7]. Our calculations show that smoke is much more effective than dust per unit mass of aerosol, both for optical and for climatic perturbations, because of the greater absorptivity and finer particle size of the former.

Maddox criticizes Covey *et al.*[8] for applying their "new model" to nuclear winter before its applicability has been demonstrated in more conventional calculations of the general circulation. The 'new model' is in fact the Community Climate Model of the National Center for Atmospheric Research, which has been in general use for some years. In our *Science* paper[3] we explicitly noted that the great heat capacity of the oceans will have an ameliorating effect on the post-nuclear war temperature perturbations even in continental interiors, and made a rough estimate of the magnitude of this amelioration. As Covey *et al.* make clear, their three-dimensional general circulation model, as well as one, two and three-dimensional models at Lawrence Livermore National Laboratory and at the Computing Center of the USSR Academy of Sciences, are all in good agreement, in hemispheric average, with our published results. Moreover, Covey *et al.* show that the effects could be significantly worse than we had stated, in that "quick freezes" could occur in a matter of days in areas far distant from the combatant nations, as well as showing that calculated perturbations to the global circulation could bring dust and soot rapidly to the tropics and into the Southern Hemisphere, as we had originally proposed.

There are many points about nuclear winter that require further work, both theoretical and experimental. We have never suggested that the last word has been said on this subject[9]. We have, however, run some 50 different cases, to study uncertainties and sensitivities, in many of which, including those we consider most likely, the climatic effects are very severe.

There are contingencies, which we consider unlikely, that could mitigate the severity — for example, if the smoke is everywhere efficiently scavenged from fire plumes, or if there is persistent mesoscale patchiness in the aerosol cover. But there are also circumstances, some of them very likely, in which the effects could be considerably worse. For example, the smoke from fires set by one nuclear explosion over a city can be propelled rapidly by a later explosion to very high altitudes, where it is immune to scavenging mechanisms. By creating channels for bomblight and by drying, a first nuclear explosions over forests can enhance the burning produced by a subsequent nuclear explosion. We have also entirely ignored the effects of tactical nuclear weapons; there are now almost 35,000 of them in the world inventories, many with yields greater than those of the bombs that destroyed Hiroshima and Nagasaki.

The dramatic restructuring of the Earth's atmosphere by injected aerosols moves the lower atmosphere towards isothermality and the upper atmosphere towards a major thermal inversion, as shown in our *Science* paper. In a fully interactive calculation, this restructuring would significantly prolong the duration of the climatic effects following a nuclear war. The snow/albedo and sea ice/thermal inertia (see ref. 10) feedback effects also act to extend the duration of nuclear winter.

As one measure of the importance of the nuclear winter problem, within the past few months major research efforts, costed at many millions of dollars, have been authorized in the government laboratories of both the United States and the Soviet Union, and still larger programmes are under urgent consideration. Spokesmen for the US Department of Defense have recently testified that they take nuclear winter very seriously[11].

In the closing paragraph of our *Science* paper and elsewhere in the text and notes, we summarize our view of the limitations of this research and express the hope that, because of these new dangers of nuclear war, "the scientific issues raised (here) will be vigorously and critically examined". Many members of the scientific community, ourselves included, are now engaged in such an examination.

JOHN MADDOX REPLIES — My objective, in the first brief reference to this work and in the second reference, was to remind readers, either of the original works or of *Nature*, that these calculations are uncertain. Plainly I should have made more of the smoke and less of the dust, but the conclusion remains — that the assumptions on which these calculations are based, and the computational techniques themselves, are respectively (but necessarily) so uncertain and imprecise that it would be folly to regard them as more than suggestive, but interesting and even valuable (as I said) on that account.

Uncertainty about the scale on which nuclear war might be waged is probably unavoidable, and I have no complaint at the scenario used; it serves the purpose. The uncertainty about the quantities of smoke generated, the height to which smoke would be carried, the local meteorological effects with which its generation would be attended and the rate at which particles would aggregate and be washed out cannot be processes that could affect the quantity of smoke available for redistribution over the surface of the Earth by one or more orders of magnitude.

Even the climatic modelling is susceptible to sources of error not yet taken account of. The essence of the nuclear winter is a global temperature inversion: how stable is this against lateral variations? The point has not to my knowledge been tested. And there has been no investigation of the likelihood that such an inversion would be formed, by the diffusion of carbon particles over the surface of the Earth, without provoking the vertical movements in the atmosphere whose effect might well be to inhibit the temperature inversion altogether. I acknowledge, of course, that this is a difficult and, for the time being, an intractable problem; the authors have followed other modellers in solving the easy problems first. On such a matter, certain to stir the public imagination, it seems to me improper that the results of calculations should be published even in sober language without a warning to all potential readers of the pitfalls there must be. This is doubly unfortunate when, as on this occasion, a purportedly scientific publication is so fully amplified by popular articles, first in *Parade*, most recently in *Scientific American*.

I do not believe that the authors are politically motivated, except in the most general sense that they believe they may help to save the world. But I think it disingenuous of them to overlook the ways in which their conclusions may be used by politicians in other causes, often of a political character. ☐

Amino acid transport systems

SIR — We are concerned about the problem of making simple and unambiguous reference to well-characterized amino acid transport systems, and we indicate here how we aim to minimize unnecessary further complexities in our use of abbreviations for such systems.

Where a new transport system appears to be simply a variant of a known system, we plan to recognize this close relation with a terminology such as A1, A2, ..., reserving previously unused Roman letters only for more distinctly different systems. In this way we hope to avoid exaggerating complexity. We hope also to avoid evoking any single amino acid where it may be misleading because the system later turns out not to be approximately specific for that amino acid.

For systems for basic amino acids in general, where the mediator appears to accept these amino acids only in a cationic form, we plan to use the symbol y^+, the positive charge indicating the apparent selectivity for the cationic form. (This symbol omits an initial letter L earlier included in Ly^+ (ref. 1), whereby a single amino acid was too strongly evoked.) Conversely, for systems for dicarboxylic amino acids where these appear to be accepted only in their anionic form, we plan to use the symbol x^-. The plus and minus signs do not merely emphasize the requirement that the amino acid substrates have a positively or a negatively charged side chain; they also allow for the possibility that systems will later be found that specifically recognize and require the uncharged side chain group -COOH or $-NH_2$. We plan then to add a single subscript letter such as A, G, or C (for example, x_A) where it seems desirable to indicate that one of these anionic systems is rather specific for aspartate or glutamate, or includes cystine among its substrates. An important Na^+-independent system for anionic amino acids, x^-_C, does indeed include cystine and glutamate among its substrates. When a transport system x^- and y^+ is Na^+-dependent, we propose to indicate it by making x and y capital letters, X^- and Y^+. Specification as to the cell type or organelle under consideration will generally be needed when referring to a particular system, especially for a system apparently peculiar to one or a few tissues.

The terminology x, y may be seen as part of a scheme x, y, z, in which z stands for 'zwitterionic'. This leaves the as yet unassigned letter z for one or all systems for zwitterionic amino acids. The letter N is preempted for another meaning[2].

We do not necessarily mean to complicate matters by these ideas, by changing nonconforming abbreviations which may be regarded as already well established, even the capital L in the classical system[3], although a lower case l (as in l3, l4, ...) will seem appropriate for new similar Na^+-independent systems. We think it is important that a transport system should be characterized in detail before a code is designated for it. The various designations need even then to be regarded as provisional, as the homogeneity of a given component of transport is itself a provisional conclusion, and two components may turn out to be less similar than was at first supposed.

We invite colleagues who come to participate in identifying such transport systems to join us in a general effort for reasonable simplicity.

Where is the revolution?

Electronic publishing will bring a new vitality to science. Michael Buckingham evaluates the promise and the problems.

WHEN Gutenberg invented moveable type, there was no doubt about how the new technology would be applied. Electronic publishing is in no such happy situation. The technology exists and certain benefits have long been clear, not least scientifically. But where, the scientist may reasonably ask, is the revolution in communication which will change his working life?

Electronic information systems such as *Chemical Abstracts, Index Medicus* and *Excerpta Medica* have been with us for some years, and are recognized to offer a better service than their printed equivalents. Hitherto, these services have entailed asking library staffs to conduct a search, but increasingly desk-top computers and word processors are being used to gain entry to them, while managers of the database systems are offering means of access which are simpler and cheaper than before. These developments give scientists freedom and flexibility, as well as the obvious physical convenience of being able to search electronically throughout many years' issues rather than physically to manhandle the printed volumes, while the quality of the searches is improved by using combinations of search terms in a way that would be impracticable with printed text. For these secondary services, electronic access continues to gain ground at the expense of the printed version.

. . . even enthusiastic supporters of electronic publication have to admit that presentation suffers in the process.

But what of the primary literature? For several publishers, the first step has been simply to make the full texts of some of their most important primary journals into computer databases. Thus the American Chemical Society last year made a series of its titles available in this way while, in the biomedical field, Elsevier has offered the rapid-publication journal *IRCS Medical Science* as a full-text database updated simultaneously with the appearance of the printed issues. This year, *The Lancet* and the *British Medical Journal* will become available in database form. Books are not being neglected. Saunders and Churchill Livingstone are active in making their medical textbooks available electronically; the Martindale *Extra Pharmacopeia* is now on-line; and Wiley has made its *Medical Research Directory* into an on-line file which reports work in progress in academic, hospital and government institutions.

The benefits for the reader of electronic access can be substantial. Because of postal delays alone, the advantage of speed is considerable — the reader of a British journal in the United States can see articles up to a month ahead of delivery of the printed issues and can also circumvent the delays of circulation lists. Moreover computers can be used to search past issues and deliver the text of articles immediately, without activating the ponderous processes of inter-library loan. The user of a textbook has the benefit of always reading the latest edition. But even enthusiastic supporters of electronic publication have to admit that presentation suffers in the process. Reading articles on a terminal screen is out of the question. Computer printout, even on the best office printers, lacks the clear, compact presentation of good typography, while the loss of illustrations may be unacceptable. Where papers are short, and rapid publication is a prime objective, then the advantages of electronic publication can be decisive. A 3,000 word paper, on the other hand, is all but totally unmanageable on-line, at least with present technology.

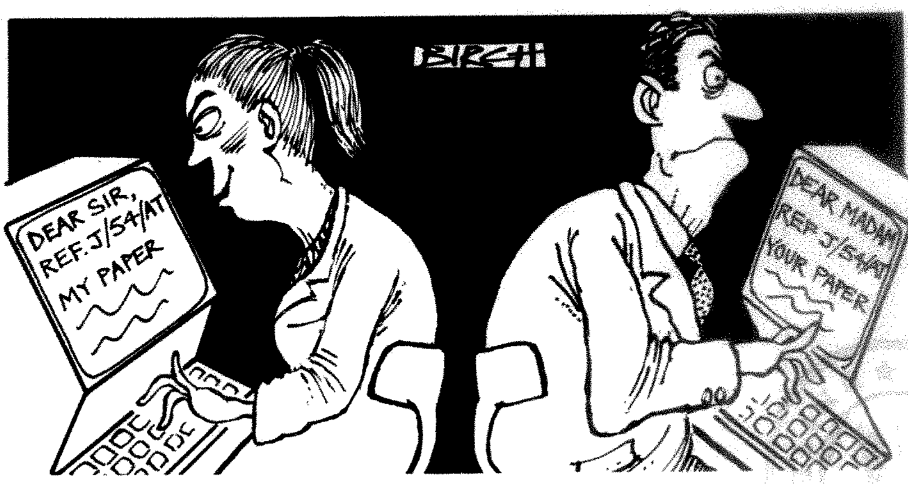
These developments are obvious first steps, but we are still far short of a revolution in scientific communication. Making the text of more journals available electronically is not the answer, nor is the simple speeding up of the information process by making titles, abstracts and bibliographic data accessible through databases. The real task is to develop electronic forms of communication based on a pragmatic understanding of the medium and of the needs of scientists. What can electronic publishing offer that printed journals cannot match? And how can such services better the convenience of dropping into a library at regular intervals to scan favourite titles and look through *Current Contents*?

The early emphasis on converting printed databases to electronic form has tended to overshadow one of the main advantages of computers — the fact that they offer an *interactive* means of communication. Once entered into a system, new information can be collated with existing entries, immediately updating the response to new enquiries. Thus we have an opportunity to introduce a new dynamism into scientific communication, countering the main weakness of the traditional journal.

I have elsewhere said that reading traditional journals is like entering a well kept cemetery; the papers stand in ordered rows, timeless and unchanging. Journals emerged as means of scientific communication when public lecture and debate became impracticable, but much was lost in the process. Scientists continue to talk to each other, of course, at congresses and symposia, but these can be attended only by a small proportion of the workers in any field. And the bibliographic problems associated with recording the proceedings of many meetings mean that much information is effectively lost once the meeting is over.

. . . reading traditional journals is like entering a well-kept cemetery.

The concept of an electronic journal receiving manuscripts by telephone and combining a comment and message service is not, of itself, new. Much of the early work undoubtedly became entrapped in the technology — summed up in the immortal words of John Senders: "I have seen the future and it doesn't work" — but things are changing. In Britain, the BLEND experiment (Birmingham and Loughborough Electronic Network Development), sponsored by the British Library, has provided a successful form of electronic communication for participants, though it has not yet been a vehicle for a great deal of formal original publication. And there are some commercial developments, notably in medicine. In Britain, Elsevier is launching *Clinical Notes On-Line*. This will be an electronic information service, based on submitted and reviewed material, in which



feedback from readers will play a crucial role. In the United States, 3M Inc. is sponsoring the development of a "Bulletin Board" service for the medical profession; the Minnesota Medical Conference Tree has 21 sections ranging from cardiology to general surgery to which physicians can contribute ideas.

These services have emerged to serve particular specialist groups. To meet the needs of the vast range of basic scientific research will be more demanding. In particular, it will be necessary to define the formal status of electronically published work — the role of the peer-review system has to be protected for exactly the same reasons as apply to the printed word. The basis for citation of the work must be equally clear, and some form of archival record must exist. These considerations probably mean that there will still be a need for a printed form of each record, although this need not necessarily be bound and circulated as a conventional journal.

. . . if publishers have to learn new skills, it is reasonable that editors and contributors should do so as well.

Because of the continuing role of printed publications it is entirely possible that electronic debating chambers will grow piecemeal from the electronic publication of existing journals. *IRCS Medical Science* now offers a comment facility, and *The Lancet*, with its strong Letters tradition, is almost an instant electronic forum. But where a journal is not already published electronically, it is arguably easier to start afresh. Whatever the case, contributions will certainly have to be vetted before being made available; editors will still have to edit, and not be seduced by the ease of transmitting the raw material submitted to them; and authors will have to be discouraged from allowing the opportunity to add postscripts to become a substitute for forethought. But if publishers have to adapt and learn new skills, then it is reasonable to ask that editors and contributors should do so as well.

There is a further factor, which being financial may well be decisive. All electronic services charge the reader directly according to the amount of information received. As things are now, a library is a general overhead provided at little direct cost to the individuals using it. Adjusting to a pay-as-you-go system will be traumatic; budgetary responsibility will move away from the librarian to the reader. The true challenge for all concerned, but most of all for the publishers, is to produce services that not only realize the tremendous potential of electronic publication but give immediate value for money. That challenge is a familiar one in selling newspapers but augurs a revolution for scientists and their publishers. ☐

Michael Buckingham is Managing Director of Elsevier-IRCS Ltd, Lancaster, UK.

New journals June 1982 to May 1983

Criteria for journals to be considered for review in this issue were circulated to publishers earlier this year, and were also published in *Nature*. They were that:

(i) the first number appeared, or the journal was re-titled, between June 1982 and May 1983 (although journals not covered in the previous review issues were also considered);*

(ii) the journal appears at least three times a year (two exceptions have been made to this rule);

(iii) the main language used is English;

(iv) where possible four issues should be made available for review, the first, the most recent, plus two others.

Last year's journals review supplement covered publications appearing between June 1981 and May 1982 and the second cut-off date, May 1983, allows for enough issues of a journal to have been published for a reasonable sample to be available for judgement (most are quarterlies). A spread of four different issues is taken as being the usual minimum on which reviewers' comments can be based.

Several journals known to satisfy the above criteria were not submitted for review, or arrived only in August or September, and therefore are not covered in this issue. It proved impossible to find reviewers for other, doubtless worthy journals, while some titles were considered to be of marginal interest to *Nature's* audience.

The brief given to reviewers was to limit themselves to comment on the publications sent to them, and to avoid discussion of general questions of periodical publishing. Opinions expressed in the reviews are based on a sample, and apply to mid-1983 at the latest. As in previous years, the preponderance of journals in the biological sciences reflects the bias of the material submitted for review, and the shortest possible (unconventional) abbreviations of titles have been used in the reviews.

Details of editors and frequency of publication, and the basic annual subscription rates appearing at the top of each review are given in most instances for 1985. These details are not complete in all cases, and readers interested in subscribing to a particular journal should check the rates with the publisher concerned.

Computing communications

W.F. Clocksin

New Generation Computing: An International Journal on Fifth Generation Computers.
Editor-in-chief T. Moto-oka.
Springer-Verlag. 4/yr. DM 250, $96.
Integration: The VLSI Journal. Editor-in-chief L. Spaanenburg.
North-Holland. 4/yr. Dfl. 250.
Technology and Science of Informatics. Editor-in-chief Bertrand Meyer.
North Oxford Academic, 242 Banbury Road, Oxford OX2 7DR, UK. 6/yr. £60, $96.

THE conventional computer designs established by Alan Turing and John von Neumann have begun to encounter numerous difficulties; most particularly, low software productivity and insufficient processing power on non-numerical data have led to the so-called "software crisis". In response, promising new ways of thinking about computation have emerged at the intersection of hardware and software studies. One result has been VLSI (Very Large Scale Integration), a semiconductor technology which makes possible the fabrication of electronic circuits having hundreds of thousands of transistors on an area the size of a fingernail. On the software side, it is becoming increasingly appreciated that the mathematical properties of functional and relational programming languages (such as Prolog) are suitable for specifying logical inferences and computations in an inherently parallel fashion. Such parallelism promises to make effective use of the host of computing elements provided by VLSI technology.

These interconnected technical issues, taken together with planned applications in natural language processing and knowledge engineering, constitute the new generation of computing, and a journal sympathetic to these aims seems sure to be well received. *New Generation Computing* (NGC) shows every sign of fulfilling its potential as the forum for researchers in this area. The need for a new journal is well justified, not the least because of the appalling publication delay in most computer science journals. Credit is due to the Institute for New Generation Computing in Japan for instigating this journal, and for showing from the start a concern for technical and scientific issues.

All of the papers appearing in NGC are in English, but while most of them have thus far originated from Japanese researchers I predict that representation will become more widespread as the field matures. The publisher has done a fine job of packaging and presentation, although in some articles the standard of English (an unfamiliar language to many contributors) leaves much to be desired, requiring considerable imagination on the part of the reader — greater editorial intervention seems to be called for in this regard. Similarly the scientific standard of the papers is somewhat patchy, although this will undoubtedly improve in the future. Each issue of the journal contains about eight papers, many of them short notes of some six pages in length, and there is usually an editorial and a non-technical "leading article" of a more general nature. The journal needs to do some growing up, but my overall impression is that NGC will prove to be indispensable to those who need to be kept informed of developments as the fifth generation approaches.

Integration: The VLSI Journal is a natural partner to NGC. The title *Integration* is an appropriate if unintended *double entendre*, for the coverage of this journal is of interest to the mathematician and computer scientist as well as the electrical engineer. Editorial policy stresses the mutual benefit of communication between these practitioners, and this is a very healthy sentiment which I hope propagates more widely to industry. Certainly, *Integration* will be a valuable addition to the literature serving the computer scientist and engineer.

The papers published in the journal rise to the challenge laid down by the editors and are of high standard. Like NGC, *Integration* has an admirably short publication delay, and also includes a number of departments — letters to the editor, news and a calendar of events, and abstracts of a dozen or so relevant papers published elsewhere. Quality of illustrations is important in reports of VLSI work, and monochrome photographs and half-tones are reproduced to a high standard. As yet, no colour plates are in evidence, however, and no advice on submitting coloured photographs is given, but colour does not seem to be out of the question because both the cover and one advertisement sport the appropriate hues.

Compared with *Integration*, *Technology and Science of Informatics* (TSI) has a wide coverage and is intended to appeal to the more general audience of computer professionals. The journal is a cover-to-cover translation of the French publication, *Technique et Science Informatiques*, and classifies its papers under the three headings "Surveys", "Applications" and "Research". Each paper is introduced by a few paragraphs of commentary by a member of the editorial board. In addition, there are plenty of photographs and line drawings, and there is a relatively large departmental section with correspondence, reviews, bulletins and calendar. The four or five papers appearing in each issue are not dated, giving no obvious clue to publication delay.

It would be natural to find a French emphasis here and, indeed, most of the reviews are of books written in French and the format is identical to that of the parent journal. The publishers have clearly gone to some trouble to translate the papers well, though there is the occasional bloomer; in one article on Unix, for example, the phrase "branching catalogue" should have been rendered "tree-structured directory".

TECHNOLOGY AND SCIENCE OF INFORMATICS

The advantage of TSI is that it offers a direct line to the French computing community, and it will meet the needs of those especially interested in knowing what is happening across the Channel. □

W.F. Clocksin is an Assistant Director of Research at the Computer Laboratory, University of Cambridge.

Standard reading

A.M. Addyman

Computers and Standards.
Editor-in-chief John L. Berg.
North-Holland. 4/yr. Dfl. 262.
Interfaces in Computing.
Editors R.W. Dobinson and P.N. Clout.
Elsevier Sequoia. 4/yr. SwFr. 195, $92.75.

THE advent of *Computers and Standards* (CS) reflects a growing awareness of the need for standards within the computing industry. Unlike most journals in the general area of computing, CS is not limited to one topic such as programming or computer architecture. Rather, it addresses standardization, which affects virtually all aspects of computing. Indeed there is an increasing number of branches of the subject in which the only effective way forward is through the standards process.

Most of the information in CS appears in the form of papers and commentaries; why some contributions are classified as papers and others as commentaries is not clear — to me at least. The quality of the material is, generally, very high, which is only to be expected as many of the authors are well-known and very active in standardization work. Recent issues have contained contributions on the programming language

A choice of new journals from Karger

Acute Care
International Review of Critical Care Medicine
An instructive guidance for all specialists working in intensive care units who require access to the newest developments in emergency care procedures.
Editors: M.H. Weil, North Chicago/Ill.
E.C. Rackow, Chicago/Ill.
1985: Volume 11 with 4 issues
Institutional subscription: SFr. 218.-
Personal subscription: SFr. 109.-

Digestive Surgery
A new reference to basic research as well as advances and technical innovations in a diversity of fields relating to surgery of the alimentary tract.
Editors: E.H. Farthmann, Freiburg i.Br.
L.F. Hollender, Strasbourg
1985: Volume 2 with 4 issues
Institutional subscription: SFr. 246.-
Personal subscription: SFr. 123.-

Experimental and Clinical Immunogenetics
A guide to the explosive growth of research in immunogenetics and its emerging clinical applications.
Editor: K. Bauer, Heidelberg
1985: Volume 2 with 4 issues
Institutional subscription: SFr. 198.-
Personal subscription: SFr. 138.60

Pediatrician
International Journal of Child and Adolescent Health
Problem-orientated topic issues pertinent to practitioners for the maintenance of international expertise on psychological problems and medical disorders with special emphasis on ambulatory pediatrics.
Editor: D.W. Kaplan, Denver/Colo.
1983/85: Volume 12 with 4 issues
Institutional subscription: SFr. 180.-
Personal subscription: SFr. 90.-

Pediatric Neuroscience
Successor to 'Child's Brain'
Experimental and clinical studies featuring new information and observations in pediatric neurosurgery as well as neurology, neuroradiology and neuropathology.
Editors: E.B. Hendrick, Toronto/Ont.
D.H. Reigel, Pittsburgh/Pa.
1985: Volume 12 with 6 issues
Institutional subscription: SFr. 330.-
Personal subscription: SFr. 181.50

Psychopathology
International Journal of Descriptive Psychopathology, Phenomenology and Clinical Diagnostics
Research centered on the concepts, models, and diagnostic categories that guide the practice of psychiatry and help illustrate the dynamics of psychopathologic phenomena.
Editors: P. Berner, Wien, E. Gabriel, Wien
1985: Volume 18 with 6 issues
Institutional subscription: SFr. 254.-
Personal subscription: SFr. 177.80

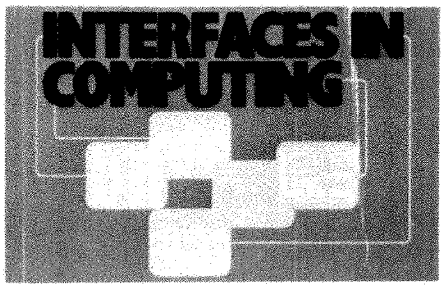
KARGER
S. Karger AG, P.O. Box, CH-4009 Basel, Switzerland

KI 84256

Circle No.10 on Reader Service Card.

COBOL, open systems interconnection (OSI) and database management systems, in addition to a number of articles dealing with the process by which standards are produced and the implications of standards production. As well as the main contributions, each issue of the journal contains details of standards activities and standards publications.



Much of the content of CS will be of particular value to organizations in the computing industry, because the development of standards affects the market for their products. The libraries of educational establishments will find there is less demand for the journal, unless their researchers are active in such fields as programming languages, graphics, databases or computer networks. The key to the success of CS is the fact that the information it contains is generally very difficult to obtain unless one is actively involved with the work. However, the publishers will need to ensure that the delays between the receipt and publication of papers are reduced, because of the perishable nature of much of the information on standards.

Elsevier Sequoia, the publishers of *Interfaces in Computing* (IC), cannot be criticized for tardy publication — the time from receipt of a manuscript to its appearance in print is typically six months. This is essentially a practical journal — like *Software: Practice and Experience*, for example — and it has a fresh, down-to-earth quality. Many of the papers have been written by authors who have created something and are writing from experience; the paper is the result of their work not the reason for it!

Even though there are interfaces in every piece of computer hardware and software, the variety of topics embraced by IC is truly surprising. Subjects covered recently include computer transcription of machine shorthand; device-independent graphics; a pipelined multimicroprocessor system; Cambridge Ring interfaces; CAMAC; and entity relational database systems.

The scope and nature of this journal is such that many computing professionals will find at least one paper of interest in each issue, though the large number of contributions dealing with hardware will probably mean that computer engineers will find more than their software counterparts. Certainly, I will add it to my list of journals to be read. ☐

A.M. Addyman is in the Department of Computer Science at the University of Manchester.

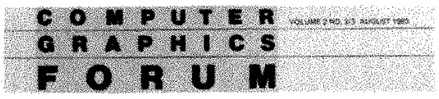
Graphic applications for Europe

Julian Gallop

Computer Graphics Forum.
Editors Günter Enderle and David Duce.
North-Holland. 4/yr. Dfl. 222.

COMPUTER graphics has become accessible to the layman since personal computers with graphics have become more sophisticated and cheaper, and many magazines are available to such readers. The professional user, practitioner or researcher has different requirements, however, and there are far fewer relevant journals available.

Computer Graphics Forum (CGF) is the official publication of the European Association for Computer Graphics (Eurographics) and is now in its third volume. (For an individual, joining Eurographics and thereby obtaining CGF free is cheaper than buying the journal separately.) The text is edited and typeset with computer assistance and the quality of production is good and (after the first volume) uniform.



A typical issue contains refereed technical articles; reports and announcements; and Eurographics association news. The technical articles (generally 5–15 pages in length) cover various applications of computer graphics (for example, in chemistry, molecular biology and population planning) and studies in theory or techniques (for example, contouring, picture processing and geometric modelling). The number of articles varies perhaps too widely between one issue and the next; the average is about four to five an issue. This is a rapidly changing field and CGF aims to publish refereed articles quickly. In general, this is achieved, but there has clearly been some publication delay when colour photographs are reproduced on the same pages as text. Occasionally, colour photographs seem to have been included gratuitously and do not add information, notably the pictures of a VDU screen that is virtually a single colour.

Part of CGF is devoted to reports, announcements and surveys. Important events in Europe, and some outside, are announced and reported, including meetings, workshops and conferences. In this part of the journal a book review section has recently been started.

There are parallels between CGF and *Computer Graphics*, published by the Siggraph Association (Special Interest Group on Computer Graphics). However, while international, the latter has a strong North American emphasis and CGF is providing a focal point for refereed technical articles of European origin. In addition, the Siggraph technical contributions are largely concentrated on its conference proceedings and on the very valuable and thorough annual bibliography on computer graphics.

By contrast with other journals in this area, a strong theme in CGF is the standardization of computer graphics. Progress reports, articles on the interpretation and use of standards, and a survey of implementations of the computer graphics programming Standard have been published. Also, an algorithms section has been announced and if successful will encourage the exchange of software using the Standard. □

Julian Gallop is a Senior Scientific Officer in the Central Computing Division of the Rutherford Appleton Laboratory, Chilton, Oxfordshire.

CAL tech

D.J. Malcolme-Lawes

CAL (Computer Applications in the Laboratory).
Editors Lawrence P. Forsley, David W. Grant, Rudolf E. Kaiser and Anthony J. Rackstraw.
*Alfred Heuthig Verlag, PO Box 102869, D-6900 Heidelberg 1, West Germany.**
6/yr. £30, $50.

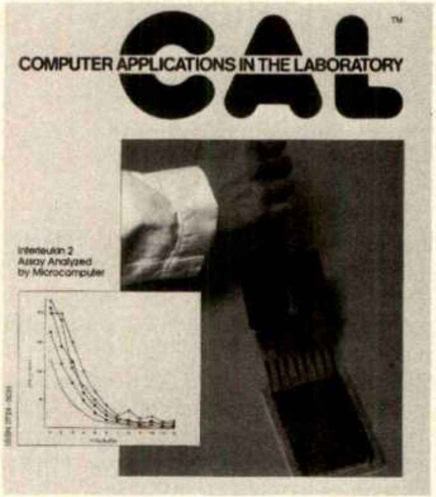
AMIDST the welter of magazines feeding the public appetite for computing at home, we are now seeing the appearance of publications which attempt to provide a forum for the exchange of information on the scientific uses of microcomputers. One such journal, *Laboratory Microcomputer,* was reviewed in *Nature* last year (**305**, 495; 1983). Another is *Computer Applications in the Laboratory,* launched in March 1983, which apparently wishes to be known as CAL.

As an avid reader of popular computer magazines and a user of laboratory microcomputers, I was moderately excited at my first contact with CAL, and felt that here perhaps was a journal designed for people like me. Sadly this excitement has faded as more issues have appeared.

The publication is well turned out and has many of the features of a popular computer magazine: a glossy colour cover, plenty of photographs, large advertisements, and an editorial and a pattern of sections in each issue. Essentially the magazine is divided into four — news, features, series and "scientific originals". The news items are most commonly one-page articles/advertisements reporting a new computer or program or a conference — FORTH advocates and Perkin-Elmer have dominated so far. Features vary from short reviews of books and programs (e.g. BASIC compilers for Applesoft BASIC), to literature searching, to word processing (although both of the word-processing articles have been on the Apple Writer). The series in the first year have included "Personal computers in the laboratory", "Interfacing", "Learning FORTH" and "6502 made easy". In each case division of the text into different issues was unfortunate because the individual episodes so far have occupied only a small amount of space, and in some instances have contained very little worthwhile information.

The criticisms to be levelled at these three sections are that the hard information content is too low and that selection of topics is too restricted (applications other than chromatography and computers other than the Apple would be of interest). Further, the excessive use of half-page cartoons conveys the impression of a vain attempt to hide a lack of editorial material.

The original work (including short communications) reported in the final section comes from a wider range of contributors and is consequently much more varied. Articles have covered applications of several popular microcomputers, and even the DEC Minc mini. Most of them so far have been on software, covering topics such as the resolution of HPLC peaks, measurement of lung function in babies and children, and electrothermal atomic absorption spectroscopic analysis. The last issue available for review (1/84; volume numbers are not used) contained one scientific original (4 pages) and one short communication (3 pages). That is seven pages out of a total of 60. Not all issues are that low on papers, but even so the serious content is disappointingly small.



COMPUTER APPLICATIONS IN THE LABORATORY
CAL
TM
Interleukin 2 Assay Analyzed by Microcomputer

There is indeed a place for a publication such as this, half journal and half magazine. But if CAL is to satisfy its readers, and not just its advertisers, the editors will have to include more meat and less froth. □

Need for greater vision?

P.W. Hawkes

Image and Vision Computing.
General editor Keith Baker.
Butterworth. 4/yr.
£82, $164.

BRANCHES of science are commonly referred to as fields but the application of computing to imaging and vision is more like a wide sea, spreading over robotics, medicine, military reconnaissance, astronomy, microscopy and a host of other subjects. Thus far it is a shallow sea, however, for despite all the theoretical work there are far more people paddling than swimming. Inevitably, progress is being made on related practical problems in different domains of application. It is in the hope of countering the duplication of results in specialist serials, by collecting together papers of potential interest in several disciplines, that *Image and Vision Computing* (IVC) has been launched by Butterworth.

So far, its success is limited. There are indeed practical papers of general interest but there are others that would have been more widely read in a specialist journal. In particular there are numerous theoretical contributions for which natural homes already exist — the *IEEE Transactions on Pattern Analysis and Machine Intelligence, Computer Vision, Graphics and Image Processing* and *Pattern Recognition* spring to mind. Furthermore, there are only five or six articles per issue, so few that workers in this field will have to look at the other, more-specialized publications anyway. So the case for this new interdisciplinary journal is not very strong.

In addition to original articles, each issue includes a list of related publications in other journals; this list is very short (a dozen or so per issue) but includes long abstracts. It is followed by one or two book reviews (the May 1984 issue contains a review of a book published in 1982), a news feature entitled "Insight", a page or two of "Product News" and a calendar of forthcoming meetings. The latter is useful and easy to consult, though it is not obvious what Applications for Management and Productivity will be discussed at CAMP '84 in Berlin!

It seems to me that there is a serious danger that IVC will attract material difficult to place elsewhere. These first issues do contain some extremely interesting articles—but there will have to be far more of them if the journal is to occupy the place to which its editor aspires. □

P.W. Hawkes is Maître de Recherches at the Laboratoire d'Optique Electronique du CNRS, Toulouse.

Drug design centred

J.M. Midgley

Quantitative Structure-Activity Relationships in Pharmacology, Chemistry and Biology.
Editors Joachim K. Seydel and F. Darvas.
Verlag Chemie. 4/yr. DM 280, $168.

THE elaboration of molecules which will selectively control biochemical processes in a predictable manner is one of the ultimate goals of drug research. Drug design has been defined as the application of rational methodologies which result in a new drug (either through total innovation or via the optimization of a lead compound), and in the past two decades there has been a rapid development in techniques for elucidating quantitative structure-activity relationships (QSAR) for many compounds possessing diverse biological activities.

An indication of the activity in this field is the emergence of a specialist journal, *QSAR in Pharmacology, Chemistry and Biology*, which has a distinguished editorial staff drawn largely from academia in Europe and the United States. The purpose of the journal is "to collect contributions on all aspects of the subject embodied in its title", in particular theoretical and methodological aspects and innovative applications of QSAR. Each of the four issues published annually contains about four refereed contributions (averaging five to six pages in length) of original research, and a balance of subject matter within the editorial remit has been achieved so far. The articles are clear and succinct, and their scientific standard is comparable to those of a similar nature appearing in established journals. The papers largely originate from Europe and the United States, and the significant industrial contribution reflects the growing economic (as well as scientific) importance of QSAR.

ACID PRECIPITATION DIGEST

Each monthly issue provides capsule summaries of —

- news items
- books
- technical reports
- periodical reports
- conference proceedings
- peer reviewed literature
- calendar of upcoming conferences and events
- documents

Acid Rain Information Clearinghouse
a project of the
Center for Environmental Information, Inc.
Department N, 33 South Washington Street
Rochester, New York 14608 (716)546-3796

Circle No.34 on Reader Service Card.

Somewhat surprisingly, there is no editorial comment or opportunity for correspondence and the remainder of each issue is taken up with approximately 60 abstracts of publications related to QSAR; these are comprehensive and drawn from diverse sources, but may be too dated to excite the *aficionado*. The whole is produced in a modern two-column format, with clear print and illustrations.

At the price the circulation may be confined to libraries and dedicated investigators in the field. The period from receipt to publication of the articles is variable, often only comparable to that in established international journals, so that research workers may opt to present their more interesting findings to a wider readership rather than preach to the converted. ☐

Picture chemistry!

Peter Kollman

Journal of Molecular Graphics.
Editor A.J. Morffew.
Butterworth. 4/yr. £55, $110.

THE *Journal of Molecular Graphics* (JMG), published in association with the Molecular Graphics Society, was founded to give "computational scientists" a forum to publish their work. The importance of computer graphics in studies of molecular systems, in drug design and in X-ray crystallographic studies of macromolecular structure has begun to be appreciated by many chemists. Indeed I am among the converts to the view that computer graphics is an essential tool for any chemist studying even moderately complex molecules. A corollary to this is that well-written computer software is often crucial in asking the most pertinent questions about a particular molecular system, and in answering them. Thus, there should be mechanisms for publication of software approaches to the solution of chemical problems and for giving due credit to elegant software.

In this context, it should be noted that *Computers and Chemistry* (launched in 1976) and the *Journal of Computational Chemistry* (which first appeared in 1980 and was reviewed in *Nature* **299**, 513; 1982) are journals where descriptions of both computer software and its applications are already welcomed. Of these two, it is significant that the latter has been the more successful because it has attracted a mix of software descriptions and applications of high quality and interest to many scientists.

In its first four issues, JMG has published articles mainly on computer graphics algorithms. Sample applications of the algorithms often occupy a small part at the end of the article and typically the papers do not have a strong scientific punch-line. One cannot blame the authors for saving their scientific message for journals where more chemical scientists will read them, but in my opinion the separation of computer graphics from other areas of computational chemistry is not a good idea. Besides the regular articles, the journal has also included a bibliography of molecular graphics applications, abstracts from the meetings which include computer graphics, and descriptions of new computer products of potential interest to chemists.

One commendable advance made by JMG is to combine colour figures from the individual articles into a central section of colour, thus allowing high-quality colour pictures to be published without charge to the authors. The science itself can often be delivered most effectively with colour figures, yet most journals charge a large amount for publication ($1,000–$2,500 by the *Journal of Medicinal Chemistry, Journal of the American Chemical Society* or *Proceedings of the National Academy of Sciences*) and often also require colour-separated prints (for example the *Journal of Computational Chemistry*).

The appearance of this journal has certainly facilitated the publication of articles dealing with computer graphics, particularly in the approaches requiring examples in colour. Whether it will thrive will depend on many factors, principally whether the field of molecular graphics will emerge as a separate discipline or whether the journal can attract articles which appeal not only to the molecular graphics community but to a broader constituency of chemists. How the focus could be broadened is not clear, but the very title of the journal cannot help but give the impression that papers other than those dealing explicitly with graphics are less likely to be accepted or receive a wide readership. ☐

Peter Kollman is Professor of Pharmaceutical Chemistry in the School of Pharmacy, University of California at San Francisco.

At the interfaces of spectroscopy

K.A. McLauchlan

Computer Enhanced Spectroscopy: An International Journal.
Editor-in-chief H.A. Willis.
Wiley-Heyden. 4/yr. £65, $130.

DATA-handling by computer and computer interfacing to laboratory equipment are very much to the fore in the 1980s, and the basic idea of a new journal to cover such matters is sound. *Computer Enhanced Spectroscopy* (CES) deals with any use of a computer in any branch of spectroscopy. Its contents include data manipulation on- and off-line, library searching, design principles of systems and specific experimental devices; unusually, much software is reported. Authors are invited to publish details which went undescribed in an original scientific paper, a seductive call to double their number of publications.

The problems for the journal, though, are several. Such a range of specialist spectroscopic techniques is involved that the matter dealing with any one topic is dilute. Since in many research fields there exist dedicated journals, it seems unlikely that a seminal paper in, for example, magnetic resonance will make its way to CES. For ideas of inter-disciplinary interest, on the other hand, there exist the well-respected *Reviews of Scientific Instruments* and *Journal of Physics (E)*, which would take most of the material. Many of the practical accounts are device-orientated and concern specific microcomputers and specific types of spectrometer. They are of limited use, for wherever such interfacing is necessary one finds that because of technical advances many problems must be solved afresh. Similarly, software is usually most efficiently written for the precise microcomputer and application in mind, and often not in a high-level language. Some of the basic data manipulation points made in the four issues of Vol. 1 are very straightforward.

The journal is well and attractively produced with excellent reproductions of a wide range of devices, flow diagrams and software. However the first volume does appear to have been short of material, which has perhaps led to the publication of some rather trivial articles. Because of this uncertain start, and the reservations expressed above, I cannot believe that it will become widely read. □

K.A. McLauchlan is a Lecturer in the Physical Chemistry Laboratory, University of Oxford.

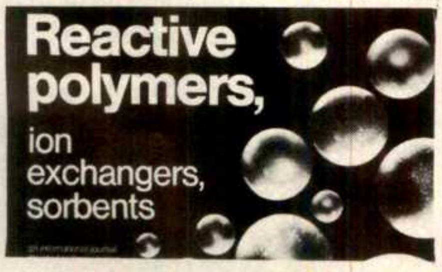
Polymer exchange

Philip Hodge

Reactive Polymers, Ion Exchangers, Sorbents.
Editor-in-chief F.G. Helfferich.
Elsevier Scientific. 8/yr. Dfl. 412, $160.

FOR MOST of its history, polymer science has been mainly concerned with polymerization processes, the physical properties of polymers, and their applications in material science. There are many journals that cater for these areas. In contrast relatively little work has been carried out on synthetic reactive polymers. This is surprising, bearing in mind that nature makes extensive use of polymers in various recognition processes and to catalyse and control reactions between low molecular weight species.

In recent years interest in reactive polymers has increased considerably and *Reactive Polymers, Ion Exchangers, Sorbents* seeks to provide a forum for this underdeveloped area of macromolecular science. The journal is well produced and contains original papers, short communications, reviews, book reviews, letters to the editor and a news page. For the first year it appeared quarterly but eight issues will appear in 1984, surely a sign of good health.



The standard of papers is excellent and there are contributions from many internationally known authors of good reputation. Thus far a rather high proportion of the papers has dealt with ion exchange resins, metal extraction using various sorbents and closely related topics. This bias probably reflects the fact that ion exchange resins are one of the few types of reactive polymers which have been studied for many years and have industrial applications. There are, however, many other areas of interest — polymer-supported catalysts, chemical modifications of synthetic and natural polymers, and biomedical and pharmaceutical applications, for example — and it is to be hoped that the number of papers dealing with these areas will increase to give the journal a better balance.

It is still hard to say how well this journal will fare in the long term. It serves a growing area of polymer science and if it can attract sufficient papers and publish them more frequently, whilst maintaining its present quality, it could do well. □

Philip Hodge is a Reader in Organic Chemistry at the University of Lancaster.

Separate ways

Alwyn McKay

Solvent Extraction and Ion Exchange.
Editors E. Philip Horwitz and James D. Navratil.
Dekker. 6/yr. $150 (US), $166.50 (elsewhere).

THE launching of *Solvent Extraction and Ion Exchange* (SEIE) may well be considered overdue, in view of the enormous expansion in this area since 1945. The journal is a companion to *Separation Science and Technology*, and its appearance follows a questionnaire addressed to specialists in the two related fields.

The first volume of four numbers, published during 1983, contains important material. There are 32 papers, five "notes" (not obviously distinguishable from papers), two valuable review articles and two letters; a bibliography and other items are included in each issue. Volume 2 (1984) will be larger, with eight issues, and it is expected that the journal will be expanded yet further. Certainly, there is plenty of scope for this.

There is, however, a long way to go before the editors' hope of the journal becoming the principal vehicle for papers on solvent extraction and ion exchange can be realized. At present SEIE carries only a small proportion of the total of papers on the subject being published, as the number of entries in the bibliography demonstrates. Moreover the selection is unbalanced in various ways. Academic chemical topics predominate, with emphasis on matters of nuclear interest, and there is little on equipment or industrial processes. On the other hand, the ratio of four solvent extraction papers to one ion exchange paper seems a fair one.

The journal is reproduced directly from the authors' typescripts and diagrams, but despite this it is not particularly cheap. The quality of presentation varies from very good to just adequate; in the worst cases one wishes that the method of printing did not preclude sub-editing to get rid of misprints, poor English and other blemishes. On the positive side, photographic reproduction should speed up publication, and most papers do appear reasonably promptly. The bibliography, however, being based on *Chemical Abstracts* rather than current journal contents lists, is unfortunately somewhat out-of-date.

My verdict is that SEIE indeed fills a gap. But there is some sacrifice of quality to economy and speed of production, and the editors would do well to keep an eye on their standards. □

Alwyn McKay was formerly a Group Leader in the Chemical Technology Division of the Atomic Energy Research Establishment, Harwell, Oxfordshire.

The carbohydrate competition

Neil Baggett

Journal of Carbohydrate Chemistry.
Editor Donald E. Kiely.
Dekker. 4/yr.
$110 (US), $121 (elsewhere).

THE aim of the *Journal of Carbohydrate Chemistry* (JCC), which in part replaces the *Journal of Carbohydrates, Nucleosides, Nucleotides*, is to provide an international forum for aspects of carbohydrate chemistry, excluding polysaccharide studies. This area of chemistry is already served by *Carbohydrate Research*, so that JCC does not fill a vacant niche but competes with the established journal. It is therefore appropriate to compare the two.

The new journal includes original research papers and communications, with some reviews of "timely topics in carbohydrate chemistry". *Carbohydrate Research* does not contain reviews but does cover studies on polysaccharides. Both journals publish articles in English (mainly), but also in French and German. The new journal comprises four issues per year (six were originally promised), so it is much smaller but also much cheaper than its competitor; the two are roughly comparable in terms of price per page. Perhaps the most noticeable difference between the journals is that JCC is reproduced direct from the authors' typescripts, which means that very rapid publication can be achieved but also, on occasions, that minor but necessary editing is not done. Together with the non-uniformity of type, this gives the journal a rather unfinished look, and the principal attraction of JCC for potential authors must be the speed of publication.

The claim to be an international journal is justified. There are representatives from 13 countries on the editorial board and the papers published to date originate from a wide geographical range. There is, however, a bias towards the United States, with almost half of the editorial board and one-third of papers coming from that country.

So far the standard of papers and reviews in the new journal is generally good, perhaps because roughly half of them have been contributed by members of the editorial board. The viability of JCC will depend on whether papers of a similar quality are forthcoming in the future from a broader range of authors, especially if the American Chemical Society continues to expand its range of publications into the area of carbohydrate chemistry. Whilst there are advantages for authors in having two journals to choose between, librarians are not in such a happy position — the standard of the papers in both JCC and *Carbohydrate Research* means that neither can be just ignored. □

Neil Baggett is a Lecturer in the Department of Chemistry, University of Birmingham, UK.

Nucleic acid news

Janet L. Rideout

Nucleosides & Nucleotides.
Executive editor John A. Secrist III.
Dekker. 5/yr. $149.50 (US),
$163.25 (elsewhere).

Nucleosides and Nucleotides (NN) is unashamedly a speciality journal, but one which covers an especially vigorous area of science. Its aim is to concentrate upon the chemistry and biology of nucleosides, nucleotides and closely related compounds, with the chemistry of new entities being emphasized.

Obviously, for this, as for most new journals, success in the long run will depend upon the submission of material from authors who generally send their papers to more established publications. Judging by the eminence of some of the contributors to the first two volumes, NN has made an auspicious beginning. And although the journal is reproduced from camera-ready copy, the standard of production is very high — reviews, original articles and notes are clearly presented, with chemical structures, tables and so on embedded as appropriate in the text.

Submissions are refereed, and must contain experimental details (a refreshing feature to be recommended to the editors of other journals devoted to the rapid publication of scientific research). Authors of review articles are encouraged to include critical comments, and thus far reviewers are responding and are doing more than simply providing compilations of the literature pertaining to a given subject. Lately, abstracts of recent articles and bibliographical data on selected subjects have been added to the journal's contents.

Nucleosides & Nucleotides

Anyone working in this field, or wishing to enter it, will need to refer to NN for information on developments in the chemistry and biology of nucleic acids, for indications of new directions the field is taking, as well as for the comprehensive reviews which appear from time to time. The subscription price is not unreasonable, and altogether the journal seems set for a healthy future. □

Janet L. Rideout is a Group Leader in the Organic Chemistry Department at Burroughs Wellcome, Research Triangle Park, North Carolina.

With the grain

Donald D. Kasarda

Journal of Cereal Science.
Editor T. Galliard.
Academic. 4/yr. £43, $98.

BECAUSE of the enormous importance of cereal grains as food, animal feeds and raw materials, almost every cereal-producing country in the world — from Australia to the USSR — has in recent years made huge investments in cereals research. Such expansion has created a need for extra journals as outlets for the resulting publications. The new *Journal of Cereal Science* (JCS) covers much the same areas as the already well-established journal *Cereal Chemistry*, including research papers (and an occasional review) on topics such as component characterization, nutritional quality, food science and technology, and genetics as they relate to the functional or nutritional quality of cereal grains (unlike *Cereal Chemistry*, however, JCS does not accept papers on legume "grains").

I have the impression that, in addition to a need for more journal space, the impetus for the formation of JCS stemmed partly from dissatisfaction by some scientists (particularly in Britain and France) with what they considered unfortunate reviewing practices by *Cereal Chemistry* that delayed publication of papers. They were also unhappy with the page charges levied by that journal. Since then, it should be said, *Cereal Chemistry* has dealt with many of its problems although the page charges remain.

My examination of five of the six issues out at the time of writing tells me that JCS is doing well; many papers are of a high standard, the quality of editing and of production are good, publication occurs a not-unreasonable six to ten months after receipt of a manuscript, and there are no page charges.

A few papers seem rather pedestrian, however, and such contributions may discourage authors from choosing this journal to publish their better work. On the other hand, authors must contend with the tendency of editors of the better general-science journals to recommend that papers dealing with cereal grains, even reasonably good ones, should be published in speciality journals. Such attitudes, however unfortunate, benefit *Cereal Chemistry* and now, I suspect, JCS as well.

I believe this new journal is here to stay. Not only that, the commitment to improved quality evident in occasional editorials by the editor T. Galliard, and one of his colleagues, J. D. Schofield, should lead to expansion. □

Donald D. Kasarda is Research Leader of the Food Proteins Research Unit, Western Regional Research Center, ARS, US Department of Agriculture, Albany, California.

Agricultural produce

Leonard Broadbent

Crop Protection: An International Journal of Pest, Disease and Weed Control.
Editor G.E. Russell.
Butterworth. 4/yr. £68, $136.
Crop Research.
Editors C.A. Wood, Pauline B. Topham, Jane Bryan-Jones and P.J. Dudney.
Scottish Academic Press.
2/yr. £13.50, $30.
Biological Agriculture & Horticulture An International Journal.
Editor R.D. Hodges.
A B Academic Publishers, PO Box 97, Berkhamsted, Herts HP4 2PX, UK.
4/yr. £19, $33 (personal); £55, $89.50 (institutional).

HORTICULTURE and, in historical terms, its offshoot agriculture, are multi-disciplinary technologies developed during the past 12,000 years. Much more recent is the science-based but energy-intensive production of plants and animals, to which are devoted so many journals. The three well-produced publications reviewed here add to this literature but do not fill gaps in it.

Crop Protection (CP), published since 1982, is attracting good papers from all over the world. An analysis of the four numbers available for review gives 15 papers from Britain, 12 from the United States and 20 from ten other countries, covering every aspect of protection science and practice, including biological, chemical and agronomic control, plant breeding, engineering and economics. It has six well-known and expert editors, and a distinguished advisory board of 15 members drawn from almost as many countries — presumably as bait, as possibly was the initial subscription of £45, which in two years has risen to £68. For this one gets about 48 scientific papers or reviews per volume, averaging ten pages in length, that is, a cost of about £0.14 per page of scientific paper (not counting book reviews). This is expensive: an old-established journal publishes similar papers, with more words per page, profitably at £0.07 per page.

Crop Research (CR) is not new but continues *Horticultural Research*, and remains a journal for the publication of research by the Scottish Crop Research Institute. About half of the papers originate there, and a few are from countries other than Britain. As one would expect from an institute with a good reputation, most of the papers are of high standard, but an editorial board of 17 and five associate editors seems over-weight for an average of ten papers per year; indeed, it has always been difficult to justify the existence of this publication when there are several long-established journals covering the same areas. The advantage of CR is of quick publication, some papers taking only 6-8 weeks from receipt, although the average is nearer 28 weeks (about the same as for CP and for other refereed journals). The cost per page of scientific paper is £0.12 (1984 subscription rate) which again is expensive.

There are many who believe that "biological" or eco-agriculture is distinct from (and better than) "conventional" farming because of its holistic approach. The new journal *Biological Agriculture & Horticulture* (BAH) was started in 1982 by the then seven-year-old International Institute of Biological Husbandry, with the aim of publishing scientifically sound research and reviews "to raise the credibility of the biological system". That this is necessary may reflect sadly upon the blinkered outlook of so many "academic" scientists; on the other hand, applied biologists in agricultural research have long realized the necessity for an ecological approach, and have been publishing sound epidemiological research results for decades.

Eco-agriculture has not, in general, had a good press, because of the tendency of some of its supporters to peddle prejudice as solid scientific fact. The editors of BAH will have to take care that their journal does not follow the precedent, for 58% of the scientific content of the first five numbers consists of reviews and surveys. These, and the 14 papers reporting scientific results, come from ten countries, so the journal justifies its claim to be international. The cost of Vol.2 (1984) is not cheap at £0.16 per small page (if the size remains the same). Four editors are again "advised" by a prestigious board of 23 members, drawn from seven countries. Being a journal of a society it contains conference reports and news, as well as book reviews and notices.

BIOLOGICAL
AGRICULTURE &
HORTICULTURE

There is no doubt that food and fibre production will remain man's greatest challenge for many generations. So there should be ample opportunity for BAH to improve its standing amongst agronomists and scientists in the future. ☐

Leonard Broadbent is Emeritus Professor of Biology and Horticulture in the University of Bath.

Relative value

Julian Davies

Trends in Biotechnology.
Editor John Hodgson.
Elsevier (Cambridge, UK). 12/yr. £28, $49, Dfl. 130 (personal); $165, Dfl.430 (institutional).
Bio/Technology: The International Monthly for Industrial Biology.
Editor Douglas K. McCormick.
Nature Publishing. 12/yr. $78, £70.

FOLLOWING the spate of four-page rumour sheets which accompanied the biotechnology industry in its headlong rush to establish a foothold in the world of commerce, publishers have decided to signal the consolidation of the industry by providing more substantial reading matter for the biotechnologist. In the spring of 1983 Macmillan launched *Bio/Technology* (BT) and Elsevier presented *Trends in Biotechnology* (TBT), both of them intended to create and to meet the need for reliable, intellectual presentations of modern biotechnology. A stablemate of *Nature*, BT will obviously benefit from the association, while TBT is fashioned along the same lines as the excellent *Trends in Biochemistry* (TIBS), a monthly collection of reviews that has a good following in academic circles. The nickname TIBS is well known and a similar mnemonic for TBT would have been a definite advantage. What can we call it? TIBOTS? TOBS? TIBITS?

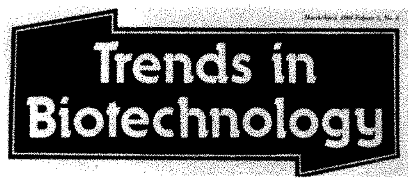
BIO/TECHNOLOGY
THE INTERNATIONAL MONTHLY FOR INDUSTRIAL BIOLOGY

These newcomers to the biotechnology arena offer higher credibility and scientific acceptability than the other publications presently available in this field (with the exception of *Biofutur*; BT is actually more of an English cousin of this French biotechnology journal than a relative of *Nature*). But their serious approach apart, the two journals are quite different in format, presentation and goals.

TBT concentrates on up-to-date reviews of various aspects and developments in biotechnology and does not concern itself with commercial issues. It is essentially academic and pedagogical in character. By contrast, BT provides much information and comment on issues to do with the regulation, investment, business and international aspects of biotechnology and the products so eagerly anticipated. No other publication provides quite the same scope, though there is some overlap with *Nature* in the presentations of the health of the biotechnology industry. BT also includes a rather perfunctory and generally useless summary of new patents which seems to do nothing more than fill space; other patent review journals such as *Derwent Biotechnology Abstracts* and *Telegen Reporter* do the same thing much better.

Both BT and TBT carry substantial advertising. BT has more glossy advertisements than most journals whereas TBT tends to be more conservative. One infuriating aspect of BT is that the longer and better review articles are often interrupted by as many as six pages of advertising, and in some issues the pages of advertising outnumber the pages of text. However, it is comforting to know that the two journals are well-supported in this way.

Both BT and TBT try to address immediate and future problems of biotechnology in the form of reviews. In recent issues, TBT has carried perceptive articles on delivery systems for drugs and enzyme engineering while BT has presented surveys of novel bioreactor systems and the factors involved in the design of pilot plants. Both have good book reviews and are developing interesting "Letters to the Editor" sections. BT includes two or three original scientific research articles in each issue. The articles are related to recombinant DNA applications and are usually of good quality — more or less equivalent to the type of paper published in *Nature*. In fact they probably could be published in *Nature*, were it not for the fact that this would remove one of the justifications for the existence of BT!



One cannot finish discussion of BT without mention of Bernard Dixon, who is clearly one of the more potent commentators on the science/business scene. His articles are sometimes pungent, usually provocative and always worth reading. Perhaps it is in this respect that BT has the edge over TBT — it invites controversy. Yet the question whether the more academic approach of TBT will win and maintain the necessary readership seems to have been answered already; published six times a year until now, it will go monthly in 1985.

The bottom line comes with the question, are these two journals needed? Indispensability is always hard to justify but BT and TBT have quite obviously created a market for themselves. They are clear advances on the rumour sheets and are likely to be the best media for presentations of the science of biotechnology and its academic and commercial implications. The fact that both of them have distinguished editorial boards to oversee their content and shape their future should guarantee their continued quality in a field of publication where quality is rare. ☐

Julian Davies is President and Research Director of Biogen SA, Geneva.

Journal prices

Details of editors and frequency of publication, and the annual subscription rates appearing at the top of each review are given in most instances for 1985. These details are not complete in all cases, and readers interested in subscribing to a particular journal should check the rates with the publisher concerned.

Common ground for new biologists

Bernard G. Forget

Molecular Biology & Medicine.
Editors E.S. Lennox and S. Brenner.
Academic. 6/yr.

TO QUOTE its editors, *Molecular Biology & Medicine* (MBM)

> takes as its main task the provision of a meeting ground between the basic scientist and the clinician, and to build up connections between molecular biology and clinical medicine.

The focus is therefore on normal and abnormal human biology and related research topics in the disciplines of molecular genetics, cell biology, immunology and biochemistry.

In the first five issues, the subjects that have been particularly emphasized include immunology-related research, ranging from studies of monoclonal antibodies (of human as well as murine origin) to analyses of immunoglobulin and histocompatibility genes; molecular genetics of haemoglobinopathies (thalassaemia and sickle cell anaemia); structural analysis of human viruses; and applications of restriction fragment length polymorphisms (RFLPs) to the study of human genetic disorders. The subject matter of MBM is therefore very broadly based and should be of interest to investigators in a large number of different fields. The article thus far published have originated from leading research laboratories, and although the specific reports have not generally dealt with findings worthy of comment in (say) *Nature's* News and Views section, they nevertheless constitute observations of genuine significance.

In addition to research papers (both long and short), the journal also publishes concise reviews of topical subjects — DNA-based prenatal diagnosis of haemoglobin disorders, chromosome translocations associated with leukaemia, X chromosome inactivation, the relationship of growth factors to cancer, and the association between polymorphisms in the major histocompatibility complex and different disease states, are among the topics covered in the early issues. Meeting reports and book reviews are planned but none have yet appeared.

The editorial in the first issue stressed the importance of rapid publication in the fast-moving fields covered by MBM. However this is an aim that does not appear to have been met. A bimonthly publication schedule was planned, but the most recent issue of the journal, dated December 1983, became available only in August 1984 and contained papers received up to 12 March 1984; the cover date therefore does not accurately reflect the actual publication date.

This journal has a very worthwhile purpose in trying to establish a forum where the basic scientist and the clinician can find common cause; the scope and quality of the papers in the first issues give promise that this goal will be achieved. Overall, MBM will be a very useful addition to the libraries of individuals interested in keeping up to date on advances in the elucidation of the pathogenesis of human diseases as studied by the research technologies of the new biology. ☐

Bernard G. Forget is Professor of Medicine and Human Genetics at Yale University School of Medicine.

Records of cancer control

Tony Davies

Cancer Investigation.
Editor-in-chief Yashar Hirshaut.
Dekker. 6/yr. $95 (US), $111.50 (elsewhere).
Journal of Biological Response Modifiers.
Editor-in-chief Robert K. Oldham.
Raven. 6/yr. $80 (personal); $105 (institutional).
Clinical & Experimental Metastasis.
Editors K. Hellman, G. Nicolson, L. Milas and S.A. Eccles.
Taylor & Francis. 4/yr. £49, $98.

THESE three journals have in common an emphasis on cancer research, two of them obviously so from their titles and the third, covering biological response modifiers, because of its strong affiliation to a programme of the same name which is part of the (American) National Cancer Institute research scheme.

Cancer Investigation (CI) is an all-American effort in that all of its editorial and advisory staff work in institutes in the United States, about 30% of them in the Memorial Sloan-Kettering Cancer Center. The papers reflect this bias fairly accurately. The format is glossy, the illustrations of high quality. There is a deliberate attempt by the editors to include a proportion of review articles both on basic and clinical science, while controversies to do with clinical management are given an airing. For example there is a well-argued account of the virtues or lack thereof of staging laparotomy in Hodgkin's disease, and an article strongly critical of the current practice in the United States of performing mastectomy on the majority of breast cancer patients. Also evident are some pointers to technological advances.

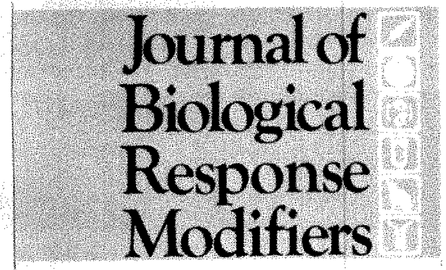
The journal is intended, it seems, to provide a lively account of cancer research for a predominantly clinical readership. The miniseries (*sic*) on oncogenes and cancer led me to believe that here was a splendid archaism, but on reflection I realized that there had been a further enrichment of the English language because of the elision of a hyphen. The editorials are rather pompous and turgid, and censorious of a government which dares to restrict the amount of money put into cancer research. It is not possible to determine how publication time relates to receipt of papers nor is it clear whether or not there is a refereeing system.

The cover of CI displays "Cancer" in big white letters, like its much older antecedent of that name. "Investigation" is added in much smaller black type. As few such journals are likely to attract the casual buyer, such a ploy could hardly be thought deceitful but to a disinterested outsider it seems misleading.

It has always been difficult to define "biological reagents", and the concept of a biological response modifier, apparently coined by Dr Vincent T. DeVita Jr, Director of the National Cancer Institute, is even more complicated. As stated in the *Journal of Biological Response Modifiers* (JBRM), it includes consideration of

> a large number of agents: immunoaugmenting, immunomodulating, and immunorestorative agents; interferon and interferon inducers; lymphokines; cytokines; thymic factors; antitumor and antilymphoid cell antibodies; tumor antigens and modifiers of tumor antigens on cell membranes; antigrowth factors; and maturation and differentiation factors.

Essentially, it means what the Biological Response Modifiers Programme Coordinators want it to mean and anything else for which there is almost a splendid, albeit fictional, precedent. The large editorial board has one or two lonely foreigners known to be sympathetic to the Programme, but the JBRM is so far also predominantly an American effort in content. The argument is advanced, quite fairly, that pressure on other journals makes the new journal inevitable in the welter of "biologicals" emerging from the monoclonal and genetic engineering technological revolutions. Again, no indication is given of publication times.



Journal of
Biological
Response
Modifiers

There are published here opinions on contentious issues in science. For example, Harold Hewitt is given the opportunity to air his well-known opposition to the tumour immunology package and in a subsequent issue Ronald B. Herberman fires back a broadside against such temerity. The papers make lively reading if one can swallow an initial anxiety at the rag-bag of topics. If the contributions to JBRM are well refereed the journal could prove to be a useful addition to the literature, and might even act as a quality control device on the burgeoning "biologicals" industry. But it is, I fear, a crusading effort with little chance that impartiality and objectivity will count for much.

K. Hellman and G. Nicolson are prominent members of that part of the scientific community which gives special consideration to the metastasis of cancer cells. Now they have started their own journal, *Clinical & Experimental Metastasis* (CEM). There are others on the same topic but this has not proved a deterrent. A deliberate effort has been taken to make the journal fully international, in that there are representatives on the editorial board from each of a number of countries in which cancer research is funded. The papers published reflect this international flavour. As yet, CEM contains no frills in terms of the airing of controversies, letters to the editor and the like. The illustrations are good, the papers readable and informative. The publication time is difficult to determine on the first few issues but it seems to be coming down from a year or so to about four to six months. It is implied that there is a refereeing system, the submission times being given separately from a time of acceptance. I find it difficult to understand why journals do not state explicitly what their policy is on this important matter. Much of the work of scientists is judged by their output of papers, which in the good old days could reasonably be assumed to be subject to the regulatory influence of studious and independent refereeing. With such a plethora of new journals it is not easy to know if standards are being upheld.

CLINICAL &
EXPERIMENTAL
METASTASIS

There is little doubt that the technological advances of the past few years will, in time, enable us to control malignant cells in the human body (though the difficulties involved should not be underestimated). All three of the journals will contain a part of the record of progress and they are welcome on this score. But to my mind, well before the story is anywhere near complete, the profligate use of trees to act as the vehicle for scientific pronouncements will have ceased and new information will be surveyed on a television screen. It would have been good to have seen at least a hint that these new journals were preparing for the likely change in medium. □

Tony Davies is Chairman of the Section of Biology at the Institute of Cancer Research, London.

Short of practice in immunology

Gordon Reeves

Diagnostic Immunology.
Editor Mariano F. La Via.
Alan R. Liss. 4/yr. $45 (personal); $90 (institutional).

THE immunological literature is both extensive and fabulous. The clinical immunologist has the dual task of keeping abreast of advances in immunobiology, immunochemistry, immunogenetics and immunopathology, and of assessing their relevance to the study of human disease. The first requirement is well served by the excellent *Annual Review of Immunology* and *Immunology Today*. But what of the practice of clinical immunology? Of the various journals which purport to cover this end of the spectrum, only *Clinical and Experimental Immunology*, in my view, maintains a consistently high standard. Nevertheless, the need for a journal which seeks to improve the quality and organization of current practice, as identified in the editorial for the first issue of *Diagnostic Immunology* (DI), is probably a real one.

Unfortunately, little of the content of the first four issues of DI concerns current clinical practice. Although the pitch is often research-and-development orientated, much of this material compares unfavourably with papers appearing in the well-established *Journal of Immunological Methods*. Two useful reviews have appeared on clinical applications of FACS techniques and immunodiagnosis in protozoan and helminthic infections, but there has been little discussion of the practical value of existing methods and ways of delivering a clinical immunology service. Where are the critiques which review how to diagnose and monitor those disorders falling within the prime areas of clinical immunology, i.e. allergy, autoimmunity, immunodeficiency, lympho-proliferative disease and transplantation? The aim to provide "critical evaluation of reagents, quality assurance, standardization of methods and definition of normal ranges" has not been fulfilled. The emphasis of the third issue is on the "goal of providing a forum for discussion of new and promising methodologies", whereas the fifth issue (Vol. 2, No. 1) is the first one to contain a reasonable sprinkling of clinically relevant papers.

To me it seems that DI has undergone an identity crisis. Consistency of content, style and production are important prerequisites, if it is to succeed. □

Gordon Reeves is Consultant Immunologist and Senior Lecturer at the University Hospital, Queen's Medical Centre, Nottingham.

Delving inside the cell

L.G. Lajtha

Cell Biochemistry and Function.
Editor E.M. Crook.
Butterworth. 4/yr. Subscription rates for 1985 not available.

THE admirable editorial in the first issue of *Cell Biochemistry and Function* (CBF) indicates such a wide scope that it is difficult to say what precise niche the journal is attempting to fill. The aim appears to be to cater for studies of a biochemical nature on intact, whole cells. Certainly, although it is not specifically stated, the editors are obviously aware of the current emphasis on compartmental studies and of the biochemical challenges to be found in intracellular micromilieux and microanatomical structures.

An especially useful feature is the commissioned reviews, particularly the multi-authored ones which tackle a particular subject (for instance the five-paper review of mammalian alkaline phosphatase). Also included are short communications, full-length papers (with laudably detailed abstracts), conference reports, calendars of meetings, book reviews and, at the end of each volume, author and subject indexes.

The journal is nicely designed and produced — I particularly like the double-column presentation — but while the paper is of good quality, it does not give as much contrast to electron micrographs as one would like. It is truly an international publication, the papers coming from respectable laboratories all over the world, and the standard of contributions is high, both in science and in writing; the declared rights of the editor to make such editorial amendments as are deemed necessary does result in a pleasant uniformity and clarity of style.

CELL
BIOCHEMISTRY
AND FUNCTION

I think that CBF will appeal to a wide range of readers, although for four issues of about 65 pages each the subscription (£80 in 1984) is on the expensive side. The journal is a sound vehicle for studies of modern intracellular biochemistry and I suspect it will not remain a quarterly for long. ☐

L.G. Lajtha is Emeritus Professor of Experimental Oncology, University of Manchester.

Thinking small

Richard W. Lacey

Journal of Microbiological Methods.
Editor-in-chief D.C. White.
Elsevier Biomedical. 12/yr. Dfl. 510.
Diagnostic Microbiology and Infectious Disease.
Editor-in-chief William J. Martin.
Elsevier Biomedical. 4/yr. $132.

LIKE the cultures which so many of them discuss, journals on microbiological matters are proliferating. Do these two new contenders give readers (and authors) good value?

Each issue of the *Journal of Microbiological Methods* (JMM) contains about six substantial papers on aspects of the physiology, ecology and pathogenicity of bacteria (rather than of any other microorganism). While the science is sound, most of the methods reported are specialized in scope and will appeal largely to workers in each specific field; so while libraries should stock the journal, there will be few individual subscribers. The text is readable — presumably reflecting high editorial standards — and the presentation is good; indeed it is not unlike that of the *Journal of General Microbiology*, to which some of the papers might have found their way. On the debit side, the photographs could perhaps be improved, and I wonder whether enough experimental details are given for the non-expert worker trying to reproduce the experiments.

To date most papers have been published within a few months of acceptance, but quite a number suffered delays due to revision. Was this because authors were not familiar with the journal's style, or did the editors demand improvements in presentation or in scientific content? Whatever the case, prospective authors would certainly not jeopardize their reputation by publication here.

I can be less positive about the stablemate of JMM, *Diagnostic Microbiology and Infectious Disease* (DMID). Each issue contains about eight full-length papers with a variable number of shorter contributions. Most papers are published within six months of receipt, although here, too, many were revised. The standard of detailed editing seems to be high, and the presentation is again good.

The scientific content, however, is variable. The first issue of the journal (March 1983) contains a number of papers commenting on the antibacterial activity and sensitivity-testing of new antibiotics in arbitrary and uncritical ways. In them the objective in the synthesis of new antibiotics is apparently seen to be the identification of an agent with the broadest spectrum and lowest minimum inhibitory concentration. But surely the object of diagnostic microbiology should be rapid and accurate diagnosis, enabling the use of antibiotics wth minimum selection pressure?

Contributions in later issues of DMID do fortunately manifest such an approach. Some of them could have been published in the *Journal of Infectious Disease*, and are of almost comparable standard, but it is difficult to see reasons for some work being undertaken, let alone published. For example, a paper in the January 1984 issue deals with *Pheumocystis carinii* infection in germ-free rats, concluding that "These data have significant implications for the natural history, diagnosis and epidemiology of *P. carinii* with regard to the human host". Such a comment is extremely disturbing, when it is appreciated how much the disease and therapy differ between the rodent and human being.

DIAGNOSTIC
MICROBIOLOGY
AND INFECTIOUS
DISEASE

The journal seeks publications from clinical microbiologists and infectious disease specialists, but I remain unconvinced that members of either of these groups should deflect their energies in this direction, particularly at the expense of their clinical work. How many of our nosocomial infection problems are generated by neglect? Does our interest in novel antibiotics provide the need for these agents? ☐

Richard W. Lacey is a Professor in the Department of Microbiology, University of Leeds.

"THE TRUTH"
THE
ATOMIC COMPLEX
by BERTRAND GOLDSCHMIDT
An accurate, complete and fascinating worldwide political history and personal memoir of nuclear energy — from the development of the bomb in World War II to today's nuclear energy complex and proliferation problems.
NUCLEAR TODAY
Goldschmidt, a leading French scientist turned international statesman, reviews half a century of political moves, countermoves, international intrigue and manipulation. *The Atomic Complex* is a pragmatic look at the nuclear world today, carefully examining the terror nuclear weapons represent, but at the same time stressing the benefits of nuclear energy.

One of the places to get together

O.H. Petersen

Clinical Physiology and Biochemistry.
Editors-in-chief J. Rosenthal and M. Rafelson.
Karger. 6/yr. DM 290, $110.

AFTER a long time of ever-increasing specialization, resulting in smaller and smaller branches on the physiology tree, we now seem to have entered a period of reunification. One of the stated aims of *Clinical Physiology and Biochemistry* (CPB), "designed to provide a vehicle for scientific communications amongst clinicians, physiologists and biochemists", is "to re-emphasize those areas of common biologic interest that already exist". To some extent therefore it will be in competition with the older physiological journals, established before the fragmentation of the subject became a problem, of which at least *Pflügers Archiv* and the *Quarterly Journal of Experimental Physiology* deliberately take a broad view of physiology and include pathophysiological papers as long as they serve the purposes of the subject as a basic science.

Clinical Physiology and Biochemistry

Many of the papers so far published in CPB could, at least as far as the subject matter is concerned, have appeared in any of a number of physiological or biochemical journals. These papers are of a reasonable standard without being overexciting — as usual with a new journal only time will tell if it will be possible to attract really high-quality papers away from the broad-based journals covering the whole range of the physiological sciences, or from the journals covering the interface between the basic sciences and clinical investigations (such as the very successful *Journal of Clinical Investigation*), as well as from the many good multidisciplinary "systems" journals.

The editorial board appears to be somewhat narrowly based as an almost exclusive American-German enterprise, but CPB is the official journal of the National Academy of Clinical Biochemistry and presumably has a reasonably secure financial position. Only original papers are considered and there appears to be no wish to publish letters or notes. The delay from manuscript submission to publication seems long, particularly for a new journal; thus most of the papers in the July-August 1984 issue were received in August-September 1983. The quality of the production is good with figures of uniform standard and the text set out in the now-usual two-column format.

The journal faces tough competition from a number of very different but well entrenched rivals. It will undoubtedly, as stated in the first editorial, serve as *a* forum to foster interdisciplinary exchange of information and concepts, but I am not so sure that it will become *the* major platform for this important exercise. □

O.H. Petersen is George Holt Professor of Physiology at the University of Liverpool.

Infant alternatives

W.D.M. Paton

ATLA (Alternatives to Laboratory Animals).
Editors Michael Balls, Rosemary Riddell and Alastair Worden.
FRAME, 5b The Poultry, Bank Place, Nottingham NG1 2JR, UK. 4/yr. £16.

ALTHOUGH labelled Volume 11, the issues of ATLA on which this review is based are indeed the manifestation of a new journal. The original venture, *ATLA Abstracts*, born in 1973, was not a success, probably because it was competing with more professional abstracting services, and perhaps also because it underestimated the extent to which biomedical scientists were already using non-animal methods. But the new journal, backed by an excellent editorial board, is a different proposition. Its policy (outlined in the first issue) remains that of its parent body, the Fund for the Replacement of Animals in Medical Experiments; but instead of abstracts, it includes research papers, general articles, correspondence, news, book reviews, and a list of titles covering all aspects of alternatives to laboratory animals in biomedical research and toxicity testing.

Will the new journal find a niche? It deserves a chance. The news items are really valuable; nowhere else does one find, for instance, rational analysis of animal experiments from around the world, or compact accounts of the innumerable meetings now taking place. The research papers are mixed: some would hardly be published elsewhere, some are worthwhile. Although they would overlap with other journals, why not have a special place where (say) toxicity tests deliberately shaped to reduce animal use can readily be found? It is up to the editors to ensure the merit of such contributions, the only ultimate guarantee of their being read. The correspondence and book reviews could be equally useful. By contrast the melancholy, unorganized caravanserai of selected titles at the end of each issue seems useless; but again, if classified by technique, substance tested or general topic, with an author index, such a list could also be helpful.

The main difficulty for the journal however, may be strategic. One gets the sense of a battle being fought on two fronts: on the one hand a liking for verbal fisticuffs with the biomedical "establishment", of a type perhaps needful to retain support from the more anti-experiment clientele of FRAME; on the other a genuine scientific and critical approach to research, of the type winning respect from the investigator. Fisticuffs are quite fun, and rather encouraged these days, but are boring to re-read and do not wear well (except in the hands of a Housman, Leavis or Medawar). Dr Balls and his colleagues have a tricky task in child-rearing: one hopes that it is an occasional gentle irony (a tutorial with Lewis Thomas would do) along with some meat that finally clothes this promising infant. □

Sir William Paton retires this month as Professor of Pharmacology, University of Oxford.

Science at play

E.C. Frederick

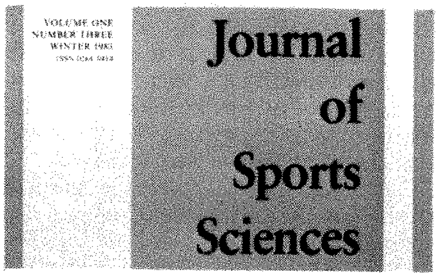
Journal of Sports Sciences.
Editor Thomas Reilly.
E. & F.N. Spon. 3/yr. £39.50, $84.50.
Sports Medicine.
Editor-in-chief Rennie C. Heel.
ADIS Press, PO Box 34-030, Birkenhead, Auckland 10, New Zealand. 6/yr. $95, SwFr. 210.

PUBLISHERS have responded slowly to the furious growth in sports science over the past decade. At a time when the number of researchers was doubling and tripling, the number of journal pages expanded in slow motion. As a consequence, long publication delays and abnormally high rejection rates became the norm.

Although some of the pressure was relieved by the introduction in 1980 of the *International Journal of Sports Medicine*, and by modest increases in issue size and frequency by many existing journals, it was not until the recent spate of new journals that sports science researchers finally found some breathing room. Two contenders for our papers and our subscriptions that should be mentioned in passing are the *International Journal of Sports Biomechanics* (which has just released its first issue and so it is too soon to gauge its scholarly impact), and *Human Movement Science*. The latter espouses an editorial policy encompassing most of the constituent disciplines of sports science, but up to this point has largely published motor-learning papers of somewhat specialist appeal.

The two newcomers that deserve more detailed description, and are reviewed here, are the *Journal of Sports Sciences* (JSS) and *Sports Medicine* (SM). The editors of JSS have shaped their journal into a broadly based, multidisciplinary publication of consistently high standard. Each of the first four issues contains five to six full-length articles, mainly research reports, and an occasional review. In addition, book reviews and a comprehensive listing of forthcoming events appear at the end of each issue. Abstracts from the meetings of the Society of Sports Sciences, the journal's sponsoring body, are published at appropriate times.

Thomas Reilly and his colleagues have clearly avoided the danger of their journal becoming a place to recycle problem manuscripts — a pitfall that traps many new journals — and the high rejection ratio of 70% of submitted manuscripts bespeaks the path they have taken to avoid the problem. No indication is given of the time required for review, but the median time from acceptance to publication is a quick two months.



VOLUME ONE
NUMBER THREE
WINTER 1983

Journal of Sports Sciences

In a field of science that is blossoming over such a range of subjects, it can require superhuman dedication to keep track of the trends in areas in which one is not active. *Sports Medicine* helps by publishing six issues annually, each of them containing review articles and "leading articles" which are a forum for the communication of key issues in sports science.

Although the journal's title suggests a clinical emphasis, the term sports medicine is used in a general, multidisciplinary sense; for example, articles in the first three issues cover topics as diverse as ergometry, biological rhythms, sports injury, bicarbonate ingestion, cycling physiology, sex and hereditary effects, and endorphins. The quality and depth of the contributions are uneven, as might be expected given such broad scope, but most are useful and well written.

JSS and SM are welcome additions to an area of science in need of deeper as well as broader journal coverage. These two well-executed newcomers help meet the need on both accounts. ☐

E.C. Frederick is Director of the Nike Sport Research Laboratory, Exeter, New Hampshire.

• A new book of interest to many researchers in sports science is Thomas A. McMahon's *Muscles, Reflexes, and Locomotion.* The book is published by Princeton University Press (price hbk $50, £45.80; pbk $15, £10.70), and will be reviewed in the 11 October issue of *Nature.*

Eye to eyes

George Duncan

Lens Research.
Editor-in-chief Sidney Lerman.
Dekker. 4/yr. $70 (US),
$81 (elsewhere).

Lens Research has been launched upon a stormier sea than are most new journals. Not only do the usual financial stringencies confront it, but the very material that should provide much of the data for the journal — namely, the human lens — is, in many parts of the Western world, removed piecemeal in a messy homogenate rather than as a useful entity. The editor, however, takes a sanguine view of the latter difficulty and believes that it will lead to a rapid improvement in the range of *in vivo* techniques available for lens investigation.

The journal is produced by photo-offset and aimed at the rapid-publication market. It has a distinguished editorial board to steer it, and to set the tone many of them contributed to the first issue. The articles, all derived from a symposium held in Eindhoven in October 1982, are interesting and well produced. They deal with topics as diverse, but equally important, as the X-ray crystallographic structure of lens crystallins and the *in vivo* measurement of light-scattering from human lenses. However, a high proportion of the illustrations (I estimate almost 20%) in this issue were reproduced from previous publications. This is an unwarranted intrusion in the first number of any journal, let alone one which purports to cater for the rapid publication market. (At present, it is in fact impossible to judge how quickly the submitted word is converted to the printed page, since neither submission nor acceptance dates are given in any of the issues so far produced.)

The production standard of the journal had slipped badly by the time the third issue appeared, since one article was published with an average print density of 6 words per line and 22 lines per page. I leave the reader to total up this page for comparison. Another article was photo-offset directly from a low-density dot matrix print-out; apart from contravening the published house rules for submission of articles, it was extremely difficult to read — a great pity in this particular case, since the paper described a good study carried out on those precious intact human cataractous lenses.

One most excellent feature of the journal was the inclusion of a comprehensive index at the end of the third issue. If this sort of care could be extended to the production side, and allowance made for comments on previously published articles, then it might be possible to foresee a calm and fruitful voyage ahead for this particular lens flagship. ☐

George Duncan is Reader in Biophysics at the University of East Anglia.

Between two cultures

John Yudkin

Nutrition and Behavior.
Editor Robin B. Kanarek.
Alan R. Liss. 4/yr. $35 (personal);
$70 (institutional).

IT IS only recently that the traditional nutritionist, concerned with the isolation and description of the nutrients and their effects, began to recognize that the true scope of nutrition embraces the total relationship between people and their food. The subject is therefore based as much on the behavioural sciences as on the experimental sciences. The established journals of nutrition have started to reflect this by publishing occasional papers concerning such matters as food choice and nutrition education. Now comes *Nutrition and Behavior,* devoted wholly to such matters, with papers dealing with the effects of nutritional status on learning, memory and food choice, as well as with the effects of behaviour on nutrition.

A major problem is that those working in the laboratory sciences and those working in the behavioural sciences have developed attitudes and concepts that are often difficult to reconcile. The first paper published in the first number of this new journal illustrates the point. Examining the relationship in children (aged from 5 to 16) between refined carbohydrate intake, hair cadmium and cognition, the authors measure food intake by the totally inadequate method of 24-hour recall. They also ignore the frequent demonstration by laboratory workers that hair analysis for mineral elements is quite unreliable. The tables and figures accompanying the paper contain no recognizable data such as the number of grams of carbohydrate and protein in the diet, or the scores of some of the intelligence tests, but are all derived after one or more mathematical transformations.

Later papers published in the four numbers of Vol. 1 of the journal will not be found so frustratingly incomprehensible; perhaps we can now expect the editors to be more critical of what is submitted to them. There is no point in providing a journal that, as they claim, is aimed at "interdisciplinary communication to researchers in a variety of fields" if what is published fails to communicate anything to most of its readers. Yet, if the journal does fulfil its promise, it will be an important contribution to the literature of nutrition.

John Yudkin is Emeritus Professor of Nutrition in the University of London.

Divers advisers

Stuart Sutherland

New Ideas in Psychology: An International Journal of Innovative Theory in Psychology.
Editors Pierre Moessinger, John Broughton and Richard Kitchener.
Pergamon. 3/yr. £46, $80.

PSYCHOLOGY is becoming a spectator sport. From the terraces a motley crowd of philosophers, linguists, sociologists, anthropologists and artificial intelligencers heckle, cheer and boo. But above all they proffer advice.

The first four issues of *New Ideas in Psychology* (NIP) contain a good many papers of this kind. Some authors advise psychologists to revert to teleological explanations, others urge them to seek salvation in artificial intelligence. Yet others recommend speculative theories provided they are testable, while perhaps the most original piece of advice is contained in a paper which advocates the founding of a science of happiness, to be known as eudology.

Almost all the papers are followed by commentaries, a format that increases the interest of NIP, which is nothing if not eclectic. There are papers on such disparate topics as chimpanzee language, brief psychoanalytic therapy, personal construct theory and the existence of paranormal phenomena, and there is a solitary experimental report that suggests laughing gas operates through the orbital frontal cortex.

Although there is room for a psychological journal of speculation, one wonders whether the fields covered by NIP are not too diverse. Moreover, the quality of the contributions is a little uneven and one commentator's remarks on an article apply to several. He writes,

> Like most programmatic manifestoes it serves the socio-psychological purpose of alerting like-minded scholars to the existence of a community of concern, but it fails to show signs of that rigor of analysis and systematic coverage of the subject matter that the author claims must distinguish a science.

The journal should provide an outlet for articles of this kind and will therefore doubtless serve an important "socio-psychological purpose". □

Stuart Sutherland is Director of the Centre for Research on Perception and Cognition, University of Sussex.

Split psychology

Geoffrey Hall

Journal of Comparative Psychology.
Editor Jerry Hirsch.
American Psychological Association.
4/yr. $36 (US), $39 (elsewhere).
Behavioral Neuroscience.
Editor Richard F. Thompson.
American Psychological Association.
6/yr. $100 (US), $103 (elsewhere).

THE influence of the American Psychological Association is such that when it decides to reorganize its journals the international psychological community has to take notice. If a shift in policy does not reflect a change of emphasis in work in psychology, then it seems probable that one will result.

These two "new" journals are the fission products of the demise of the old *Journal of Comparative and Physiological Psychology* (JCPP) which existed from 1947 to 1982 as the continuation of an earlier (1921-1946) *Journal of Comparative Psychology* (JCP). The original JCP attempted to cover all aspects of the behaviour of non-human animals; its change of title recognized that physiological studies (of brain lesions and, latterly, of the effects of drugs) had come to predominate. When, in 1975, the other main line of work covered by JCPP (laboratory studies of conditioning and learning) was hived off as a special section of the *Journal of Experimental Psychology*, a reconsideration seemed appropriate. What we have now been given in *Behavioral Neuroscience* is a journal devoted to "the broad field of biological bases of behavior" whereas the new version of JCP is concerned with "behavioral patterns... as they relate to evolution, development... and functional significance".

Contributors to a recent symposium on "the place of physiological psychology" saw in this split evidence of an identity crisis in their discipline. But in fact *Behavioral Neuroscience* with its sophisticated behavioural analyses of the effects of lesions and of drugs looks like a direct continuation of JCPP. The work reported is first-rate and this journal will retain its predecessor's reputation as being foremost in its field. JCP is something rather new but seems set to establish itself as a direct competitor to the respected ethological journal *Animal Behaviour*. Given the recent upsurge of interest in North America in what is sometimes called the "ecological" approach to animal behaviour, there is much good work to report and plenty of room for both journals.

These various divisions seem to follow natural fracture lines and are a sensible reaction to the growth of the field. Nonetheless, one looks back on the original JCP with a tinge of regret — ethologists have things of interest to say to learning theorists and both should communicate with physiological psychologists; it would be a pity if any new journal structure were to make such interactions less likely. □

Nervous beginnings

A.G.E. Pearse

Neurochemical Pathology.
Editor-in-chief Lloyd A. Horrocks.
Humana. 4/yr. $100.

CHEMICAL pathology, a term once popular, now has a decidedly antediluvian flavour, following absorption of the subject into clinical biochemistry. So what *is* neurochemical pathology except neuropathology in modern guise?

It comes as no surprise to learn that that is apparently just what the editors of this journal intended. According to their stated terms of reference, the journal is to "serve as the key forum for studies in the rapidly expanding area of biochemical neuropathology" and it "will thus be predominantly devoted to biochemical studies on all those tissues or body fluids that may help to elucidate the etiology or pathogenesis of neurological disorders".

Neurochemical Pathology is sponsored by the International Society for Neurochemistry and the World Federation of Neurology Research Groups on Neurochemistry and Cerebrospinal Fluid. I recognize, on the editorial board, many names derived from these two sources but I doubt if all were consulted in the matter of the creation of the new journal.

It may be pertinent to enquire, in so far as the first volume is concerned, just how far the editors have succeeded in their reasonably justifiable aims. There are 21 papers in the four numbers comprising the volume, and of these no less than 14 come into the category of experimental neuropathology. There are three purely neurochemical papers, each of which contains only a hint of future pathological importance, and three further papers describing chemical aspects of known, little known or unknown syndromes. The one remaining paper is an exercise in clinical neurochemistry.

With so great a preponderance of reports on experimental work — and despite the fact that much of it has some relevance, at least, to deficiencies or overdosages potentially occurring in human beings — one wonders whether the word "experimental" should not have been included in the journal's title. But it is clear enough that the editors did not intend their first year's coverage to present to the reader this predominantly experimental front, nor the virtual exclusion of several of their specifically cited areas of interest.

I conclude that several more years (more volumes) will require surveyance before it is possible to reach a positive conclusion that this journal is a useful one. Sad to say, with its present format and content it fails to justify its existence at all. □

Anthony Pearse is Professor Emeritus of Histochemistry in the University of London.

Society's slice of neuroscience

R. Victoria Stirling

International Journal of Developmental Neuroscience.
Editors-in-chief Antonia Vernadakis and Ezio Giacobini.
Pergamon. 6/yr. £86, $150.

At its annual general meeting in 1983, the International Society for Developmental Neuroscience decided to break an affiliation with Karger, the publishers of *Developmental Neuroscience* (reviewed in *Nature* **293**, 347; 1981), on the grounds of lack of copyright control, excessive page charges, long publication delays and poor illustrations. The new deal with Pergamon, who publish the *International Journal of Developmental Neuroscience* (IJDN) with the same editors-in-chief, seems much more advantageous. Subscription to the Society includes subscription to the journal, and the publisher also prints and distributes the Society's newsletter and collects membership dues. Members are exhorted to contribute to the new journal, the success of which should also accrue to the Society.

The instructions to authors are remarkably similar to those of *Neuroscience* (another society journal, under the editorial board of the International Brain Research Organization). But while the list of editors of IJDN spans many parts of the world, of 33 papers in four issues over half are from the United States, with a quarter from Europe, three from Asia and one each from Venezuela and Finland (i.e. less cosmopolitan a range than *Neuroscience*). In the first issue of Vol. 2 are published an impressive series of abstracts from the Fourth International Congress held in Utah in 1983. I could find only one author who also contributed a paper to IJDN. Most of the contributions to the journal are biochemical in nature, very few being concerned with structural aspects of development. It is therefore difficult to judge the quality of photographic reproduction, but it seems reasonable.

The delay in publication appears to be about six to seven months, though at the start of Vol. 2, the editors announced that to ensure a prompt service they had appointed associate editors in Venezuela and Japan; this was a good idea though the efficiency of the arrangement has yet to manifest itself. Apart from the minutes of the annual general meeting there is no editorial comment, although such a feature (and book reviews) had been suggested at the meeting.

INTERNATIONAL JOURNAL OF
DEVELOPMENTAL
NEUROSCIENCE

This slim journal may potentially be a very useful publication for members of the Society. But unless they contribute meatier material, I cannot see it taking a larger slice of what is now a dwindling cake. ☐

R. Victoria Stirling is a member of the scientific staff at the National Institute for Medical Research, London.

Trends in the risk business

J.R. Ravetz

Risk Analysis: An International Journal.
Editor-in-chief Curtis Travis.
Plenum. 4/yr. $90 (US), $101 (elsewhere).

THE journal *Risk Analysis*, published by the Society for Risk Analysis, reflects the diversity of effort in this area, and also the history of the dominant trends. The attempts at "scientific" studies designed to determine the acceptability of technological risks began in earnest with a classic paper by Chauncey Starr in 1969. The failure of such attempts, first to model "low probability/high cost" hazards, and then also to quantify "acceptability", led to enrichment of the programme by behavioural studies during the 1970s.

The Society was formed rather late in the day, and in its earlier issues the journal still concentrated on a scientistic approach. However, controversy soon broke out in its pages; broader appreciation of the technological and environmental issues found expression in an increasing proportion of its contents. The founding editor, Robert Cumming, contributed to this development by his policy of soliciting articles and insightful editorials.

By now the journal presents a lively picture of current work, all the major articles being accompanied by invited critical comments. For instance, it has recently been the publication point for a seminal paper by Alice S. Whittemore, "Facts and Values in Risk Analysis for Environmental Toxicants" (Vol. 3, No. 1; 1983). In this, it becomes clear that a new methodology, involving the complementarity of "facts and values" and of "knowledge and ignorance", is necessary if an effective discipline of risk analysis is to emerge. ☐

Risk Analysis

J.R. Ravetz is a Senior Fellow at Leeds University, and Co-Director of the SERC-ESRC "Risks" project.

Developing forms of energy

Gordon MacKerron

Renewable Sources of Energy: An International Journal.
Editor-in-chief Essam El-Hinnawi.
Tycooly International, 6 Crofton Terrace, Dun Laoghaire, Co. Dublin, Ireland. 4/yr. Subscription rates for 1985 not available.

ENERGY politics, and therefore energy studies, are bedevilled by an analytically damaging dichotomy between non-renewable and renewable sources. The split will, however, persist, and the latter have generally been served poorly. So there is a real need for a journal devoted to the renewables.

The principal aim of *Renewable Sources of Energy* (RSE) is to "facilitate the flow of information between developed and developing countries", with emphasis on the requirements of developing countries. While the central concern is ostensibly with energy technology, the journal contains a great deal on policy matters, particularly environmental control and local planning. In comparable existing journals (for example *Energy Policy* and *Energy: An International Journal*) renewables have received only sporadic coverage, while among publications dealing specifically with renewables, *Solar Energy* is narrower and more technical, and *World Solar Markets* and *Soft Energy Notes* are less academic. The focus of RSE is therefore unique.

The length of papers published to date has varied between 3 and 28 pages, each issue containing about 6 articles. There are, as yet, no editorials or comments on earlier papers, and only a rather perfunctory review section divided between "News and Views" and some short book reviews.

Articles generally fall into one of two types: semi-technical reportage of devices and projects (for example design optimization of solar water heaters; experience of a rural energy centre) and broader reviews covering such topics as geothermal energy or energy and community development in developing countries. The quality of the former is reasonably good, while that of the reviews is poorer, with some lapses into pious generalities.

Reflecting the editorial objectives, RSE's authorship is centred upon the developing countries, with a third of the early papers coming from India (and one welcome Chinese contribution). The main requirement in this field is for communication between developing countries and this journal should help to provide it. ☐

Gordon MacKerron is a Senior Fellow in the Energy Programme, Science Policy Research Unit, University of Sussex.

Water works

T.R. Parsons

Continental Shelf Research.
Editors Michael Collins and Richard W. Sternberg.
Pergamon. 6/yr. £63, $110.
Chinese Journal of Oceanology and Limnology.
Editor-in-chief C.K. Tseng.
Science Press, Beijing/Springer-Verlag. 2/yr. DM73, $33.

TWENTY-FIVE years ago, oceanographers learned the terms "oceanic" and "neritic" with their vague implication of a discontinuity between plankton species (and therefore, presumably, the physical–chemical environment of the sea) as one approaches a coastline. Not until the past decade, however, has a general understanding emerged of the distinct oceanographic changes which occur as water flows over the continental shelf. Thus I am in complete agreement with Dr Sternberg's statement that research in this area has "come of age", and it is now helpful to think of many oceanographic processes as being either deep-sea or continental shelf phenomena. This is the rationale behind the appearance of *Continental Shelf Research* (CSR), which complements the longer-established journal *Deep-Sea Research.*

The new journal is interdisciplinary in aims and promises to meet a number of needs for oceanographers working on this specialized and, at times, highly variable environment. The first three volumes have contained a wide variety of papers on water movement, frontal zones, microbiology and geological processes. Although in the editorial policy it is not stated that the journal specifically excludes articles on pollution, the early issues are refreshingly devoted to what I would call the pure science of the oceans — studies on the use of the continental shelf as a dumping ground seem either not to have been submitted to date, or to have been excluded. The journal also contains short sections on instruments and methods, and book reviews. Written comments on papers will be considered for publication up to three months after the appearance of the original paper.

There are no Japanese oceanographers on the editorial advisory board and, in fact, one gains an impression from the choice of the associate editors that much of CSR may be given over to discussion of the margins of the Atlantic Ocean. To fulfil the avowed role of a "platform for international research programmes", the editors should have selected their assistants from a wider constituency. On the other hand, the interdisciplinary nature of the subject is reflected both by the composition of the editorial board and by the articles published so far. Clearly CSR has made a good beginning. It should go on to become essential reading for oceanographers.

The Chinese-language journal *Oceanologia et Limnologia Sinica* was first published in 1957 and, by 1982, 410 articles on limnology and oceanology in China had appeared. The other journal reviewed here, the *Chinese Journal of Oceanology and Limnology* (CJOL) is not, as might be thought, a full translation of the Chinese journal. Authors who write in *Oceanologia et Limnologia Sinica* may have their work translated for publication in CJOL, but the journal will also accept articles from other Chinese-language publications as well as original papers written in Chinese. This, then, is how a country of one billion inhabitants and many new institutes of limnology and oceanology intends to present a representative sample of its science on these subjects to the English-speaking world.

Out of the first 23 articles published by CJOL, seven were concerned with physics, six with chemistry, two with geological processes and eight with biology; only two of these papers were limnological in nature. Geographically, most of the authors dealt with scientific problems within China, but one paper was concerned with the Tyne estuary in England.

The papers in physical oceanography do represent an up-to-date approach to the subject. The biological contributions, on the other hand, are mainly keyed to systematics and there is as yet little indication of biological modelling or of more broadly based studies on descriptive ecology. In attempting to carry out their intention of covering a wide spectrum of aquatic science in China, the editors may have gone too far by including at least one paper in the first two numbers which is entirely physiological, while Part II of a paper in physics is promised for another issue — a promise which may be difficult to keep, given the vast amount of Chinese-language science which has to compete for space in the journal.

CHINESE JOURNAL
OF OCEANOLOGY AND LIMNOLOGY
中国海洋湖沼学报

In general, however, Professor Tseng and his colleagues have performed a necessary task in exposing Chinese limnology and oceanology to a wider audience. The journal is well produced, and the text gives little indication that it has been translated. But I have one plea. The editors should ensure that the location of each of the studies is identified. In many of the articles it is not; one example is the paper on the tidal equilibrium of Blue Bay — where in the world is Blue Bay? ☐

T.R. Parsons is a Professor in the Department of Oceanography at the University of British Columbia, Vancouver.

NEW from The Institute of Physics

Inverse Problems

An International Journal on Inverse Problems, Inverse Methods and Computerised Inversion of Data

Editor: P C Sabatier *(Université des Sciences et Techniques du Languedoc, Montpellier, France)*

Inverse Problems will report current research work in this active and expanding field of research and will be of interest particularly to physicists and pure and applied mathematicians, as both contributors and readers. The results of this research are relevant to practitioners in seismology and prospecting, particle scattering, pattern recognition, radar imaging and the many other fields where maximum information needs to be extracted from experimental results.

1985 Vol 1 4 issues £105

Classical and Quantum Gravity

An International Journal of Gravity
Geometry of Field Theories Supergravity Cosmology

Editor: M A H MacCullum *(Queen Mary College, London)*

Launched in 1984, *Classical and Quantum Gravity* reflects current work with implications ranging from particle physics to cosmology, and is aimed at theoretical physicists, mathematicians and cosmologists working in all branches of the theory of space—time and gravitation.

1985 Vol 2 6 issues £95

Geophysics: ins and outs of the library

Jean-Claude De Bremaecker

Annales Geophysicae. Editor-in-chief Stephan Mueller.
Gauthier-Villars, 11 rue Gossin, F-92543 Montrouge Cedex, France.
6/yr. FF780.
First Break. Editor Ian Williamson.
Blackwell Scientific. 12/yr. £34.50, $58.

GEOPHYSICALLY, Europe is slowly emerging from the deep: she wears a Latin dress but speaks English. At least, so it seems, for *Annales Geophysicae* (AG) has replaced both the French *Annales de Géophysique* and the Italian *Annali di Geofisica.*

As the official journal of the European Geophysical Society, the future of the journal is promising. It embraces the same subjects as its well-known American counterpart, the *Journal of Geophysical Research*; that is, all the fields covered by the International Union of Geodesy and Geophysics, but with one confusing exception: geochemistry and volcanology are not mentioned in the "scope of the journal". It appears that geodesy may also be excluded, but this is less certain. Further to confuse matters, the president of the EGS states in the first issue that volcanology and geochemistry as well as geodesy are *included.* The "scope" appears inside the front cover, the president's words on the facing right-hand page, and never have the twain met.

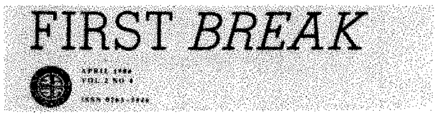
One presumes that all articles are refereed, and very speedily too, since the average delay for acceptance is about two months. The editorial board is made up exclusively of western European geophysicists, and very few contributors come from eastern Europe either, a geographical bias which should be corrected. The articles are of a remarkably high quality for a new publication, the abstracts not always so. Thirty-three years have passed since Kenneth Landes's classical "Scrutiny of the Abstract" (*Bull. Am. Ass. petrol. Geol.* **35**, 1660) yet still one finds that "The theory...is developed. An algorithm ... is proposed. Examples...are presented. The possibility of application...is discussed". It seems only reasonable to hope that the editors will in future demand abstracts that are, in Landes's words, "a condensation of the essential qualities of the paper" and "not a mere recital of the subjects covered".

English, we all know, is a good simple international language (except for its spelling). As a non-native speaker residing in the United States, I particularly appreciate the problems which AG's authors and editors have faced and generally overcome. A simple example comes to mind: the French "Pour lever cette difficulté..." does *not* mean "in order to raise the difficulty". There are very few such examples in the journal, and perhaps the best solution to this problem is to forget it; for, as scientists say, "the solution is not entirely clear", which means that it is utterly obscure.

One attractive feature of AG is the absence of page charges, coupled with the supply of 50 free reprints. The format (two-column on approximately 21 × 30 cm paper) is open and pleasant, the printing is of high quality, while the style and typography for the references are the best that I have ever come across. Much as in the *Journal of Geophysical Research*, only articles are published, but short notes are also welcome. So far no "comments" on previously published papers have appeared; presumably they will, eventually. Overall, at a subscription price of FF780 (*c.* $84) outside France, this is a bargain that libraries should not miss.

First Break (FB) is a different sort of beast. It does not aim at being a scientific journal, instead publishing "short non-technical articles...and up-to-date news about the geophysics industry". It is thus not meant to be archived, but does fill a clear need by offering executives and others in the oil industry a means of keeping abreast of events. The industry news consists mostly of publicity releases, and has to be read with a dose of scepticism — that does not make it less valuable. It thus goes without saying that few libraries will want to subscribe to FB, which is to the good of everybody concerned.

The editor is to be commended for dealing exclusively with items connected with geophysics. This may seem obvious, but it is not. Only a little while back its counterpart in the United States, *The Leading Edge,* was launched and unwisely included anything of conceivable interest to geophysicists. As a result its first numbers contained a mish-mash of right-wing propaganda, cross-word puzzles and sports news, with a dash of geophysics added for good measure. *First Break,* it seems, has profited from that sad example.



A common temptation with a publication such as this is for the publishers to try to "upgrade" it to a *bona fide* scientific journal. This shoal has not been avoided entirely by FB: at least one paper is reproduced from a well-known geophysical journal. Worse yet would be to fall to the level of taking non-refereed papers which have not been accepted (and could not be) by established journals — far better to publish a slimmer issue than one containing second-rate material. One can only hope that the editor will keep his goal firmly in mind over the next few years; some of the papers are a little disquieting in this respect.

First Break is a readable, informative and reasonably cheap publication. But considering the world-wide scope of the geophysics industry and its currently rather depressed state, as well as the thinness of both FB and *The Leading Edge,* I cannot help but wonder whether these two publications should not merge. It might bruise some editorial egos but the readers of both might well be better served. □

Jean-Claude De Bremaecker is a Professor of Geophysics at Rice University, Texas.

Talk of integration and communication

John Tarney

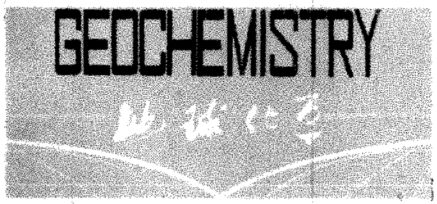
Journal of Metamorphic Geology.
Editors M. Brown, T.P. Loomis and R.H. Vernon.
Blackwell Scientific. 4/yr.
£47, $97.50.
Geochemistry.
Chairman of the editorial committee Tu Guangchi.
Science Press, Beijing/Springer-Verlag.
4/yr. DM 129, $54.50.

IT WOULD not be exaggerating to say that well over half of the Earth's continental crust is composed of metamorphic rocks, so it is surprising that there has been no specific journal acting as a focal point for research in this area. Until now, observational details have been recorded separately in various national and international journals of mineralogy, petrology, geochemistry or structural geology, of which there are now a great many, and this has put limitations on the possibilities for an integrated approach to the subject.

The new *Journal of Metamorphic Geology* (JMG), titled as it is with the broad term "geology" rather than just "petrology" and so on, should provide an appropriate vehicle for the reporting of broader ranging research on metamorphic rocks, although this may be more commonly achieved through the publication of thematic issues. Certainly, detailed integrated studies are now beginning to tell us a great deal about the past thermal and tectonic histories of metamorphic rocks, and the importance of fluids, which may be of great value in attempts to reconstruct the geological evolution of a province in terms, for instance, of plate tectonics.

During its first year, JMG has attracted contributions from an international group of authors on a wide variety of subjects, dealing with rocks from several continents which extend over an age span of 3,000 Myr. Admittedly, with one or two exceptions, most of these articles could have been published in one or other of the established journals without significant modification, so it remains to be seen whether the new journal will develop a character of its own: only time will tell, but the promise is there. The standard of presentation is high, the style conforms fairly closely to that of other journals published by Blackwell, and altogether JMG represents fairly good value for money.

Geochemistry, a Chinese journal which for the past two years has also appeared in an English-language version, is rather different. Of the several dozen articles which have appeared so far, almost all are written by Chinese authors (although one article has a non-Chinese co-author) and they deal almost entirely with Chinese geological and geochemical problems. Clearly, on the one hand, Chinese geochemists have accepted that English has become, for better or worse, the international language in the geosciences; on the other, we see here implicitly their strong desire to participate fully in geochemical research at international level in future.



The range of topics covered is comprehensive — various aspects of igneous, metamorphic and sedimentary rock geochemistry, meteorites, marine geochemistry, economic geology and mineralization, organic geochemistry, isotopic dating, experimental studies and new instrumental techniques — and several articles on crystallography and new minerals have also been included. The scope, then, is wider than that of international geochemical journals, and extends into fields normally covered by journals of mineralogy, petrology and economic geology. The standard of presentation and the scientific content of the articles is generally high.

Now that several Chinese institutes have furnished themselves with a range of advanced geochemical instrumentation, comparable with that of any laboratory in the world, we can look forward to an increasing number of important contributions from Chinese geochemists. If that proves to be the case, *Geochemistry* will become necessary reading for many geoscientists. □

John Tarney is F. W. Bennett Professor of Geology at the University of Leicester.

Heart of Gondwana

Paul Mohr

Journal of African Earth Sciences.
Editor-in-chief Cornelius A. Kògbe.
Pergamon. 4/yr. £49, $90.

AFRICA is no longer "the black continent with the big blank spaces on its map" — the description of Hans Cloos en route to his first employment as a geologist in German West Africa. Africa's geology, mostly the preserve of European explorers before the First World War, has painstakingly become revealed through the work of colonial geological surveys and, especially since 1945, by an enthusiastic influx of European and American university personnel. Most of their work has been published in "international" (i.e. European and North American) journals.

Aside from geological survey reports, not notable as repositories for intellectual discussion and new ideas, the African geological literature has been scant (South Africa providing an outstanding exception). Now there appears the *Journal of African Earth Sciences* (JAES). Although published outside Africa, and with its chief and regional editors likewise resident outside the continent, it makes a bold beginning. African geologists and geophysicists have had increasing need for a publishing forum that transcends national boundaries yet keeps to the heart of Gondwana.

The format of JAES is African in its spaciousness (21 × 30cm), it is well produced (the photographic plates are sharp, the line-drawings large and readable), and the print is a boon to eyes overly strained from reading some established journals. The first volume comprises 37 articles, not including book reviews and conference reports. The quality varies, generally in direct proportion to article length. Interestingly, Nigerian and Egyptian geological topics (there are no geophysical articles in this first volume) together make up more than half the volume. Only five articles deal with Francophone Africa, four of these in French. Southern Africa and Zaire are conspicuously unrepresented. Of the authors, about half are based at African institutions, which is a fair achievement.

Clearly the infant journal has some growing up to do before it can justify its continental scope and ambition. On the other hand, one notes that there is as yet no *Journal of European Earth Sciences*. Here, then, is a medium for the propagation of that natural entity, African earth science, and, more than that, for indigenous African geologists and geophysicists to develop their scientific mettle. On this first showing, JAES promises well and deserves every success. Its cost is not too unreasonable by wealthy European standards, but, ironically, it has priced itself out of the greater part of the African market it is designed to serve. □

Paul Mohr is Professor of Geology in the Department of Geology at University College Galway, Ireland.

Birth in decay

Norman K. Grant

Isotope Geoscience: An International Journal.
Editor-in-chief G. Faure.
Elsevier Scientific. 4/yr. Dfl. 237.

IF the distinction and international character of an editorial board are sufficient to ensure the success of a new journal, *Isotope Geoscience* (IG) should do well. The first six issues suggest that the editorial resources available to the editor-in-chief will lead to the publication of critically reviewed descriptive, theoretical and review papers of an attractively high standard. So far about two-thirds of the articles have been on the systematics of radiogenic isotopes, and about one-third on stable isotopes, the average time from manuscript acceptance to publication in the latest number being six to seven months. Book reviews are also published.

Elsevier has introduced IG into our libraries as a daughter journal to *Chemical Geology*. Whether the newcomer can meet its ambitious goals of fostering "scholarly communication between isotope geoscientists of the world", and "form a bridge" between them and other geoscientists remains to be seen. Isotope geoscientists are not a homogeneous group, and the range of interests which the journal proposes to serve is extremely wide — radiogenic and stable isotope and radiochemical systematics in inorganic and organic terrestrial and extraterrestrial materials.

It could be argued that the most fruitful approach for isotope geoscientists is to communicate first of all with scientists in complementary and converging disciplines. For this reason it seems likely that many of the most influential papers in isotope geoscience will continue to be published in established journals of a more general nature, such as *Contributions to Mineralogy and Petrology*, *Journal of Petrology* and *Earth and Planetary Science Letters*. If IG is read only by specialists its importance will be limited. So, for the time being, my advice to librarians is to place the highest priority on the purchase of the journal only when their institution includes staff actively engaged in isotopic research. □

Norman K. Grant is Professor of Geology at Miami University, Oxford, Ohio.

In the forecasting movement

Chi-Yu King

Earthquake Prediction Research.
Editor Tsuneji Rikitake.
Reidel. 4/yr. Dfl. 90, $36 (personal); Dfl. 180, $72 (institutional).

EARTHQUAKE prediction, the scientific dream once shunned by respectable scientists, has been hotly pursued during the past two decades in such earthquake-prone countries as the USSR, Japan, China and the United States. Because of its interest to the public, and the multi-disciplinary nature of the research effort, many papers on the topic have been presented at a wide variety of scientific and non-scientific meetings, and published in many different journals and reports. Thus the appearance of *Earthquake Prediction Research* (EPR) to serve as a focal point for work on the subject is certainly very welcome.

The journal is published by a Japanese foundation (the Association for the Development of Earthquake Prediction) in cooperation with the Dutch publisher Reidel, with the objective of providing an international medium for original and review papers, reports and other items related to earthquake-prediction research. The editorial board, consisting of most of the current members of the Commission on Earthquake Prediction of the International Association of Seismology and Physics of the Earth's Interior, is strong and internationally well represented.

As of 31 July 1984, five issues of EPR had been published, three of them devoted to a single international symposium. All the issues arrived at our library in Menlo Park much later than scheduled. For example, Vol. 1, No. 1 (1982) and Vol. 2, No. 1 (1983), the last published issue, were received on 1 October 1982 and 9 November 1983, respectively. Thus the speed of publication is significantly less than one might infer from the manuscript receipt dates shown in the individual papers. Writing from personal experience, I submitted a manuscript on 1 November 1982, but was not informed of its acceptance until 9 June 1984.

EPR
EARTHQUAKE PREDICTION RESEARCH Vol.2 No.1 1983
Edited by Tsuneji Rikitake

Published in EPR so far are an introductory editorial, a meeting report and 29 "regular" papers, most of which are seismological (17) and rock-mechanical (9). About half of the papers are not directly relevant to earthquake prediction and could have been published elsewhere. Similarly, the scientific quality of the papers ranges widely, from the mediocre to excellent. Some of the papers (from non-English speaking countries) could have done with additional editorial assistance. The quality of production is very good, comparable to *Pure and Applied Geophysics*, and the cost is reasonable (Vol. 1, which has 391 pages, cost $69 for libraries and $28 for individuals).

Having identified and filled a significant publication gap, EPR has a potential of becoming a fine international journal. Whether it will fulfil its promise depends on the ability of its editorial members to attract and promptly and properly process good, relevant papers from all the different disciplines concerned, including geology, geophysics, geochemistry, hydrology and biology. ☐

Chi-Yu King is a Geophysicist at the US Geological Survey, Menlo Park, California.

Fusion across the fields

G.J. Pert

Laser and Particle Beams: Physics of High Energy Densities.
Editor-in-chief Heinrich Hora.
Cambridge University Press. 4/yr. £50, $135.

IN 1962, the observation of gas breakdown by high-power lasers initiated research into laser-generated plasmas as a possible source of thermonuclear power. However, before the introduction of the concept of near-isentropic compression in 1972 overcame the fundamental limitations, these proposals remained extremely speculative. It was shown that such compression could be generated by the ablation pressure of the blow-off plasma formed by surface heating of a simple deuterium–tritium pellet (sphere or shell). These initial designs have now been shown to be over-simple, in that the nature of the heating process may strongly modify the compression phase, and this problem particularly applies to laser-driven compression. As a result, ion-beam systems have been proposed as alternatives.

Over the past ten years the field has grown considerably, to the extent that probably about a quarter of the fusion effort around the world is now in this direction, and with a commensurate increase not only in number of workers but also in the range of activity. Research in this area now embraces nuclear burn and product studies, hydrodynamics, electromagnetic wave propagation, spectroscopy, and laser construction and design, in addition to the basic plasma physics. The field is thus rooted in several distinct disciplines, which has led to publication of research results in a wide range of journals.

Despite its somewhat misleading title, the object of *Laser and Particle Beams* (LPB) is to serve the inertial fusion and laser-plasma community. Although the creation of yet another contender for our dwindling library budgets may be questioned, this one must be welcomed; it covers a relatively new, multidisciplinary subject which is served by no existing journal.

The new journal is international in character, the editor-in-chief being Australian and the editorial board drawing its members from Britain and the rest of Europe, Russia, the United States and Japan: this same wide distribution is also reflected in the contents. In the first volume, the standard of the papers is generally high, with contributions included or promised from many of the major laboratories, and they cover most of the range of the field. Publication time to date is relatively short (between six and nine months), and the journal is attractively presented, each issue containing 100 pages and about eight papers. No letters or research-notes are included, but there is a useful book review section.

LASER AND PARTICLE BEAMS

The first issues show that LPB has made an encouraging start, but success in the future will depend on the editors' ability to attract the major papers at present published in a variety of specialist journals such as *Physics of Fluids, Journal of Applied Physics* and *Journal of Physics* Parts B and D. This new journal should become required reading for the inertial fusion community, and at its current subscription rate should be within the budget of most libraries. ☐

G.J. Pert is Professor in the Department of Applied Physics at the University of Hull.

Autumn books

Nature's next review supplement is Autumn books, which appears on 15 November. The books to reviewed include:

- *Ideals and Realities*, edited by Z. Hassan and C.H. Lai, a collection of the essays of Abdus Salam.
- *The Limits of Science* by P.B. Medawar.
- *The 4th Dimension: Toward a Geometry of Higher Reality* by Rudy Rucker.
- *The Resourceful Earth*, Julian L. Simon and Herman Kahn's reponse to *Global 2000.*
- *Superforce: The Search for a Grand Unified Theory of Nature* by Paul Davies.
- *From Knowledge to Wisdom: A Revolution in the Aims and Methods of Science* by Nicholas Maxwell.
- The first three volumes in a new series, *Key Environments*, edited by John Treherne.
- *Discoverers of the Lost World*, George Gaylord Simpson's account of palaeontology in South America.

Matter of the fourth state

R.A. Lawes

Plasma Chemistry and Plasma Processing.
Editors Emil Pfender and Stan Veprek.
Plenum. 4/yr. $95 (US), $107 (elsewhere).

Plasma Chemistry and Plasma Processing (PCPP) attempts to cover "the fourth state of matter" — the plasma state — through the publication of research papers and articles on subjects such as plasma physics, fluid dynamics and heat transfer, surface chemistry, materials science and so on. The claim is made that the journal is a major international focal point for the scientific and technical community. It has yet to achieve that status.

The scope of PCPP is very broad and, with only about 20 papers published per annum, there is some evidence of a lack of focus. Viewed from a particular topic, for example plasma technology in microelectronics fabrication, only two or three papers may be of direct interest to an individual reader each year. Thus, for most readers, this journal will be seen as complementary to other, more specific and established publications such as the *Journal of Vacuum Science and Technology.*

The quality of the papers themselves is good, with a strong emphasis on experimental results adequately supported by theory. Their source is world-wide (with a bias towards the United States!) yet firm editorial control has brought all contributions up to a consistent standard. General review papers are avoided and editorial comment is conspicuously absent. There appears to be little encouragement for readers to respond to previously published papers, and this is a failing which the editors would do well to rectify. The quality of production is uniformly excellent with clear text and legible, informative diagrams.

Broadly, PCPP has met most of its objectives as well as can be expected. At an export price of $107 per volume it is probably a little too expensive to reside on personal bookshelves; however, research workers will wish to peruse the contents regularly and should persuade their libraries to take out a subscription. ☐

R.A. Lawes is Head of the SERC Electron Beam Lithography Facility at the Rutherford Appleton Laboratory, Chilton, Oxfordshire.

Mechanics of Materials: An International Journal.
Editors S. Nemat-Nasser and J. Weertman.
North-Holland. 4/yr. Dfl. 252.
Materials Chemistry and Physics: An International Journal.
Editor V. Lorenzelli.
Elsevier Sequoia. 12/yr. SwFr. 470, $224.

FLEDGLING engineers are taught a subject generally misnamed "strength of materials", which is mostly elasticity theory applied to the analysis of loaded components and structures. "Mechanics of materials", a more acceptable term, incorporates some of this, but much else besides: it includes the study of plastic flow, fracture, fatigue, the mechanical characteristics of cracks and other precisely defined defects, the mechanics of powders and other porous media, mechanical anisotropy and more. *Mechanics of Materials* (MM) is also the title of a new journal which has got off to a flying start since its first appearance early in 1982, and now publishes some 400 pages each year. Its subheading specifies that it is a "forum for theoretical, experimental, and field advances in mechanics of flow, fracture, and general constitutive behaviour of geophysical, geotechnical and technological materials".

The geological emphasis thus expressed is consistent with the expertise of one of the editors, Professor Johannes Weertman, who is attached to both the Materials and the Geology Departments at Northwestern University, Illinois (while the co-editor is professor of civil engineering at the same university). Up to now, most of the papers in MM have come from the United States, but there have been a number from elsewhere, notably from the geo-mechanical group in Paris headed by J.-P. Poirier and from M.S. Paterson's geophysics group in Australia.

The contributions tend to be strongly theoretical in slant, sometimes to the point of ultra-abstraction, but there are also a few experimental papers, some dealing with powders and porosity; and one intriguing work is concerned with the theory of the drying (seasoning) of wood, treated formally as a porous capillary body. Major theoretical categories include fracture mechanics and the theory of defect aggregates, dislocations in particular.

The new journal has two principal competitors (leaving out of consideration the various specialized fracture journals): the veteran *Journal of Mechanics and Physics of Solids*, now in its thirty-second volume and publishing about 500 pages per annum, a journal with distinct (British) Cambridge connections, and the newer *Res Mechanica* (subtitled *Structural Mechanics and Materials Science*), now on Vol. 11 and publishing around 1,000 pages each year. Both have a strong mathematical bias, like the new journal, and the coverage of all

MECHANICS OF MATERIALS

three overlaps considerably. Nevertheless, the geological leanings of MM, combined with the high standard of editing, suggest that it will survive even in the face of the excellent standards of its two immediate rivals.

The other journal, *Materials Chemistry and Physics* (MCP), is a re-titled version of *Materials Chemistry*, transferred to a new publisher from January 1983. In spite of the change of name, it still has a strong chemical bias and indeed the best of the many good papers are all chemical. The authors who fill the annual 1,200 pages or so at present are either Europeans (notably from Italy, France, Spain and eastern Europe) or from India. In this the journal differs from its established rivals, *Journal of Materials Science, JMS Letters, Materials Letters, Journal of Physics and Chemistry of Solids, Solid State Communications* (another letters journal) and *Materials Research Bulletin*. All of these, while international, have a strong American component. Further the new journal has a *de facto* emphasis on electrochemistry, especially photoelectrolysis, and also in general a more applied flavour than does *Journal of Physics and Chemistry of Solids*. It has printed a number of valuable reviews, notably one on oxide electrode materials. Authors are invited to produce camera-ready copy once a typescript has been accepted, and many have availed themselves of this privilege if such it is; unfortunately some had no access to electric typewriters, which should surely be a precondition of acceptance of CRC, in courtesy to readers!

As, say, a journal of applied materials chemistry, I believe that MCP will find a permanent niche. But if it seeks to become a broad-spectrum materials journal (which it is not now), it risks becoming submerged by the competition. ☐

Experiments in Fluids: Experimental Methods and their Applications to Fluid Flow.
Editors W. Merzkirch and J.H. Whitelaw.
Springer-Verlag. 6/yr. DM 245, $97.

THE study of theoretical and experimental fluid mechanics relies, as do most fields of science, on the publication in readily available form of good, independent research which has been carefully scrutinized and refereed before reaching print.

For the past 28 years the *Journal of Fluid Mechanics* has been the major forum in this field, and its record has been excellent. Subjects which are embraced by that publication are also among those proposed for this new English-language journal, *Experiments in Fluids* (EF). However, while there is merit in a new journal specifically dealing with experimental fluid mechanics, it would be regrettable if the *Journal of Fluid Mechanics* was thereby to reduce proportionally its number of papers on this important part of the subject; it would appear that there are enough acceptable papers to fill both journals.

The intention of the editors of EF is to publish research papers and technical notes relating to experimental methods and techniques, and to their application to the solution of problems in fluid mechanics. They specify that contributions to the journal should encompass a wide range of applications, including aerodynamics, hydrodynamics, basic fluid dynamics, convective heat transfer, combustion, biological and geophysical flows and turbomachinery.

In the issues published to date there have been no editorial reviews or comments, or book reviews, but there seems to be no editorial policy excluding such features. Currently the publication time for articles appears to be very fast, with about a six-month gap between date of receipt and final publication. Authors receive 50 free off-prints of their published papers, a welcome bonus, but the journal's cost of $97 per year for individuals seems rather expensive. The quality of production of articles is good, although there is nothing exceptional about the standard of illustrations.

The contributions published so far deal with both experimental techniques and detailed flow measurements, and certainly meet the requirements of the editors in respect of range of topics. In at least one paper attention is given to an uncertainty analysis of the measured data, but it cannot be overemphasized that such analysis should be given prominence in all papers published in a journal on experimental methods and measurements.

Although the need for a new journal within fluid mechanics can be questioned, there is probably a place for one specifically associated with experimental techniques and applications. On its early showing, EF appears to be a worthy newcomer in this field. ☐

Mantle enrichment processes

C. J. Hawkesworth, N. W. Rogers, P. W. C. van Calsteren & M. A. Menzies

Department of Earth Sciences, The Open University, Milton Keynes MK7 6AA, UK

A review of Sr- and Nd-isotope and selected trace element data in both within-plate basalts and mantle xenoliths suggests that at least two enrichment processes are active within the upper mantle. One is consistent with the migration of small volume silicate melts with 'basanitic' trace element distribution patterns, whereas the other is characterized by relatively high ε_{Sr}, Rb/Sr and K/Ti ratios, as observed in K-richterite-bearing periodotite xenoliths.

THE Earth's mantle consists predominantly of Fe, Mg and Al silicates and it is probably fairly homogeneous with respect to major elements. However, mantle trace elements are distributed heterogeneously and these are particularly useful in attempting to describe different domains in the upper mantle and how they may have evolved. Trace elements are only present in very low concentrations and thus they rarely form minerals of their own. Many are termed incompatible because they do not sit readily in the crystal structure of common mantle minerals and so they concentrate in any small volume fluid or melt phase that may be present. Some incompatible elements are radioactive and potentially the changing isotope abundances of their daughter products allow evaluations of the age of individual mantle domains and of the timing of certain upper mantle processes. However, any interpretation of the observed variations in radiogenic isotopes should be allied to an understanding of the processes responsible for the distribution of the parent and daughter elements in the upper mantle. The composition of the mantle may be inferred from studies of basalts, and determined directly on rare samples of mantle rocks transported to the surface either tectonically or as xenoliths (fragments) in mantle-derived magmas. Such samples provide both mineralogical and chemical evidence for the changes that can result from processes that enrich and deplete trace elements in the upper mantle. This review considers the extent to which information on mantle trace-element enrichment processes from mantle xenoliths may be reconciled with some of the trace-element and radiogenic-isotope variations in recent basalts.

Trace elements

The upper mantle is heterogeneous with respect to trace element ratios as well as abundances. Those portions that are enriched in trace elements relative to the mantle source of mid-ocean ridge basalts (MORB) or to best estimates of the primitive mantle testify to processes that scavenge and then concentrate these elements. Moreover, when trace-element enrichment results in changes in Rb/Sr, Sm/Nd and U/Pb, they will with time generate different Sr-, Nd- and Pb-isotope ratios. Yet, ironically, while the evidence for trace-element enriched areas in the upper mantle is generally accepted, there is widespread reluctance to believe that they may develop slightly unusual radiogenic isotope ratios.

The root of this reluctance arguably lies in one of the more spectacular applications of radiogenic isotopes, the models for the chemical evolution of the Earth[1-3], for these models suggest that the chemical evolution of at least the outer portions of the Earth can be reasonably described in terms of a primitive mantle reservoir that differentiates to form the crust and a residual or depleted mantle. With the passage of time, and the radioactive decay of ^{87}Rb and ^{147}Sm, the crust evolves high ^{87}Sr/^{86}Sr and low ^{143}Nd/^{144}Nd ratios and the depleted (MORB-type) mantle has the complementary low ^{87}Sr/^{86}Sr and high ^{143}Nd/^{144}Nd. Consequently, both have similar average model ages of 1,900–1,700 Myr. The problem is how to describe and interpret any compositions intermediate between the selected values for the crust and the depleted mantle. Within the confines of these models, the intermediate compositions can be described in terms of the chosen 'endmembers' of crust and depleted mantle. However, the success of the models has encouraged the two-component approach in other areas, in interpreting both the isotope ratios observed in individual magmatic provinces and the overall array of isotope data on mantle-derived rocks.

Figure 1 summarizes some of the Nd-isotope results available on fragments of the upper mantle brought to the surface as xenoliths in alkali basalts and kimberlites[4-9]. Most were determined on separated minerals that, unlike the whole rocks, appear not to have been contaminated with the host magma en route to the surface. The data range from high ^{143}Nd/^{144}Nd ratios indistinguishable from those of MORB to low values often regarded as typical of crustal rocks. Thus not all mantle-derived rocks are depleted isotopically relative to the bulk Earth, and particularly in continental areas where old segments of mantle may be preserved within the continental lithosphere, it seems that mantle rocks can have comparable radiogenic isotope ratios to those in the overlying crust. For Nd, Sr and even Pb isotopes, caution is needed before arguing that isotope ratios which indicate trace-element-enriched source regions are necessarily derived from the crust. Crustal contamination may be better

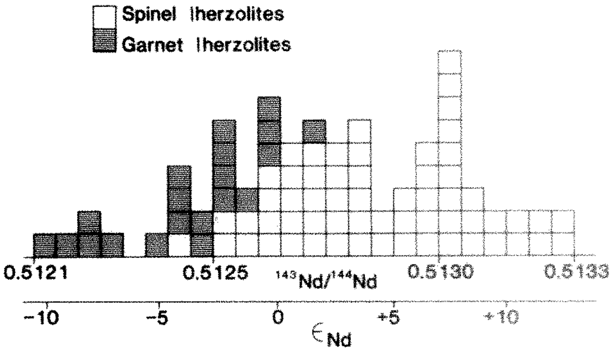

Fig. 1 Present day Nd-isotope composition of clinopyroxenes in spinel and garnet lherzolite inclusions from alkali basalts and kimberlites[4-9]. $\varepsilon_{Nd}(T)$ is the deviation from the value expected in a chondritic reservoir (CHUR) at time T, and is defined as

$$\varepsilon_{Nd}(T) = 10^4 \left[\frac{^{143}\mathrm{Nd}/^{144}\mathrm{Nd}_{\mathrm{rock}}(T)}{^{143}\mathrm{Nd}/^{144}\mathrm{Nd}_{\mathrm{CHUR}}(T)} - 1 \right]$$

where

$$^{143}\mathrm{Nd}/^{144}\mathrm{Nd}_{\mathrm{CHUR}}(T) = 0.51264 - 0.1967[(\exp \lambda_{\mathrm{Sm}} T) - 1].$$

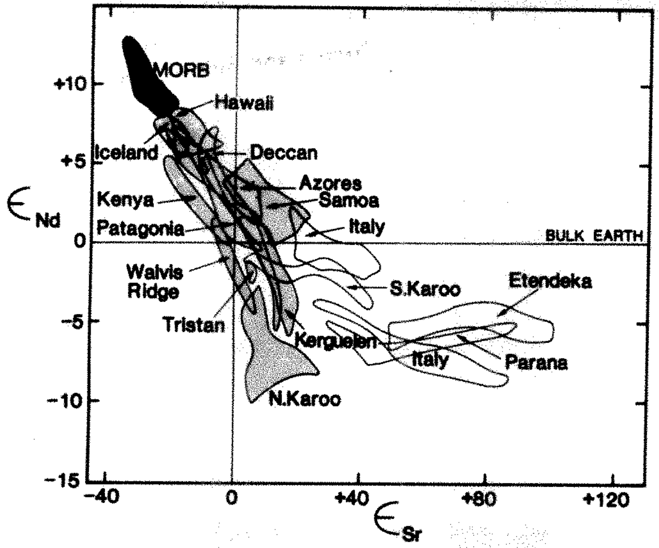

Fig. 2 Nd- and Sr-isotope compositions of selected Jurassic–Recent volcanic rocks[12–28]. The shading identifies MORB and two groups of within-plate basalts which tend to have different minor- and trace-element characteristics (see, for example, Figs 3, 4).

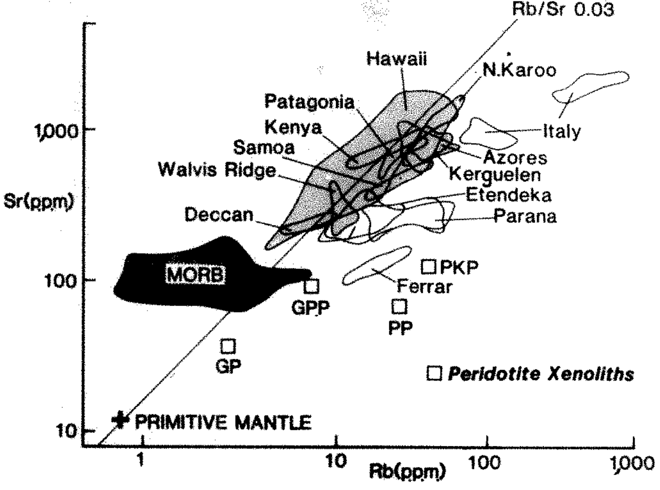

Fig. 3 Rb and Sr variations in selected MORB glasses, peridotite xenoliths and within-plate basalts[5,12–26,35,75–84]. For the peridotites and many basalt provinces average values have been plotted. Ferrar dolerites are included because of their high ε_{Sr} values in primitive rocks[42], even though ε_{Nd} data are not available. Shading as in Fig. 2. GP, garnet peridotites; GPP, garnet phlogopite peridotites; PP, phlogopite peridotites; PKP, phlogopite K-richterite peridotites[5].

demonstrated by the changes in isotope composition that will result from any contamination process, than by appealing to the discriminating powers of specific radiogenic isotope ratios.

The counter argument to such evidence for a mantle relatively enriched in radiogenic isotopes is that while xenoliths in kimberlites are interesting in their own right, they might come from anomalous segments of mantle and so might not be relevant to the study of basalts and their mantle source regions. The evidence from xenoliths need not, therefore, deflect attempts to model the isotope ratios of within-plate basalts in terms of crust and depleted mantle. Moreover, because most xenoliths from kimberlites are too impoverished in those major elements that are enriched in basalt, and are therefore incapable of producing much basaltic melt[10], it is not an argument that can be lightly dismissed.

One way of assessing the significance of mantle enrichment processes is to compare not simply the isotope ratios in basalts and xenoliths, but also variations in minor and trace elements, and hence the coherence between isotope and trace element compositions[11]. This review therefore focuses on certain aspects of the minor- and trace-element variations in mantle xenoliths and basalts which, in conjunction with the Nd- and Sr-isotope data, offer some constraints on the nature of mantle enrichment processes. The discussion is deliberately restricted to Nd and Sr isotopes because their distribution and that of their parents Sm and Rb may be more readily related to that of other commonly analysed trace elements than can, for example, the rare gases or even U and Pb.

Nd and Sr isotopes

Detailed studies have been carried out on a wide range of both oceanic and continental volcanic rocks and some of the results are summarized in Fig. 2 (refs 12–28). Data have been omitted both for clarity, where they exhibit similar trends to those already plotted, and where a reasonable case exists for contamination with continental material as mantle-derived magmas migrate up through the crust (for example, the south Lebombo basalts of the Karoo[24], the lower lavas of the Mahabaleshwar section of the Deccan Traps[20,27] and the British Tertiary[29]. Overall, the inverse correlation of ε_{Nd} and ε_{Sr} defines a broad swathe of results through a point representing the estimated composition of the undifferentiated bulk Earth[28]. Most basalts have positive ε_{Nd} and negative ε_{Sr} (low $^{87}Sr/^{86}Sr$) values and were, therefore, derived from source regions which had low Rb/Sr and Nd/Sm for much of their history; that is, they were relatively depleted in the more incompatible elements such as Rb and the light rare-earth elements (LREEs). Conversely, rocks with negative ε_{Nd} and positive ε_{Sr} contain at least a contribution from sources that had high Nd/Sm and Rb/Sr ratios, and hence by implication were relatively enriched in incompatible elements, for long periods of time. Many crustal rocks have similar ε_{Nd} and ε_{Sr} values, but then so too do some peridotite mantle xenoliths and the diopsides separated from them (refs 4, 5, 30 and Fig. 1).

The issue is the extent to which the broad trend of the Nd- and Sr-isotope data reflects mantle processes operating on the global scale, including the recycling of continental material. The models of Earth evolution rely heavily on the complementary nature of the crustal and depleted (MORB-type) mantle reservoirs, and the shape of the data array is broadly consistent with two-component mixing. Thus, there has been much speculation that this array is due primarily to mixing between continental and depleted mantle material, with the former being introduced either in subducted ocean crust[18,30] or as portions of the continental lithosphere re-assimilated back into the convecting upper mantle[31,32] or by straightforward contamination of mantle-derived magmas en route to the surface in continental areas[33]. However, recent basalts also exhibit a curved negative correlation between Sm/Nd and Rb/Sr (ref. 17). This is consistent with the available information on the distribution of those elements between coexisting mantle phases[34], and it implies that the ε_{Nd}–ε_{Sr} array might equally reflect the fractionation of Sm/Nd and Rb/Sr in a whole series of localized enrichment and depletion events in the upper mantle.

Figure 2 shows the data on intraplate basalts, subdivided on the basis of ε_{Nd} and ε_{Sr}, and the minor and trace element variations illustrated in Figs 3 and 4. One group largely plots on or to the left of the steep portion of the array, with the possible exception of those from Samoa and perhaps the Azores which are discussed below, whereas the samples in the other group are displaced to relatively high ε_{Sr} values. Moreover, while rocks in the first group occur in both oceanic and continental areas, those with relatively high ε_{Sr} seem to be restricted to the continents. This observation suggests that mantle source regions with similar trace element histories are sampled in both environments, and that the high ε_{Sr} values are due to contamination with contiental crust and/or to a different trace-element enrichment process apparently confined to the sub-continental mantle.

Trace-element studies have demonstrated that some basalts have high concentrations of incompatible elements, including

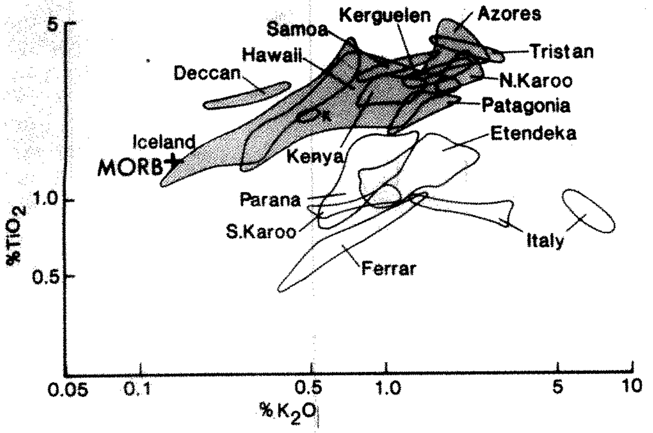

Fig. 4 TiO_2 and K_2O variations in the basic volcanic rock suites for which ε_{Nd} and ε_{Sr} data are plotted in Fig. 2. The exceptions are the Ferrar dolerites which are included because of their high ε_{Sr} values, although ε_{Nd} data have not yet been published. Shading as in Fig. 2. K, small subset of Kerguelen data. Typical MORB from ref. 40.

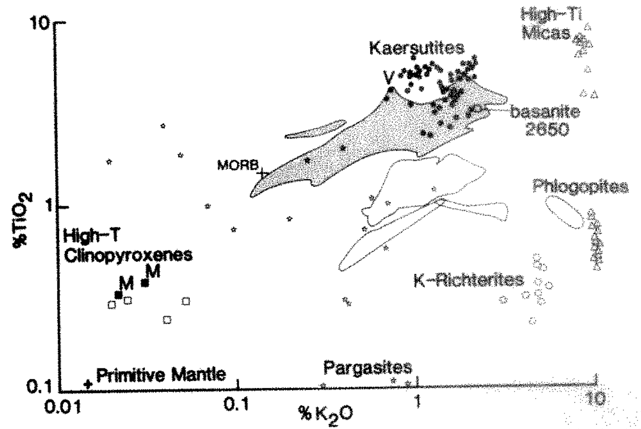

Fig. 5 TiO_2 and K_2O contents of micas, amphiboles and high-temperature clinopyroxenes[45–50,52–61,67–71] compared with trends identified in basalts in Fig. 4. The high Ti-micas, kaersutites and pargasites are from inclusions in alkali basalts, whereas the phlogopites, K-richterites and clinopyroxenes are from inclusions in kimberlite. V, vein sample; M, megacryst from kimberlite. Open squares, diopsides from high-temperature peridotites.

the LREEs, accompanied by comparatively low or unfractionated Rb/Sr ratios, while in others high incompatible element contents are accompanied by high Rb/Sr ratios[17,21,23,24,35]. These differences seem to reflect different trace-element enrichment processes in the upper mantle, and with time they will generate low ε_{Sr}, low ε_{Nd} and high ε_{Sr}, low ε_{Nd} trends respectively on the Nd–Sr isotope diagram.

The case for the existence of different trace-element enrichment processes is supported by studies on garnet- and amphibole-bearing peridotite xenoliths from kimberlite pipes in southern Africa[4,5,36], and by studies on apatite pyroxenite inclusions from south-east Australia[37]. Most cold, coarse peridotites from southern Africa are enriched in LREEs, and hence have low Sm/Nd ratios, but those which contain garnet ± phlogopite are characterized by low Rb/Sr, in contrast to those that are garnet-free and contain phlogopite ± K-richterite and have high Rb/Sr ratios (see average values on Fig. 3). With time the low Sm/Nd, low Rb/Sr rocks have evolved on or to the left of the ε_{Nd}–ε_{Sr} array, and the high Rb/Sr, low Sm/Nd samples have generated relatively high ε_{Sr}, low ε_{Nd} values comparable with those in the Italian and South Karoo basalts in Fig. 2 (refs 11, 23). Furthermore, if mantle-enrichment processes are primarily responsible for such coherent variations in Rb/Sr and Sm/Nd (and hence ε_{Sr} and ε_{Nd}), they should also result in other minor- and trace-element differences that might, for example, be more sensitive to the nature of those enerichment processes.

Rb, Sr and TiO_2, K_2O

There have been surprisingly few attempts to analyse minor- and trace-element variations in mantle-derived rocks in the context of mantle-enrichment processes, and there is only room here for some preliminary speculations. It has been demonstrated[5,11,24] that Rb/Ba ratios were remarkably similar in both garnet and garnet–phlogopite lherzolite xenoliths from Kimberley and in many Karoo basalts, even though average Ba contents ranged from 19 p.p.m. in xenoliths up to 920 p.p.m. in nothern Karoo lavas. All these rocks plotted on or to the left of the ε_{Nd}–ε_{Sr} array, and any group of rocks that had high Rb/Ba ratios also had relatively high ε_{Sr} values (for example, the Etendeka[24] in Fig. 2). However, there are fewer Rb/Ba than Rb/Sr data available in the literature, and since variations in Rb/Sr may also be related more directly to those in $^{87}Sr/^{86}Sr$, Rb and Sr results from some basalts and mantle xenoliths are outlined in Fig. 3 to investigate this line of argument further.

Where possible, the analyses used in compiling Fig. 3 are on the same rocks as those in Fig. 2, although for many provinces, average Rb and Sr values have been plotted. This is partly because in some instances only average values are available, and partly for clarity because it minimizes the scatter. The averages are based on local criteria such as magma type, stratigraphical unit and radiometric age. What is striking is that even though Rb/Sr ratios are highly susceptible to low-pressure effects such as plagioclase fractionation, there are still strong links between Rb/Sr and ε_{Sr} (refs 38, 39). The basalts with high Rb/Sr have relatively high ε_{Sr}, and those with comparatively unfractionated Rb/Sr ratios plot on or to the left of the steep portion of the ε_{Nd}–ε_{Sr} array.

Such consistency between isotope- and trace-element ratios is reassuring, but it is difficult to evaluate by studies of mantle xenoliths because of practical problems in obtaining representative, or even reliable, trace-element data from many mantle rocks. However, several studies have reported high quality microprobe analyses on mantle minerals so that if the inferred styles of trace-element enrichment could be recognized in at least minor element variations, it should be possible to evaluate them by comparison with the minor-element variations in mantle minerals.

The minor elements selected were Ti and K and the results were treated in the same way as the Rb and Sr data. Most basalts from both oceanic and continental areas plot on a broad array within which Ti/K decreases from ~7 in typical MORB[40] to ~1.4 in incompatible element-enriched basalts on oceanic islands such as Sao Miguel in the Azores and Tristan da Cunha (Fig. 4). Significantly, however, those basalts which have relatively high ε_{Sr} (Fig. 2) appear to be characterized by relatively low Ti contents, and hence low Ti/K ratios (~1–0.1). Once again high $^{87}Sr/^{86}Sr$ ratios consistently occur in rocks which have distinctive minor-and trace-element features. Crustal contamination will tend to reduce Ti/K, but significant amounts of contamination are required if that is to be the cause of the observed low Ti/K ratios. For example, to generate a basalt with 1% TiO_2 and 1% K_2O from typical MORB[40] implies 30% contamination, even in the most advantageous conditions of a TiO_2-free contaminant (whereupon the contaminant would have ~2.5% K_2O), and the amount of contamination is not reduced by invoking assimilation with fractional crystallization[41] and/or a contaminant with higher K_2O. Yet both the high Ti and low Ti trends include primitive basalts with so-called 'mantle' $\delta^{18}O$ values of 6.0±0.5‰ (refs 42, 43, and R. S. Harmon, personal communication), suggesting that it is most improbable that the difference between the two trends is due to crustal contamination.

Further evidence for attributing different Ti–K trends to mantle processes comes from the variation of Ti contents, in particular in mantle phases. The textural relations of, for example, phlogopite in mantle xenoliths are extremely complex, and while many authors have identified 'primary' and 'secondary' phlogopite mica[44–50], it is often unclear whether the latter reflect mantle metasomatic processes or interaction with the host kimberlite. In general, secondary micas have higher and more variable Ti contents and in this discussion we have assumed that they reflect kimberlite interaction, and so have not considered them further. Primary phlogopites have $\leq 1\%$ TiO_2 (ref. 46) consistent with the low TiO_2 contents of the amphibole with which they are most often associated K-richterite (see Fig. 5) and the low Ti/K whole rock ratios of the phlogopite–richterite peridotite suite[48]. The identification of Ti-rich accessory phases in association with richterite[51] indicates that Ti is also mobilized in this process, even though the overall character is one of alkali enrichment. Moreover, since these metasomatized xenoliths also exhibit relatively high Rb/Ba, Rb/Sr and ε_{Sr} values[5], they have both minor- and trace-element and Nd–Sr isotope features remarkably similar to those of the low Ti/K, high $^{87}Sr/^{86}Sr$ continental basalts (Figs 2, 4).

Spinel peridotites also exhibit isotope- and trace-element features consistent with trace-element enrichment after some previous major-element depletion episode[49,50]. However, unlike garnet peridotites, spinel peridotites occur predominantly in alkali basalt provinces, and 'metasomatism' tends to be associated with multiple intrusions of alkali-rich or 'basantic' silicate magma[52–61]. Composite xenoliths preserve a record of pyroxenite veins cross-cutting peridotite, and the common amphibole is kaersutite which can occur in veins, poikilitically within the host lherzolite or as megacrysts in alkali-rich basalts. Phlogopite is rare, and when present it is usually Ti-rich, so that both the amphibole and mica commonly associated with trace-element enrichment in the spinel lherzolite facies have the relatively high Ti/K ratios characteristic of most oceanic and continental within-plate basalts. Moreover, both the basalts on the high Ti/K trend and clinopyroxenes and kaersutites from spinel lherzolites tend to have low $^{87}Sr/^{86}Sr$ ratios, <0.7055 (ref. 50).

The amphibole pargasite also occurs as megacrysts and in spinel lherzolites, and yet it is characterized by highly variable K and Ti contents (Fig. 5) and locally it is associated with low-Ti phlogopite[62]. However, the scatter of K and Ti data indicates that pargasite has no simple relationship with the processes responsible for the coherent trends in the basalts. It has been argued, for example, that pargasite may form during wall rock alteration around magma conduits[61].

Magma migration or metasomatism?

The descriptions of trace-element enrichment processes inferred from mantle xenoliths vary significantly from spinel- to garnet-bearing suites. The former emphasize the role of associated magmatism; veins and megacrysts testify to the transfer of material in silicate melts, and chemical metasomatism of the country rocks may be largely restricted to the contacts with veins and conduits. In contrast, discussions of xenoliths from kimberlites, particularly from the Kimberley area where most work has been done on K-richterite bearing rocks[5,46], often appeal to 'pervasive metasomatism and the infiltration of H_2O-rich fluids', and comparatively few vein textures have been reported. Thus, it is very tempting to attribute the low Ti/K, high Rb/Ba, Rb/Sr and subsequently high ε_{Sr} style of enrichment recognized in both basalts and mantle xenoliths in this form of mantle metasomatism, to the infiltration of H_2O- and alkali-rich fluids. Such fluids probably reflect different processes in different areas, but there is increasing evidence from the Italian volcanics (see Figs 2–4) that, at least locally, this style of trace-element enrichment can be related to subduction[62,63]. The more common high Ti/K style of enrichment occurs in both oceanic and continental areas, and the evidence from spinel lherzolites and megacrysts indicates that it reflects the migration of small volumes of silicate melt. It concentrates a spectrum of trace elements from Rb, K, Ba, through Nb, Ta and the LREEs, to Zr and Ti, with the result that within-plate basalts may be characterized on discriminant diagrams intended to distinguish basalts erupted in different tectonic settings[64], and many of the more incompatible element-enriched basalts on the high Ti trend have trace-element-normalized patterns similar to those of basanites. LREE abundances increase, and so Sm/Nd ratios are low, but there is relatively little increase in Rb/Sr and the basalts and xenoliths consistently plot on, or to the left of, the steep part of the ε_{Nd}–ε_{Sr} array.

These features appear to be characteristic of enrichment processes in the convecting upper mantle and they are also observed in discrete nodules (or megacrysts) and high-temperature deformed peridotites from kimberlite pipes[65,66]. Clinopyroxene megacrysts and separates from high-temperature peridotites have both low $^{87}Sr/^{86}Sr = 0.7024$-0.7036 (refs 67–69) and high Ti/K ratios[70,71] comparable with those of the high Ti/K basalt trend (Fig. 4). Thus the isotope- and trace-element compositions, and the pressure–temperature (P–T) conditions of equilibration, of the high-temperature peridotite are predominantly asthenospheric in character; as are the megacrysts which appear to have crystallized from high-temperature Ti-rich magmas derived from the convecting upper mantle. Harte[66] has recently developed this argument to show that using partition coefficients for basaltic magmas the estimated trace-element composition of magma in equilibration with a clinopyroxene megacryst from kimberlite is very similar to that of basanite 2650 from Frey *et al.*[34] (see Fig. 5), which is believed to be a good example of a small-volume mantle melt.

Discussion

This preliminary review of minor- and trace-element and Nd-, Sr-isotope data on within-plate basalts and on xenoliths containing hydrous mantle phases suggests that at least two enrichment processes are active in the upper mantle. In reality there is probably a continuum of enrichment processes. Volcanic rocks with ε_{Nd}–ε_{Sr} values on, or to the left of, the mantle array have trace-element compositions consistent with the migration of small volumes of 'basanitic' melts within their upper mantle source regions. This seems to be the dominant enrichment process in both oceanic and continental areas and it can be observed directly in the composite spinel lherzolite xenoliths which are a feature of many young alkali basalt provinces. In addition, basanitic high-Ti, low $^{87}Sr/^{86}Sr$ magmas have been in equilibrium with the megacryst suite in kimberlites and responsible for the Fe–Ti enrichment in high-temperature deformed peridotites[65]. In contrast, basalts from some provinces are characterized by relatively high ε_{Sr}, Rb/Ba, Rb/Sr and K/Ti—as are metasomatized phlogopite + K-richterite-bearing peridotite xenoliths. These represent a different style of mantle enrichment which is apparently confined to continental areas. It probably results from more than one process, but there is evidence from the Italian volcanics, for example, that, at least locally, it can be related to the release of H_2O- and alkali-rich fluids above a subduction zone[62,63].

There has been some debate over the timing of mantle-enrichment events and their relation to volcanism[72]. In many areas, trace-element enrichment seems to have been closely associated with, and may locally have been responsible for, magma genesis[9,17,73]. Interestingly, however, such magmatic provinces all seem to lie on the high Ti/K trend and it has been suggested that this enrichment reflects the migration of small-volume partial melts. The low Ti/K style of enrichment seems to have no such simple relationship to magma genesis, although in the case of the K-richterite metasomatism in xenoliths from southern Africa, it takes place soon after the widespread Karoo magmatism (ref. 11 and refs therein).

Note that none of the figures used here are intended to be discriminant diagrams, particularly in assessing the effects of crustal contamination. The analyses plotted in Figs 2–4 are from suites in which at least the primitive rocks do not seem to have been affected significantly by crustal contamination. So, although it has been argued that the observed trends are due to mantle-enrichment processes, some of the effects, such as high ε_{Sr}, can also result from crustal contamination. The case for crustal contamination must be reviewed separately for each area, and with the possible exception of high $\delta^{18}O$ values, it leaves few unambiguous fingerprints.

Finally, there is the question of the extent to which these postulated trace-element-enrichment processes are responsible for the observed range in ε_{Nd} and ε_{Sr} in recent basalts, or whether the latter primarily reflect an additional component such as subducted crust[18,30] or re-assimilated continental lithosphere[32]. The coherence between the minor-and trace-element and the isotope trends implies that they are related, and the obseved range in Rb/Sr (Fig. 3) and Sm/Nd (which decreases as Rb and Sr contents increase, Fig. 3) appears to be sufficient to generate the variations in ε_{Nd} and ε_{Sr}. This suggests that an additional (continental) component may not be necessary to explain the trends in ε_{Nd}–ε_{Sr}, except perhaps in areas where inconsistencies exist between the isotope and trace-element data. Such a case may be made for the Azores and Samoa[18] rocks because they have slightly high ε_{Sr} (Fig. 2) and yet still plot on the high Ti/K trend (Fig. 4), but whether that inconsistency is sufficient to require a recycled component to explain the isotope results remains conjectural. It has also been suggested that the ε_{Nd}, ε_{Sr} values of ocean island basalts may primarily reflect the recycling of high ε_{Sr} material from the continental lithosphere[32]. However, such material seems to be characterized by low Ti/K ratios so that it could not control the volumetrically dominant high Ti/K trend in Figs 4, 5—and that would imply that the links between the isotope and minor-element trends identified here are coincidental.

Continental material appears to be recycled into the upper mantle by subduction[18,30], and it may well have influenced the actual ε_{Nd} and ε_{Sr} values estimated for the average upper mantle[74]. However, the systematic minor- and trace-element differences in basalts and mantle xenoliths which exhibit different Nd- and Sr-isotpe trends suggests that the relative fractionation of ε_{Nd} and ε_{Sr} is closely related to the postulated trace-element enrichment processes. The dominant process results in high Ti/K, low Sm/Nd and little fractionation of Rb/Sr, consistent with the migration of small-volume partial melts within the convecting upper mantle. Such melts can be derived from variously depleted and more primitive mantle reservoirs and convection will probably ensure that the enriched portions of mantle are comparatively short-lived, being continually created and destroyed.

We thank K. G. Cox, G. C. Goles, B. Harte, E. Jagoutz and W. P. Leeman for their constructive criticisms of earlier versions of the manuscript. The work was supported in part by NERC grant GR3/4330, and the manuscript was typed by Janet Dryden.

Casimir effect for massive photons

G. Barton & N. Dombey

School of Mathematical and Physical Sciences, University of Sussex, Falmer, Brighton BN1 9QH, UK

The suggestion that the force between two perfectly conducting plates in quantum electrodynamics depends critically on whether the photon mass is precisely zero or not is false. The solution to this problem involves the discovery of a new class of classical solutions for the electromagnetic field between conducting plates, when the photon has non-zero mass.

THE inverse-power-law forces that act between macroscopic bodies as a consequence of the van der Waals forces between their constituents are not unexpected. They are understood as ordinary electromagnetic forces between charge and current fluctuations at the molecular level. One might then expect a similar interaction between (idealized) perfectly conducting bodies, obtainable from the theory for ordinary conductors and dielectrics by some appropriate limiting procedure.

In contrast to such explanations of these interactions, which focus on charges and currents, the forces between perfect conductors can be understood very simply and directly from an alternative point of view which focuses on the electromagnetic field, and ascribes the forces to changes in the quantum zero-point energy of the field normal modes when the conductors are introduced. The conductors affect the normal modes through the boundary conditions which the fields must satisfy on the conducting surfaces. Accordingly the forces depend only on Planck's constant $\hbar$ (characteristic of quantum mechanics), the speed of light c (characteristic of Maxwell's electromagnetic field equations), and on purely geometrical factors (characteristic of the spatial configuration of the conductors). The archetype of all such phenomena is the Casimir effect[1], the attractive force F (per unit area) between two perfectly conducting slabs separated by a distance $2L$

$$F = -\frac{\pi^2}{240}\frac{\hbar c}{(2L)^4} = -\frac{\partial U}{\partial(2L)}$$

$$U = -\frac{\pi^2}{720}\frac{\hbar c}{(2L)^3}$$

The connection between this approach and the more conventional one has been much discussed by, for instance, Lifshitz and Pitaevskii[2] and Tabor[3]. Here we shall be concerned only with the Casimir approach.

Davies and Unwin[4] considered the problem of the Casimir effect between perfectly conducting plates separated by a gap of length $2L$, assuming that the photon has a small non-zero mass m. This implies that longitudinal modes of the electromagnetic field are present in the gap in addition to the usual transverse modes given by Maxwell's theory. Davies and Unwin conclude that either: (1) the Casimir effect in this case is 3/2 times as large as the effect for $m = 0$ (because an additional longitudinal mode is present as well as the two transverse modes for each allowed frequency), or (2) the quantum-mechanical electromagnetic energy–momentum tensor diverges near a conducting plate, leading to a discontinuous change in the surface energy of the plate as compared with $m = 0$. Case (1) corresponds to an assumption of perfect reflection of the longitudinal modes; case (2) corresponds to the assumption of perfect transmission.

These results, if true, would be surprising. Stueckelberg[5] first investigated quantum electrodynamics (QED) with a massive photon and concluded that amplitudes describing longitudinal modes tended continuously to zero as $m \to 0$, provided that the electromagnetic current were conserved. This result was extended by Goldhaber and Nieto[6] who state that "in the massive photon case the fields and currents of a system are changed only by order $(mD)^2$" where D is the appropriate linear dimension of the system and we now use units $\hbar = c = 1$. It is, therefore, difficult to see how Davies and Unwin's discontinuous results can materialize in a macroscopic system when the situation is continuous on the microscopic level.

On the other hand, if a 'graviton' or Yang-Mills 'photon' is given a small mass, then the resultant theory in the zero mass limit is not the original zero mass theory[7–9]. These matters are of current interest in particle physics because the presence of a small photon mass is not allowed in a non-Abelian grand unified gauge theory such as SU(5) containing electrodynamics but is allowed in a theory which is not unified such as SU(3) × SU(2) × U(1) (ref. 10).

Classical electrodynamics, with finite photon mass, contains a new characteristic length scale, the Compton wavelength $\lambda = m^{-1}$ of the photon. Generally, a small non-zero photon mass will lead to new physical effects over a length scale λ. In particular, the effective range of electromagnetic interactions will be exponentially damped by $e^{-r/\lambda}$ and even for small values of m this leads to important effects over astronomical length scales. Because of this, the strongest indirect limits on m come from astrophysics[11]. They all arise in the same way: by considering astronomical structures in which magnetic fields are known to have a key role in maintaining equilibrium under the assumption that m is zero. The hypothesis that $m \neq 0$ will then destroy the conditions for equilibria over length scales $r > \lambda$, and hence one obtains an upper limit on m. Considerations of the Galactic magnetic field and magneto-acoustic propagation in the Crab Nebula[12–14] lead, in this way, to upper limits on m of order 10^{-20} eV. Magnetized interstellar gas clouds and interstellar gas in the disk of the Milky Way seem to require supporting magnetic field structure and hence[12,13] produce upper limits of about 10^{-25} eV. The strongest published limit on m results from an application of this argument[15,16] to magnetically supported structures in the Small Magellanic Cloud which are claimed to exist over length scales up to about 3 kpc. This leads to an upper limit of $m \leq 10^{-27}$ eV but should be examined in more detail.

Astronomical interest in the question of photon mass has been revived by the suggestion of Georgi *et al.*[17] that photon mass permits photon oscillations which could leave observable traces in the microwave background radiation in the centimetre range. Unfortunately, a high value of $m \sim 5 \times 10^{-18}$ eV seems to be required for an observable sinusoidal distortion of the black-body spectrum of the radiation.

Another area in which photon mass may have important consequences has been discussed by Fargion[18] who points out that the characteristic mass of gravitational Bose condensation in a massive photon gas is $\sim 7.5 \times 10^8 \, (m/10^{-19}\,\text{eV})^{-1} M_\odot$. This mass scale is similar to that of quasars and the nuclei of giant galaxies. It is also a mass scale that would lead to an acceptable picture of gravitational clustering, if it were the scale above which density inhomogeneities could survive damping in the early Universe[19].

This article shows that Stueckelberg *et al.* are right as far as the Casimir effect between two perfectly conducting plates is concerned: there are no discontinuities in photon mass m as $m \to 0$. Neither is there any discontinuity in surface energy. Davies and Unwin obtain incorrect results because they postulate incorrect boundary conditions: they have no freedom to choose boundary conditions because those are determined in advance by the Proca equations describing the classical electrodynamics of a massive photon. The solutions of the Proca equations are unique just as they are in Maxwell's theory.

We, therefore, outline here the solution to the Casimir effect problem assuming a photon of mass m. The details of the calculation will be given elsewhere[20] but we think that the solution involves material of general interest especially in view of the implications for particle physics and astronomy of the existence of a massive photon. The full normal mode analysis of the Proca equations is rather delicate, even in the apparently simple case of slab geometry, and the relations between certain Proca modes and the maxwellian modes are less obvious than they might seem. A systematic treatment is given in ref. 20; the statements that follow are a somewhat simplified version which is not misleading as far as the calculation of the Casimir effect is concerned. We will show that: (1) there are two independent solutions of the Proca equations for the electromagnetic field between two perfectly conducting plates which correspond to the two independent and transverse solutions of Maxwell's theory. The eigenvalue equation which determines the allowed discrete values of the wave number p perpendicular to the plates is unchanged; (2) there is a new class of solutions with a continuous spectrum in p for the Proca equations, which does not exist for Maxwell's equations; (3) the Casimir force receives contributions from both solutions (1) and (2) for non-zero m. We calculate these and show that the $m \to 0$ limit is smooth.

We also demonstrate that the solutions (in class 2) of the Proca equations, which have not been written down before as far as we are aware, are mathematically identical to the one-dimensional square well problem of Schroedinger quantum mechanics. We do not calculate the surface energy here, but we quote the result which is smooth as $m \to 0$.

Proca equations

Potentials A, ϕ are introduced in the Proca equations[11] as in Maxwell's theory satisfying the Lorentz condition

$$\nabla \cdot \mathbf{A} + \frac{\partial \phi}{\partial t} = 0 \qquad (1)$$

and the field strengths are given by

$$\mathbf{E} = -\frac{\partial \mathbf{A}}{\partial t} - \nabla \phi, \quad \mathbf{B} = \nabla \times \mathbf{A} \qquad (2)$$

The energy density T^{00} of the electromagnetic field is given by

$$T^{00} = \{(\mathbf{E}^2 + \mathbf{B}^2) + m^2(\mathbf{A}^2 + \phi^2)\}/8\pi \qquad (3)$$

so that **A** and ϕ are now physical fields which cannot be transformed away. In the presence of sources **j**, ρ satisfying

$$\nabla \cdot \mathbf{j} + \frac{\partial \rho}{\partial t} = 0 \qquad (4)$$

we have

$$\nabla \cdot \mathbf{E} = 4\pi\rho - m^2\phi \qquad (5a)$$

$$\nabla \times \mathbf{B} = 4\pi\mathbf{j} - m^2\mathbf{A} + \frac{\partial \mathbf{E}}{\partial t} \qquad (5b)$$

Following Kroll[21], we can now look for monochromatic plane wave solutions of these equations of positive frequency ω. We must have

$$\nabla \cdot \mathbf{A} - i\omega\phi = 0 \qquad (6)$$

$$\nabla^2\mathbf{A} + \omega^2\mathbf{A} - m^2\mathbf{A} = -4\pi\mathbf{j} \qquad (7a)$$

$$\nabla^2\phi + \omega^2\phi - m^2\phi = -4\pi\rho \qquad (7b)$$

For $\omega < m$, $\mathbf{q}^2 = m^2 - \omega^2$, the solutions of equations (7) can be written as

$$(A(\mathbf{r}), \phi(\mathbf{r})) = \int \frac{(\mathbf{j}(\mathbf{r}'), \rho(\mathbf{r}'))\mathrm{e}^{-q|\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r}-\mathbf{r}'|}\, \mathrm{d}\mathbf{r}' \qquad (8)$$

in terms of sources ρ, **j**. It follows that ϕ and **A** are uniquely determined by the sources and are everywhere continuous provided **j** and ϕ are not too singular. In particular, introducing the conductivity σ as usual through $\mathbf{j} = \sigma\mathbf{E}$, the case of a perfect conductor $\sigma = \infty$ is defined simply by taking $\mathbf{E} = 0$ in the conductor. In this case[21], **A** and ϕ are still continuous across the boundary of the conductor although **E** and **B** may be discontinuous.

It is easy to extend the solutions (8) to $\omega > m$ by analytical continuation. We can now investigate the Proca solutions for the fields between two perfectly conducting plane parallel plates.

Maxwellian solutions

We begin with the treatment of the maxwellian case following ref. 22. Take one conducting plate to be at $z = 0$. Then two independent solutions for $z > 0$ satisfying $\nabla \cdot \mathbf{A} = 0$, and $A_x = A_y = 0$ on the plate are

s-mode:

$$\mathbf{A} = \mathrm{e}^{-i\omega t}\, \mathrm{e}^{i\mathbf{k}\cdot\boldsymbol{\rho}} \sin pz(\mathbf{k} \times \hat{z})/\omega \qquad (9)$$

where **k** is a wave vector parallel to the plates, $\boldsymbol{\rho} = (x, y)$, $\hat{z}$ is the unit vector in the z-direction (perpendicar to the plates) and $\omega^2 = \mathbf{k}^2 + p^2$.

p-mode:

$$\mathbf{A} = \mathrm{e}^{-i\omega t}\, \mathrm{e}^{i\mathbf{k}\cdot\boldsymbol{\rho}}\, (i\mathbf{k}p \sin pz - \hat{z}\mathbf{k}^2 \cos pz)/\omega^2 \qquad (10)$$

Now consider a conducting plate at $z = 2L$. Taking $A_x = A_y = 0$ at $z = 2L$ gives the eigenvalue equation in both cases

$$\sin 2pL = 0 \qquad (11)$$

or

$$p_n = n\pi/2L, \quad \text{integral } n \qquad (12)$$

Thus the allowed frequencies for any **k** are

$$\omega_n^2 = p_n^2 + \mathbf{k}^2 \qquad (13)$$

We turn to the Proca solutions. We must now find **A**, ϕ is continuous across the plates; that is $\phi = 0$, $\mathbf{A} = 0$ for $z < 0$, $z > 2L$ with $\phi = 0$, $\mathbf{A} = 0$ on the plates themselves.

s-mode:

The mode (9) where p is given by equations (11, 12) works provided that in place of equation (13) we have

$$\omega_n^2 = p_n^2 + \mathbf{k}^2 + m^2 \qquad (14)$$

p-mode:

Now **A** of equation (10) is non-zero on $z = 0$. We write

$$\mathbf{A} = \mathbf{A}^{\mathrm{T}} + \mathbf{A}^{\mathrm{L}} \qquad (15)$$

with $\nabla \cdot \mathbf{A}^{\mathrm{T}} = 0$, $\nabla \times \mathbf{A}^{\mathrm{L}} = 0$ and define $\mathbf{A}^{\mathrm{T}}$ by the right-hand side of equation (10). We then need to look for $\mathbf{A}^{\mathrm{L}}$, ϕ, $\nabla \cdot \mathbf{A}^{\mathrm{L}} = i\omega\phi$ such that **A** and ϕ are zero at $z = 0$ and $z = 2L$.

Taking

$$\phi = (i\mathbf{k}^2(\omega^2 - m^2)/\omega^3 p)\, \mathrm{e}^{i\mathbf{k}\cdot\boldsymbol{\rho}}\, \mathrm{e}^{-i\omega t} \sin pz \qquad (16)$$

it is not difficult to show that the cosine term in $\mathbf{A}^{\mathrm{L}}$ cancels with that in $\mathbf{A}^{\mathrm{T}}$ so that **A** is proportional to sin pz. Hence the eigen-

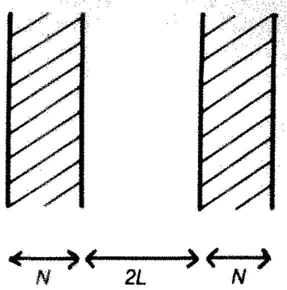

Fig. 1 Reference configuration for the continuum-mode configuration. Shaded area represents conducting plates, each of width N.

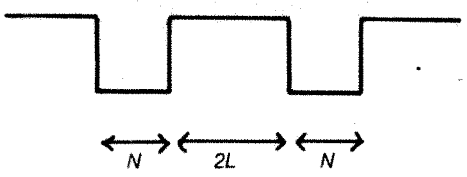

Fig. 2 Equivalent potential well in Schroedinger theory corresponding to the configuration shown in Fig. 1.

value equation for this mode is also $\sin(2pL) = 0$ provided that the dispersion relation (14) holds.

Thus the Proca solutions can be constructed out of the corresponding maxwellian solutions. It is easy to show that there are no other solutions with ϕ, $\mathbf{A}$ vanishing within the conducting plates.

Continuum solutions

We now look for solutions ϕ, $\mathbf{A}^c$ of the Proca equations of frequency ω which are non-zero within the conducting plates satisfying

$$i\omega\phi = \nabla \cdot \mathbf{A}^c \tag{17}$$

For convenience we shift the plates to be at $z = \pm L$ so that we can classify solutions as even and odd. We thus only need to consider the two regions $0 \leq z \leq L$ and $z \geq L$ corresponding to the gap and the conductor. Within a perfect conductor $\mathbf{E} = 0$. Hence

$$-\nabla\phi + i\omega\mathbf{A}^c = 0 \tag{18}$$

Combining equations (17) and (18) gives

$$\nabla^2\phi + \omega^2\phi = 0 \tag{19a}$$

and hence

$$\nabla^2\mathbf{A}^c + \omega^2\mathbf{A}^c = 0 \tag{19b}$$

In the gap, however, we have from equation (7)

$$\nabla^2\phi + (\omega^2 - m^2)\phi = 0 \tag{20a}$$

$$\nabla^2\mathbf{A}^c - (\omega^2 - m^2)\mathbf{A}^c = 0 \tag{20b}$$

From equations (19) and (20) it appears that although the (group) velocity of the photon in the gap is $v = (\omega^2 - m^2)^{1/2}/\omega < 1$ (that is, $v < c$), $v = 1$ (that is, $v = c$) in the conductor. This peculiar result was first noticed by Bass and Schroedinger[23].

The solutions of equations (19) and (20) are straightforward. First restrict motion to the z-direction perpendicular to the plates and consider the even solution

$$A_z^c = \cos pz \tag{21a}$$

$$\phi = (ip/\omega)\sin pz \tag{21b}$$

for $0 < z < L$, $p^2 = \omega^2 - m^2$, corresponding to a field strength $E_z = (im^2/\omega)\cos pz$ in the gap. In the conductor $z > L$ we have

$$A_z^c = A_0 \cos(qz + \delta_e) \tag{22a}$$

$$\phi = iA_0 \sin(qz + \delta_e) \tag{22b}$$

with $q^2 = \omega^2$ and $E_z = 0$. From continuity of $\mathbf{A}^c$ and ϕ at $z = L$, the even phase shift δ_e is determined by

$$\tan(qL + \delta_e) = (p/q)\tan pL \tag{23}$$

Similarly the odd solution for frequency ω determines the odd phase shift δ_0 by

$$\tan(qL + \delta_0) = (q/p)\tan pL \tag{24}$$

Clearly, equations (19b) and (20b) for A_z^c are just the Schroedinger equation for the scattering of a non-relativistic particle of energy E and mass M off a square barrier potential $V(z) = V_0$, $|z| < L$; $V(z) = 0$, $|z| > L$. The solutions (21a, b) and (22a, b) are the even and odd solutions to the square well problem with $p^2 = 2M(E - V_0)$, $q^2 = 2ME$ and the phase shifts δ_e and δ_0 are determined by equations and (23) and (24). The boundary conditions of continuity of A_z^c and ϕ in our case are identical to the Schroedinger conditions of continuity of the wave function and its derivative.

We conclude that an even and an odd continuum-mode solution of the Proca equations exists for any $p > 0$ with $\omega^2 = p^2 + m^2$ which has no counterpart in Maxwell theory. It is not difficult to show that the introduction of any momentum $\mathbf{k}$ parallel to the plates does not change the equations (23) and (24) which determine the phase shifts, except that now

$$\omega_p^2 = \mathbf{k}^2 + p^2 + m^2 = \mathbf{k}^2 + q^2 \tag{25}$$

Casimir effect

We now consider the quantum-mechanical part of the calculation. To calculate the Casimir force we must obtain the dependence of the total zero point energy of the system on the plate separation $2L$. This necessitates a sum over the frequencies of the classical solutions we have found. Again the problem can be separated into the contribution (A) from the maxwellian modes and the contribution (B) from the continuum modes.

The calculation of the contribution from the maxwellian modes is straightforward and has already been performed using dimensional regularization[24,25]. We prefer to use the standard treatment of the effect given in the refs 1, 26. The only change necessary going from $m = 0$ to $m \neq 0$ is that the appropriate dispersion relation for the allowed frequencies ω_n is given by equation (14) rather than (13). This gives a contribution to the L-dependent finite part of the zero point energy $\sum_{n,\mathbf{k}} \frac{1}{2} h\omega_n$ of the maxwellian modes of

$$U(L) = -\frac{\pi^2}{3(2L)^3}\int_\mu^\infty \frac{\mathrm{d}\rho(\rho^2 - \mu^2)^{3/2}}{\mathrm{e}^{2\pi\rho} - 1} \tag{26}$$

where $\mu = 2Lm/\pi$. For $m = 0$, $\mu = 0$ and the normal expression for the Casimir energy in massless QED is obtained. Approximating equation (26) for small μ gives

$$U(L) = \frac{\pi^2}{(2L)^3}\left[-\frac{1}{720} + \frac{1}{48}\mu^2 - \frac{1}{12}\mu^3 - \frac{1}{16}\mu^4 \ln\mu + 0(\mu^4)\right] \tag{27}$$

The first term gives the normal Casimir attractive force. Note that the lowest finite mass correction tends to reduce the effect.

To calculate the contribution from the continuum modes, it is necessary to compute the change in zero point energy for the continuum modes as a result of the gap of length $2L$ from some reference configuration. It is also necessary to pose the problem in such a way as to ensure that the computation gives a finite answer. All total zero point energies are infinite and, therefore, care is needed. In our problem, the reference configuration for the continuum-mode contribution is best taken to be the situation with the two plates touching (that is, $L = 0$). As the longitudinal modes penetrate the conductors we must also consider the two conducting plates to be of finite width N. Thus, we consider the modes of the configuration shown in Fig. 1 when compared with the corresponding modes in a solid slab of conductor of total width $2N$.

The Schroedinger potential well corresponding to Fig. 1 is the double square well of Fig. 2. As the wells are now attractive there is at least one bound state of the system even for arbitrarily small m. The solutions for the bound states are obtained in the usual way for $L=0$ and for $L\neq 0$. The even and odd phase shifts are also computed as in Schroedinger theory. The contributions of any bound states and the phase shifts to the zero point energy can now be calculated using methods developed in the plasmon problem[27]. The general expression for the difference between the zero-point energies of the slab system and of the vacuum is

$$V(L, N)=\sum_b\left(-\frac{1}{12\pi}\right)[(m^2-b^2)^{3/2}-m^3)] + \frac{1}{4\pi^2}\int_0^\infty \mathrm{d}pp(m^2+p^2)^{1/2}(\delta_e+\delta_0) \qquad (28)$$

where $\sum_b$ represents a sum over bound modes having $\omega^2 = \mathbf{k}^2-b^2+m^2$, and δ_e, δ_0 are the even and odd phase shifts calculated for the double square well (Fig. 2). For the difference $U=V(L, N)-V(0, N)$ one finds eventually

$$U=\frac{1}{(2L)^3}f(mL, mN) \qquad (29)$$

where in the most favourable configuration, $L \ll N$, one finds eventually (for the realistic case mL, $mN \ll 1$)

$$f\sim\frac{1}{2\pi^2}(mL)^4\ln\left[\frac{N}{4L}\right] \qquad (30)$$

This contribution to the Casimir force is, therefore, negligible compared with the leading finite-mass correction to the contribution from the transverse modes.

Conclusions

The calculations above follow from the uniqueness of the solutions to the Proca equation. The results demonstrate that the Casimir effect is not sensitive to a small photon mass. We have not discussed surface energies here but Aoyama[28] has worked out the surface energy which results for parallel plate geometry in the case of a scalar field of mass m to be

$$S=\frac{m^3}{18\pi^2}\left(\frac{3\pi}{8}-1\right) \qquad (31)$$

and the same result is true in our case with this surface energy arising from the continuum modes. There is a corresponding term $m^3/24\pi$ from the maxwellian modes[20]. So again this effect is smooth as $m\to 0$, as[29] there is no surface energy in the corresponding problem in QED.

We thank John Barrow, Fawzi Boudjema, David Broadhurst and John Plaskett for assistance.

Anthelic arcs from airborne ice crystals

Robert G. Greenler[*‡] & E. Tränkle[†]

A new set of anthelic arcs resulting from hexagonal, pencil-shaped ice crystals that fall with their axes oriented horizontally is revealed by computer simulation. The arcs result from light rays from the Sun that experience two, and sometimes four, internal reflections in the ice crystal.

MANY optical effects result from the interaction of sunlight with airborne ice crystals that have the geometrical form of right, hexagonal prisms[1–5]. Most of the well-known halo phenomena occur within ~50° of the Sun but others do occur in different parts of the sky. An area of the sky where several rare effects are found is the region of the anthelic point. (This is the point on the opposite side of the sky from the Sun, at the same elevation above the horizon as the Sun.) Effects that have been reported in the region of the anthelic point include:

(1) Anthelic arcs—oblique arcs crossing the anthelic point. Photographs[1,6,7] and observations of anthelic arcs have been reported[8–14].

(2) Anthelion—a spot of light at the anthelic point. We know of no photographs that show the anthelion independent of other anthelic phenomena although observations have been reported and mechanisms suggested[1,6,15].

(3) Anthelic pillar—a column of light extending from slightly above the anthelic point down to the horizon. We know of only one published photograph[1,6] but observations have been reported[11,12].

(4) Parhelic circle—a circle of light parallel to the horizon passing through the Sun and anthelic point. This effect is understood to result from reflection from the vertical faces of oriented ice crystals[1–4].

Computer simulation method

All of the anthelic effects must involve at least one reflection to deflect light to the observer. The parhelic circle involves some rays that are externally reflected from the ice crystals; all other effects appear to involve one or more internal reflections.

R.G.G. *et al.* have developed a simulation method for investigating the origins of ice-crystal optical effects[1,16–18]. For a given

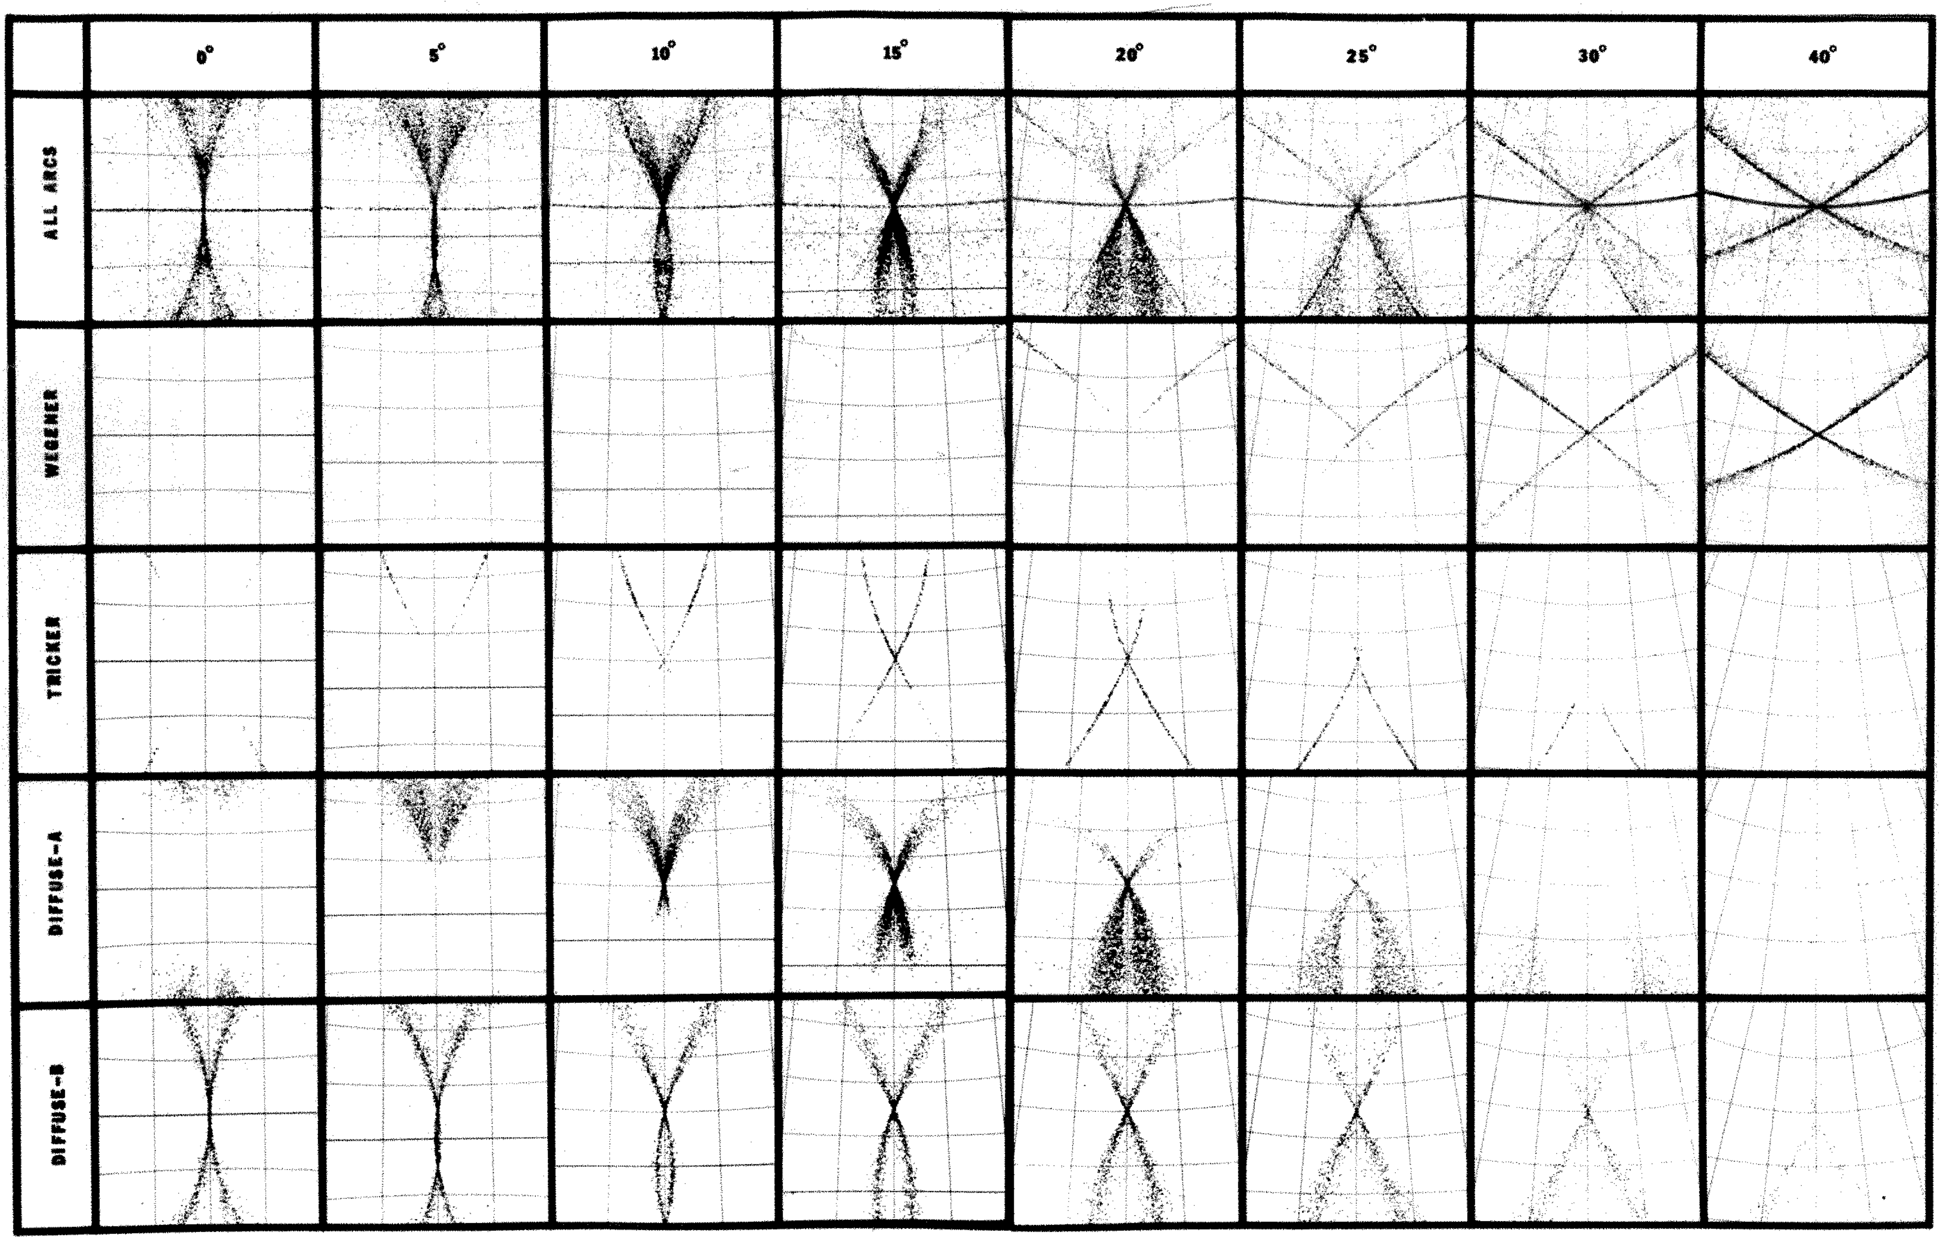

Fig. 1 Intensity patterns that simulate anthelic arcs for various Sun elevations. The grid on each figure consists of lines of constant altitude and of constant elevation, at 10° intervals. The horizon is represented by the darker horizontal line that shows no curvature.

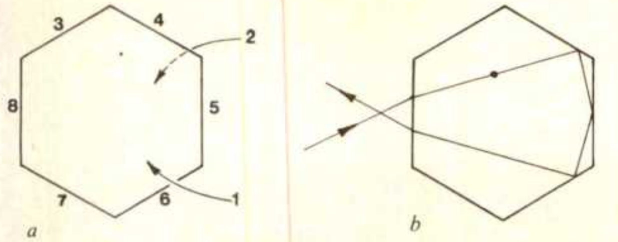

Fig. 2 *a*, Arbitrary numbering of the faces of a right hexagonal prism, representing an ice crystal. *b*, A ray path through the crystal that can be classified (by reference to *a*) as 814568.

orientation of an ice crystal, they calculate the direction of a light ray from the Sun after it has passed through specified entrance and exit faces of the crystal. This direction is translated into a position in the sky where such a crystal would be located to send the ray to the observer's eye and a spot is plotted to represent that position. For refraction phenomena, which require no internal reflections, their method handles intensity effects fairly well. The loss of intensity due to reflection at each face can be calculated. Another factor accounts for the cross-section of the incident light beam that is transmitted by both the entrance and the exit faces. Analytical expressions for both of these factors can be combined into an overall intensity factor which is used to fix the probability of whether a particular spot will be plotted—a high intensity factor yielding a high probability that the spot will be plotted. The collection of many such spots from a variety of crystal orientations gives a representation of the optical effect predicted from the collection of crystals with the given distribution of orientations and with the specified ray path through the crystal. With this method, however, it is difficult to develop the analytical intensity expression for the restriction in beam cross-section resulting from one or more internal reflections. Mallmann and Greenler used this (Monte Carlo) method to simulate anthelic phenomena[6] ignoring the geometrical intensity factor for the internal reflections.

Pattloch and E.T. have extended the Monte Carlo simulation technique so that these intensity effects can be used for any number of internal reflections[19]. They treat the light as a photon that strikes the oriented crystal at a random location. At each encounter with a crystal face, the photon is either transmitted or reflected (with a probability calculated from the Fresnel reflection coefficients). Its path through the crystal is calculated using geometrical optics and followed until it escapes the crystal and can be represented as a spot on a sky diagram. This Monte Carlo approach is used to obtain the intensities and has significant advantages over the previous method:

(1) All the reflection and refraction effects that can result from light interacting with a particular crystal shape are obtained in the simulation. Previously, only those preconceived combinations of entrance, exit, and internal reflection faces would have been investigated.

(2) The relative intensities of all the different arcs and spots are correctly represented for the shape of crystal specified.

(3) Any number of internal reflections are routinely handled. For the results shown here the calculation includes internal reflections up to 17, any more being negligible.

Additional details of the method are given in ref. 19.

Results

Figure 1 shows the simulations of anthelic effects for Sun elevations between 0° and 40°. The top row of simulations show everything predicted to occur for columnar (pencil) crystals with their main axes confined to a horizontal plane but with random orientation of the axes in that plane, and random rotational orientation of the crystals about their axes. The ratio of crystal length-to-width is 2.0. The Sun's angular diameter of 0.5° is taken into account by allowing rays to impinge on the crystal from different directions corresponding to different positions on the Sun's disk.

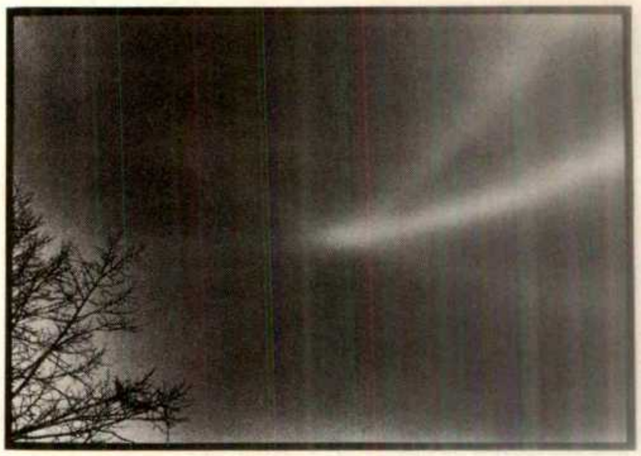

Fig. 3 Photo of the Wegener anthelic arcs and the parhelic circle for a Sun elevation of 50° taken by A. J. Mallmann in Milwaukee, Wisconsin.

If we look at the result for a Sun elevation of 20° we can see the familiar Wegener[6] arcs, the Tricker arc[6], and the parhelic circle but there are more structures that are not familiar. To investigate the source of the additional structures, we modified the computer program so that we can identify the path of a ray that is responsible for a given dot. Figure 2*a* shows an arbitrary assignment of numbers to the hexagonal crystal. The side faces are numbered 3 to 8, with the end faces identified as 1 and 2. The path of a ray through the crystal can be classified by a series of numbers beginning with the entrance face. For example, the path of the ray shown in Fig. 2*b* can be classified as 814568.

The intensity plots in the second to fifth row of Fig. 1 show effects from rays taking particular paths through the crystal. These are subsets of the intensity plots of the first row, which includes all of the effects. In each case, we have plotted all of the contributions from rays whose paths are physically equivalent to the one mentioned. For example, the rays producing the Wegener arcs are called the 814 rays but they would include rays such as 315, 416, 725, and all others that enter a side face, reflect off an end face, and exit from another side face located such that there is one face between the entrance and exit faces. For convenience, we refer to such faces as alternate side faces to distinguish them from adjacent side faces or opposite faces.

The second row represents the effect produced by rays taking the path, 814, through the crystal; these are the Wegener arcs.

We have designated as the Tricker arc, the anthelic arc that is produced by rays that enter the end face of a crystal, make two reflections from adjacent or alternate side faces, are reflected back by the opposite end face, and exit from the same end face by which they enter; for example, 18421. See ref. 1 for the argument that for Tricker's mechanism[20] "... any combination of an even number of side-face reflections plus one end-face reflection, in any order, will produce the same set of arcs". We find that rays of the type, 81463, also lie on the same locus and can contribute intensity to the Tricker arc for higher Sun elevations than those paths requiring exit and entrance through the same end face. The third row of Fig. 1 shows the Tricker arc including most of the possible contributions. The shape of the arc is the same as previously predicted[6] but the intensity distribution is altered.

As we identified the types of rays that contributed to intensity in the anthelic region, it was surprising to find that the class of rays that contribute the most intensity for Sun altitudes in the 5°–25° range had not been investigated before. The ray path is shown in Fig. 2*b*. Although it involves four internal reflections, such rays contribute significant intensity in the anthelic region of the plots of Fig. 1. For a Sun elevation of 20°, for example, with a crystal length-to-width ratio of 2.0, the intensity is greater than that from Wegener-arc rays by a factor of 13 and greater

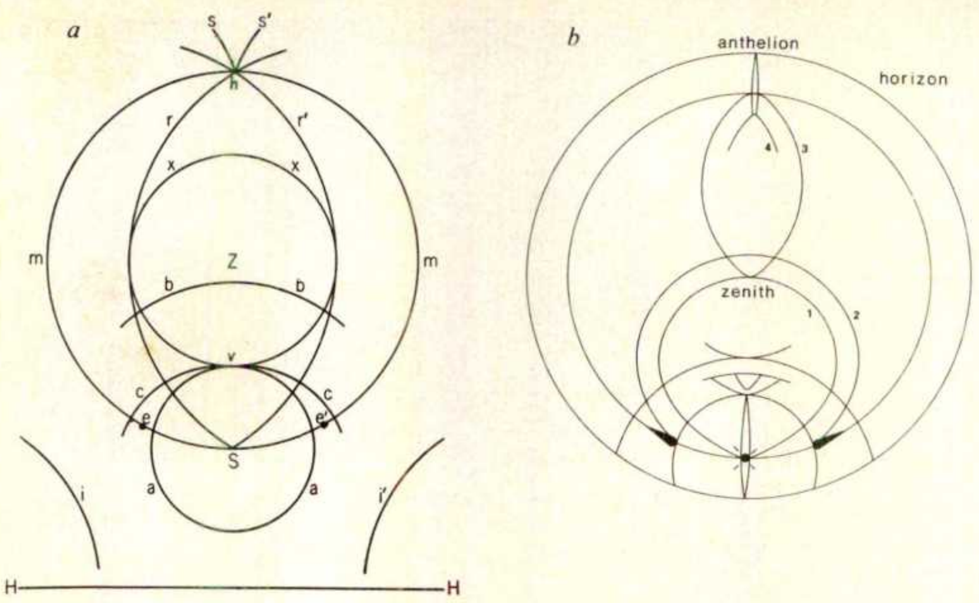

Fig. 4 *a*, Drawing of a complex display in North Dakota by F. J. Bavendick (ref. 22). *b*, Drawing of a complex display in Antarctica by J. R. Blake (ref. 11).

than that from the Tricker arc rays by a factor of 7. It is significant, however, that unlike these latter two arcs, which are quite sharp, the pattern produced by the rays of Fig. 2*b* is much more diffuse. The results are shown in the third row of Fig. 1 labelled diffuse-A.

Another class of rays (8146) also contribute a significant amount of intensity in the anthelic region. The patterns that they produce are shown in the bottom row of Fig. 1, labelled diffuse-B.

These four patterns, together with the parhelic circle, seem to account for all of the intensity patterns that can be seen in the top row. The four sets (and the parhelic circle) account for more than three-quarters of the total number of points for a Sun elevation of 20°. Some ray paths, of course, produce no arcs but add to the general background.

Discussion

The top row of simulations in Fig. 1 shows our predictions of the anthelic optical effects that result from sunlight interacting with pencil crystals with horizontal axes. It seems reasonable to classify separately only those effects that can be separated visually and identified by observation. The Wegener arcs fulfill this requirement. At Sun elevations above 30° they are the only anthelic arcs present and they can be separated from the general display for lower Sun elevations. Figure 3 shows the Wegener anthelic arcs and the parhelic circle for a Sun altitude of 50°. A few other published photos[1,6,7] confirm their reality.

The Tricker arc is seen most distinctly in our simulations for Sun elevations in the range 20°–30°. The photographic evidence for the Tricker arc is not very convincing. The complex display drawn by Bavendick[21] (Fig. 4*a*) shows two sets of anthelic arcs that are well represented by the Wegener and Tricker arcs in the simulation for 30°. (Other problems of interpretation are discussed in ref. 1). The simulations seem to show that for some Sun elevations the Tricker arc may be separated visually from the rest of the anthelic potpourri and thus should be separately classified.

For Sun elevations between 0° and 20°, the anthelic display appears to be dominated by the arcs that we have identified as diffuse arcs-A and B. Because these arcs overlap at all Sun elevations, it seems inappropriate to name them separately. Hence, we refer to the combination as the diffuse anthelic arcs.

The inensity comparison of the diffuse arc with the Tricker arc will depend on the aspect ratio of the crystal. Longer pencil crystals should show diffuse arcs that are relatively more intense than the Tricker arcs. Shorter crystals diminish the relative intensities of the diffuse arcs but as the aspect ratio approaches 1, the crystals will no longer orient with horizontal axes.

Mallmann and Greenler's simulation[6] of anthelic effects considered rays (8146) that we show here to produce the diffuse arc-B component. Their results did not show the diffuse arc but showed a concentration at the anthelic point for Sun elevations above 20° and an anthelic pillar for lower Sun elevations. Apparently, the appropriate intensity factors eliminate rays from well-defined areas of the sky and leave the diffuse arcs rather than the general background seen by Mallmann and Greenler.

Evidence for diffuse arcs

Blake's[11] drawing of the complex sky display he observed in Antarctica in 1958 is reproduced in Fig. 4*b*. Most features have been reproduced quite satisfactorially by computer simulation for a Sun elevation of 11°. The results are shown in ref. 1. The poorest agreement came in trying to match the Y-shaped structure (labelled 4 in Blake's drawing) with a Tricker arc. The diffuse arc simulation (Fig. 1, Sun elevation of 10°) seems to be a much better match for the structure. (Figure 4*b* should be inverted for comparison with the simulation of Fig. 1.)

Figure 5 shows a cusp-like arc extending below the anthelic point for a Sun elevation of 21°. The angle between the arms is consistent with that for Tricker's arc. Compared with the simulation for 20° in Fig. 1, the diffuse arcs appear to give a better representation of the width of the arms. Nothing can be seen above the parhelic circle. The simulation does show that the upper part of the diffuse arcs are less intense.

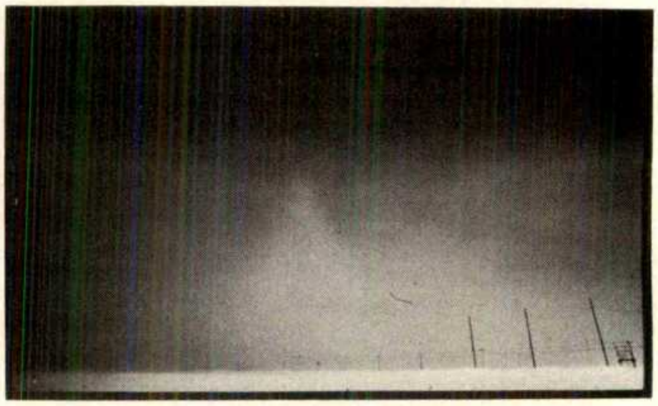

Fig. 5 Photograph of anthelic arcs for a Sun elevation of 21°, taken by R.G.G. at Point Barrow, Alaska.

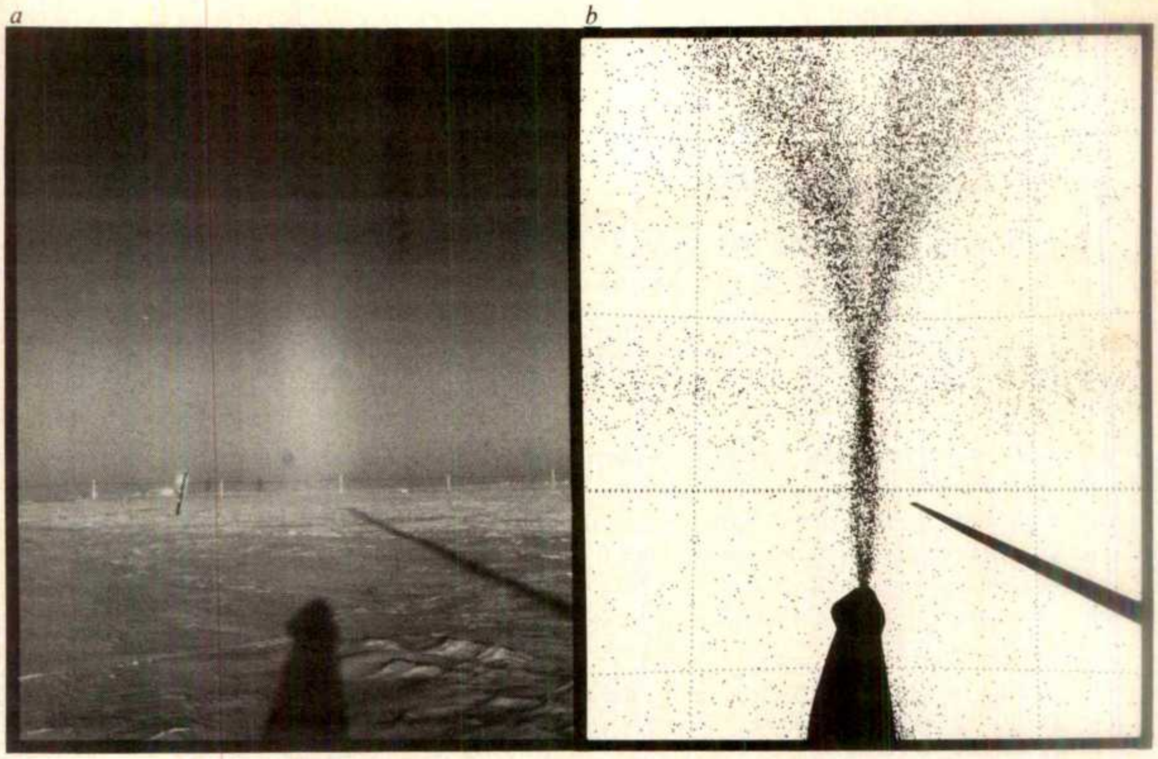

Fig. 6 Photograph (*a*) of an anthelic pillar with a Sun elevation of 6°, taken by R.G.G. at Point Barrow, Alaska. The simulation (*b*) has the same scale as the photo.

Pattloch and E.T. have simulated the effects of Hogan's South Pole photograph[19], in which the structure below the anthelic point is partially obscured by a ghost image of the Sun caused by reflections within the camera lens. The arcs extending above the anthelic point, however, seem to be matched by the combination of diffuse arcs and the Tricker arc.

Figure 6 shows a photo of the anthelic pillar together with an attempt to match it to our simulation for which the pencil crystals have a length-to-width ratio of 1.33, and the crystal axis is permitted to vary by 2° from the horizontal plane. The Sun elevation was 6° during the photo. The most obvious discrepency between photo and simulation is the absence of the upper portion of the predicted display in the photograph. The photo was taken on 28 March 1978 at Point Barrow, Alaska in the evening. Notes taken during the day indicate that various optical effects appeared and disappeared, but that the lower part of the infralateral arcs was quite persistent. Notes made immediately after the sighting and photographing of the anthelic pillar say: "The pillar appeared to be in the same layer that was giving rise to the ILA [infralateral arcs] all day; at least, the angular height of the effect corresponded to the height of the layer." An earlier note says: "The ILA seems to be formed in a cloud layer about 5° high, where it is brighter than the 22° halo." The infralateral arcs are produced by the same distribution of pencil-shaped ice crystals that are being considered for these anthelic effects. We would obviously like to have more (and better) photos of these anthelic effects for comparison with our model predictions.

In this simulation, we do not find any specific contribution that produces an anthelion. There are two possibilities. First, the brightness at the anthelic point may just be the superimposed contribution from the various arcs that intersect there. In cases where the arcs are faint, their intersection at the anthelic point may be the only spot bright enough to be seen. Second, the anthelion may exist independently of these other effects but is not caused by the pencil crystals with the orientations we assume here.

Conclusions

We have used an improved Monte Carlo simulation method to investigate optical effects near the anthelic point that result from sunlight interacting with pencil-shaped ice crystals oriented with their long axes horizontal or nearly horizontal. In addition to the previously described Wegener and Tricker arcs, we find a new set of arcs, the diffuse arcs, that are predicted to dominate the anthelic effects for low Sun elevations.

The structure, rearrangement and expression of D_β gene segments of the murine T-cell antigen receptor

It has been postulated that the variable region of the β-polypeptide of the murine T-cell antigen receptor is encoded by three distinct germ-line gene segments—variable (V_β), *diversity* (D_β) *and joining* (J_β)*—that are rearranged to generate a* V_β *gene. Germ-line* V_β *and* J_β *gene segments have been isolated previously. Here we report the isolation and characterization of two germ-line* D_β *gene segments that have recognition signals for DNA rearrangement strikingly similar to those found in the three immunoglobulin gene families and in* V_β *and* J_β *gene segments. The* D_β *and* J_β *segments can join in the absence of* V_β *gene segment rearrangement and these rearranged sequences are transcribed in some T cells.*

IMMUNOGLOBULINS and T-cell antigen receptor molecules exhibit extensive diversity but the genetic basis and the mechanisms responsible for generating this diversity are well understood only for the immunoglobulin genes[1-3]. Immunoglobulins are heterodimers made up of disulphide-bridged light and heavy chains each of which is divided into variable regions that recognize antigen, and constant regions that control effector functions. Genes that encode the variable region of light chains are created by a DNA rearrangement that joins two distinct gene segments—variable (V_L) and joining (J_L)[4-6]. The variable region genes of heavy chains are created by the joining of three distinct gene segments—variable (V_H), diversity (D_H), and joining (J_H)[7,8]. One mechanism for the generation of immunoglobulin diversity is joining of different V_H, D_H, and J_H, or V_L and J_L gene segments[9,10]. Also gene segments may be joined together at different sites, leading to a junctional variability[10-12] and in the heavy chain gene family, extra nucleotides, not found in V_H, D_H, or J_H gene segments, may be added between these gene segments as a result of the joining process (N-region diversity)[11,13]. The 3′ side of the V gene segments, the 5′ side of the J gene segments, and both sides of the D gene segments are flanked by recognition signals for DNA rearrangements. These signals comprise three components—a highly conserved palindromic heptamer, a nonconserved spacer sequence of 12 or 23 nucleotides, and a relatively conserved A/T-rich nonamer[6-8,14]. It is believed that these recognition sequences play a critical role in DNA rearrangements because they are present in all three of the immunoglobulin gene families and, therefore, have been conserved throughout vertebrate evolution.

The T-cell antigen receptor is a heterodimer composed of two disulphide-bonded polypeptides, α and β, that have a similar molecular weight[15-17]. The genes that encode the β-chain of the T-cell antigen receptor have recently been identified and they share many features with those encoding immunoglobulins. The nucleotide sequence of cDNA clones encoding the β-chain of the T-cell receptor from both mouse and man contains regions similar to V and J gene segments and C genes[18-20]. Distinct germ-line V_β and J_β gene segments and C_β genes have been isolated from genomic libraries[21-23]. Two highly similar and closely-linked C_β genes denoted $C_{\beta1}$ and $C_{\beta2}$ have been isolated on a single cosmid clone of germ-line DNA and each C_β gene has a cluster of J_β gene segments associated with it[23]. The V_β and J_β gene segments have recognition signals for DNA rearrangements that are very similar to those of their immunoglobulin counterparts[21-23].

Both murine and human β cDNA clones encoding a complete variable region contain eight or more nucleotides than their corresponding germ-line V_β and J_β gene segments suggesting that a portion of the β variable region is encoded by a third gene segment analogous to the D_H gene segment of immunoglobulins[21,22]. Indeed, in this paper we present the structure of two germline D_β gene segments. One of these D_β gene segments lies to the 5′ side of the $J_{\beta1}$ gene cluster and the second lies to the 5′ side of the $J_{\beta2}$ gene cluster, between $C_{\beta1}$ and $J_{\beta2}$. Recognition signals for DNA rearrangements on either side of these D gene segments are described, as are rearrangements and transcripts involving the D_β gene segments.

D_β gene segment of each J_β gene cluster

The partial nucleotide sequences of four murine β-chain cDNA clones have been published[19]. Two of them appeared to lack a V_β gene segment but contain joined D_β–J_β sequences. This conclusion was based on several features. First, the published sequences 5′ to the J_β gene segments resemble neither V_β gene segments nor the sequences found 5′ to the germ-line J_β gene segments. Second, in both of these clones the sequences 5′ to the joined J_β gene segment have a recognition signal for DNA joining that includes the heptamer, a 12-nucleotide spacer sequence, and the A/T-rich nonamer sequence, as well as a short sequence that could be a D_β coding segment located between the joining signal and the J_β gene segment. Two 40-base oligonucleotides complementary to a portion of these putative D_β gene segments and their 5′ flanking sequence were synthesized using the technique of Horvath *et al.*[24]. The oligonucleotide T5 is complementary to a region starting at nucleotide position 56 and ending at position 95 of the published sequence of the cDNA clone 86T5 (ref. 19). T6 is complementary to the cDNA clone TM86 at positions 15–54 (ref. 19). We have hybridized these oligonucleotides to Southern blots of a genomic cosmid clone known to contain the $J_{\beta1}$ and $J_{\beta2}$ gene clusters. T6 hybridizes most strongly to a restriction fragment located to the 5′ side of the $J_{\beta2}$ gene cluster, while T5 hybridizes more strongly to the region 5′ to the $J_{\beta1}$ gene cluster (G.S., unpublished observations). We have determined the nucleotide sequence in the vicinity of the hybridizing DNA fragments and have linked them by restriction mapping and DNA sequencing to their respective J_β gene clusters (Fig. 1 and unpublished results).

Each of these hybridizing regions appears to contain a D_β gene segment by the following criteria (Fig. 1). (1) There is a 5′ recognition sequence for DNA joining with a 12-base pair spacer sequence. (2) There is a 3′ recognition sequence for DNA joining with a 23-base pair spacer. Both of these sequences are similar to their immunoglobulin counterparts (Fig. 2). (3) One of these sequences, or a highly similar D_β gene segment, appears

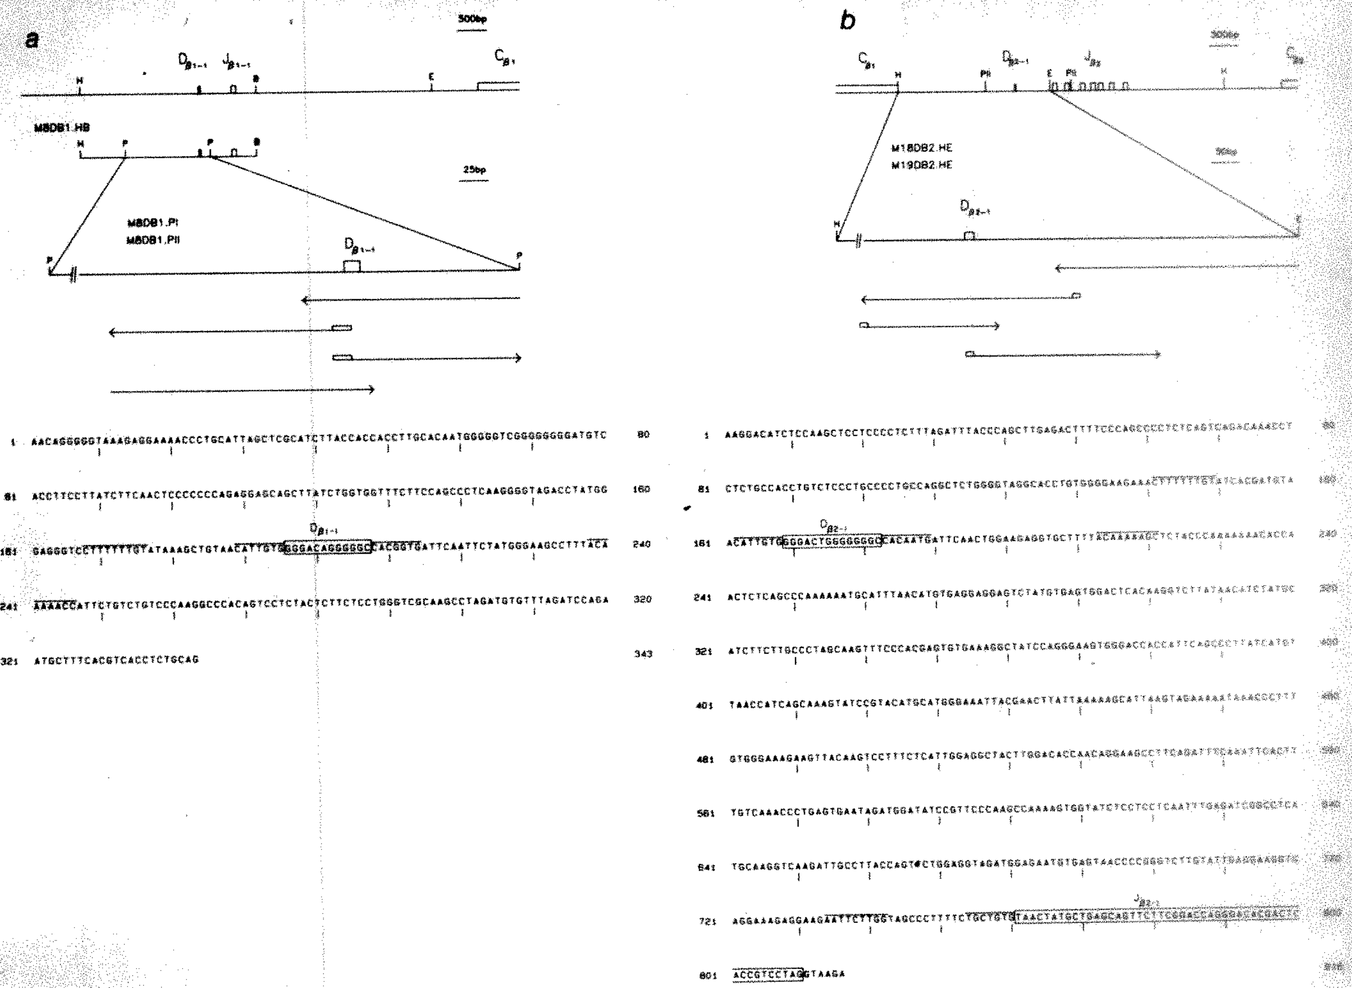

Fig. 1 Nucleotide sequences of germ-line $D_{\beta1\text{-}1}$ and $D_{\beta2\text{-}1}$ gene segments. *a*, The $D_{\beta1\text{-}1}$ subclones sequencing strategy and sequence. *b*, The $D_{\beta2\text{-}1}$ subclones, sequencing strategy and sequence. The sequence from position 410 to position 844 had been previously determined on both strands[23]. The coding regions of the D_β and J_β joining segments are boxed, and the 5′ and 3′ heptamer and nonamer recognition signals are overlined. Sequences were obtained by subcloning restriction fragments into the vectors M13mp8, M13mp18 and M13mp19 (ref. 47) and sequenced using the dideoxynucleotide method[48], as modified by E. Strauss (unpublished). Synthetic oligonucleotides complementary to mouse genomic sequences were utilized as sequencing primers in some cases. The positions of these primers are indicated by the open box at the ends of the arrows. Restriction enzyme sites are abbreviated as follows: B, *Bam*HI; E, *Eco*RI; H, *Hin*dIII; P, *Pst*I; PII, *Pvu*II.

to form part of the variable region of the 86T1β cDNA clone[19]. In addition, the coding sequences for these D_β gene segments are similar to some immunoglobulin D_H gene segments (Fig. 2*a*). We will denote the *D* gene segment to the 5′ side of the $J_{\beta1}$ gene cluster as $D_{\beta1\text{-}1}$ and the *D* gene segment to the 5′ side of the $J_{\beta2}$ gene cluster as $D_{\beta2\text{-}1}$. The $D_{\beta1\text{-}1}$ gene segment is located 647 base pairs (bp) upstream from the 5′-most germ-line $J_{\beta1}$ gene segment (Fig. 1*a*; M.K., R.H., E.S., unpublished results), while the $D_{\beta2\text{-}1}$ gene segment is located 578 bp upstream from the 5′-most germ-line $J_{\beta2}$ gene segment (Fig. 1*b*). Because the murine immunoglobulin heavy chain locus also has a D_H gene segment, D_{Q52}, found 696 bp 5′ to its *J* gene cluster[11], there may be some functional significance of a single *D* gene segment closely linked to the *J* gene cluster in the germline.

There probably are additional D_β gene segments that have not yet been located in the germ-line DNA. With the exception of three nucleotides missing from the 3′ end, the coding and 5′ flanking sequences of the $D_{\beta2\text{-}1}$ gene segment are identical to the D_β gene segment expressed in the TM86 cDNA clone. We believe, therefore, that this cDNA clone includes the $D_{\beta2\text{-}1}$ gene segment. The 86T5 cDNA D_β gene segment is also shorter than the $D_{\beta1\text{-}1}$ gene segment by three base pairs, and in addition it has one difference at its 3′ end and one in the 5′ flanking region out of the 90 base pairs compared. It is therefore possible that the 86T5 D_β gene segment is derived from a different germ-line gene; comparable similarity between members of a family is seen in several immunoglobulin D_H gene segment families[25]. Alternatively, somatic mutation or polymorphism between inbred mouse strains could account for these differences. In addition, the D_β gene segment in 2B4.71, a cDNA clone from a helper T-cell hybridoma[21] specific for cytochrome c, is different from the three other D_β gene segments. Thus the two D_β gene segments identified each lie to the 5′ side of their corresponding J_β gene segment clusters and it appears likely that additional D_β gene segments will lie to the 5′ side of the $J_{\beta1}$ gene cluster.

Structure of germ-line D_β

Figure 2 shows the germ-line $D_{\beta1\text{-}1}$ and $D_{\beta2\text{-}1}$ coding and flanking sequences aligned with each other, with the D_β sequences from several β-chain cDNA clones, and with some representative sequences from the immunoglobulin heavy chain gene family. The $D_{\beta1\text{-}1}$ gene segment has 12 nucleotides while the $D_{\beta2\text{-}1}$ gene segment has 14 nucleotides (Fig. 2*a*) and they therefore resemble murine D_H segments, which range in size from 10–23 nucleotides[25]. The sequences of both the $D_{\beta1\text{-}1}$ and $D_{\beta2\text{-}1}$ gene segments are G-rich and they are similar at 10 out of 12 nucleotides compared; they are also similar to the presumed D_H gene segment found in the heavy chain of some oxazalone-binding immunoglobulins[26], and to the D_H region found in the heavy chain of the 18-81A-2 Abelson murine leukaemia virus (A-MuLV)-transformed cell line[27] (Fig. 2*a*). Fig. 3 Junctional and N-region diversity in β-chain rearrangement. Boxed regions indicate gene segment junctions. *a*, The cDNA clone TM86, compared with germline gene segments $D_{\beta 21}$ and $J_{\beta 2\text{-}5}$. The last three nucleotides of $D_{\beta 2\text{-}1}$ and the first two nucleotides of $J_{\beta 2\text{-}5}$ have been deleted in the joining event, and one nucleotide of TM86 (a C at position 20) is not encoded by either germline gene segment. *b*, The cDNA clone 86T1, compared with germline gene segments $D_{\beta 1\text{-}1}$ and $J_{\beta 1\text{-}3}$. One nucleotide at the 5' end of the $D_{\beta 1\text{-}1}$ gene segment has been deleted or substituted in the D_β–J_β joining. One nucleotide of 86T1 (a T at position 20) is not encoded by either the $D_{\beta 1\text{-}1}$or $J_{\beta 1\text{-}3}$ gene segments. No nucleotides were delected from the $J_{\beta 1\text{-}3}$ gene segment during the D_β–J_β joining event; the nucleotide 5' of the first T is a G present in the joining sequence.

previously observed that the D_β gene segment in the 2B4.71 cDNA clone is similar to the immunoglobulin D_H gene segment D_{Q52} (ref. 21). It has also been observed that the coding and flanking regions of the mouse and human $D_{\beta 1\text{-}1}$ gene segments are highly conserved[28]. The significance of the similarity observed between the mouse D_β and D_H gene segments is unclear. Figure 2*b* shows the 5' flanking regions of the $D_{\beta 1\text{-}1}$ and $D_{\beta 2\text{-}1}$ gene segments aligned with each other, with the 86T5 and TM86 β cDNA clones and with representative members of four murine D_H gene segment families[25]. Figure 2*c* shows the aligned 3' flanking sequences of the $D_{\beta 1\text{-}1}$ and $D_{\beta 2\text{-}1}$ gene segments. These 3' flanking sequences are also aligned with immunoglobulin V_H sequences as opposed to D_H gene segments, since the V_H gene segments also have 23-base pair spacers in their 3' joining signals. Gaps were inserted to maximize the similarity between the sequences. The 5' flanking sequences of the $D_{\beta 1\text{-}1}$ and $D_{\beta 2\text{-}1}$ gene segments are similar at 35 out of 47 positions compared. The $D_{\beta 1\text{-}1}$ and $D_{\beta 2\text{-}1}$ 3' flanking sequences share 31 out of 60 nucleotides compared. Comparison of the far-flanking regions of the $D_{\beta 1\text{-}1}$ and $D_{\beta 2\text{-}1}$ gene segments indicates that they share the highest similarity at the recognition signals. Aside from these signals, these flanking regions have little sequence similarity with either the 5' flanking region of D_H gene segments or the 3' flanking region of V_H gene segments.

D_β recognition signals

As was noted by Early *et al.*[7], the 12 and 23 nucleotide spacer sequences of immunoglobulin joining recognition sequences correspond to approximately one and two turns of the DNA helix, respectively. An interesting feature of the recognition sequences for immunoglobulin V_H and V_L gene rearrangements is that the one-turn recognition sequence is always joined to a two-turn recognition sequence. This rule of one- and two-turn joining is followed in the β-gene family of T-cell receptors as well (Fig. 2*b*, *c*)[21–23]. The V_β and J_β gene segments have two-turn and one-turn recognition signals, respectively, and the D_β gene segment has a one-turn recognition signal to its 5' side and a two-turn recognition signal to its 3' side. This organization of recognition sequences permits several types of V_β gene formation consistent with the one- to two-turn joining rule: V_β gene segments may join directly to J_β gene segments, V_β–D_β–J_β joining may occur involving a single D gene segment, or two or more D_β gene segments could join between the V_β and J_β gene segments. Thus, the organization of the recognition sequences for the β-gene family should permit additional combinatorial joining possibilities to be employed in the generation of V_β diversity.

Junctional and N-region diversity

Junctional diversity in immunoglobulin variable regions is caused both by the imprecise joining of V_L and J_L or V_H, D_H, and J_H gene segments that can lead to the deletion of nucleotides from the ends of these gene segments[10–12] and by the addition of nucleotides at the junction between V_H and D_H or D_H and J_H gene segments that are not found in either of the germ-line counterparts (N-region diversity)[11,13]. Analysis of the coding regions of germ-line D_β and J_β gene segments indicates that both mechanisms for generating junctional diversity occur in the β-chain of the T-cell receptor. Figure 3*a* compares the published sequence of the TM86 cDNA clone[19], which contains the $D_{\beta 2\text{-}1}$ sequence joined to the $J_{\beta 2\text{-}5}$ gene segment, to the germ-line sequences of $D_{\beta 2\text{-}1}$ and $J_{\beta 2\text{-}5}$. In the TM86 cDNA three bases have been deleted from the 3' end of the $D_{\beta 2\text{-}1}$ gene segment, and two bases have been deleted from the 5' end of the $J_{\beta 2\text{-}5}$ gene segment. In addition, N-region diversity is indicated by the presence of a cytidine nucleotide not found at the end of either germ-line gene segment that is present at the D–J boundary. A second possible example of both types of diversity can be found by comparing the published sequence of the 86T1 cDNA clone[19] that contains a complete variable region gene segment joined to the $D_{\beta 1\text{-}1}$ and $J_{\beta 1\text{-}3}$ (M.K. and R.H., unpublished) gene segments (Fig. 3*b*). Although the central ten base pairs of the 86T1 D_β gene segment are identical to the germ-line $D_{\beta 1\text{-}1}$ sequence, the end nucleotides have been altered. The first nucleotide of the $D_{\beta 1\text{-}1}$ gene segment at the V_β–D_β boundary has been deleted or substituted, while the last nucleotide at the D_β–J_β boundary has been replaced with a different base. In this latter example, it is also possible that no deletions or additions occur, but instead a D_β gene segment that is slightly different

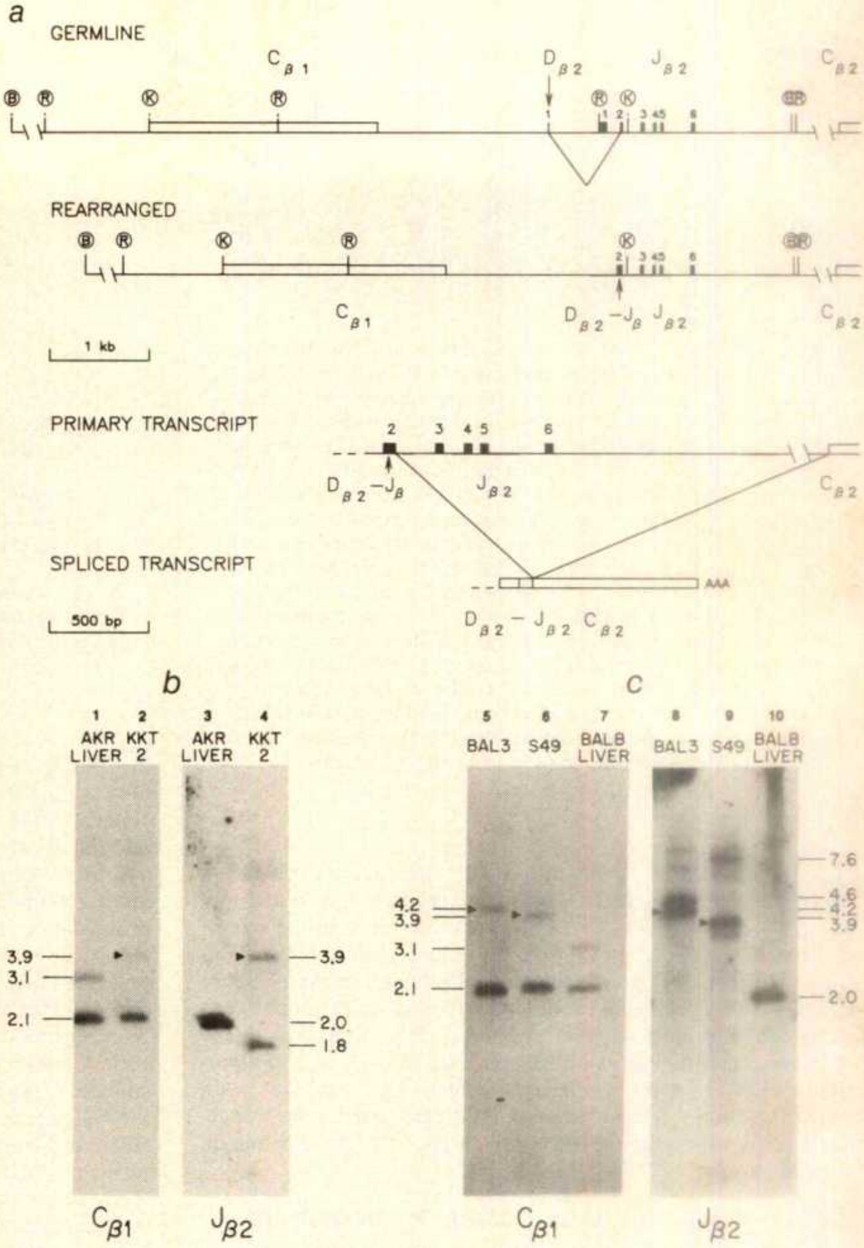

Fig. 4 D_β–J_β joining in T-cell tumour DNA. Southern blots[53] of *Eco*RI digested DNA were hybridized with a $C_{\beta 1}$ cDNA clone[54] and a fragment from a germ-line cosmid clone that contains $J_{\beta 2}$ sequences[23]. Conditions used for the Southern blots have been described previously[55]. *a*, A model for the rearrangement and expression of the partially joined (D_β–J_β) genes. The C_β genes are depicted as open boxes; the separate exons of these genes are not shown. The $D_{\beta 2}$ and $J_{\beta 2}$ gene segments are numbered and are shown as vertical lines or filled boxes. Some relevant restriction sites for the Southern blot analysis are indicated. B, *Bam*HI; K, *Kpn*I; E, *Eco*RI. The rearrangement presented in the figure joins the $D_{\beta 2\text{-}1}$ to the $J_{\beta 2\text{-}2}$ gene segment eliminating the third *Eco*RI site as well as $J_{\beta 2\text{-}1}$ and leading to the rearranged fragments described in the text. Rearrangement to other $J_{\beta 2}$ gene segments is also possible. The scale used to depict the transcripts is expanded twofold. The dotted lines at the 5′ end reflect uncertainty about the structure of this part of the transcript. *b*, Hybridization of the $C_{\beta 1}$ cDNA (lanes 1, 2) and $J_{\beta 2}$ fragment (lanes 3, 4) to AKR strain tumour KKT-2 and to AKR liver DNA. *c*, Hybridization of the $C_{\beta 1}$ (lanes 5–7) and $J_{\beta 2}$ (lanes 8-10) probes with DNA from the BALB/c tumours BAL3 and S49 and with BALB/c liver DNA. In both *b* and *c* the filter was first hybridized with $C_{\beta 1}$ the probe was removed, and the same filter was then hybridized with the $J_{\beta 2}$ probe. The arrows denote the identically-sized rearranged fragment that could be detected by both probes. The estimated sizes in kilobases of the hybridizing fragments are indicated.

from the $D_{\beta 1\text{-}1}$ gene segment may be present in 86T1. It is also possible that inter-strain sequence polymorphisms can account for these differences, since the germ-line sequences are from B10 mice and in this case the cDNA sequence is from BALB/c mice. Because the only differences are at the boundaries between the joined gene segments, we consider these latter possibilities to be less likely.

D_β–J_β joining without *V*–*D*–*J* joining

A productive DNA rearrangement is defined as one in which the *V*, *D* and *J* (or *V*–*J*) joining process occurs in such a way that a functional polypeptide chain can be expressed. In immunoglobulin genes a variety of nonproductive rearrangements may occur, including incomplete rearrangements of D_H and J_H gene segments joined together without a V_H gene segment. Such incomplete heavy chain rearrangements occur frequently in immature B cells[29,30] but are also found in some mature B cells[11,31] and T cells as well[12], and are thought to be the first step in the assembly of heavy-chain variable region genes. The β-gene segments may undergo *D*–*J* rearrangements in the absence of V_β joining in a manner similar to their immunoglobulin counterparts. We have characterized the β-gene rearrangements in a large number of T-cell lines, hybridomas, and tumours (M.K., J. Goverman, M. Malissen, R.H., manuscript in preparation) and have observed several cases in which the DNA from T-cell tumours have undergone an apparent D_β–J_β joining. For example, when germ-line DNA is digested with the restriction enzyme *Eco*RI and hybridized with a $C_{\beta 1}$ cDNA probe, there are two hybridizing fragments of 2.1 and 3.1 kilobases (kb). The 3.1 kb fragment is at the 3′ end of the C_β gene beginning close to the translational stop codon and ending just 5′ to the first $J_{\beta 2}$ gene segment[23] (Fig. 4*a*). In the T-cell tumours S49, BAL3, and KKT-2, the 3.1 kb fragment at the 3′ end of the $C_{\beta 1}$ gene is replaced by a larger fragment that is either 3.9 kb (S49 and KKT-2) or 4.2 kb (BAL3) (Fig. 4*b*, *c*). Hybridization of the same filters with the $J_{\beta 2}$ probe reveals two rearranged fragments in each case, including one fragment identical in size to the one detected with the $C_{\beta 1}$ probe. Southern blots of DNA from these tumours were generated from DNA digested with *Bam*HI and hybridized with the $C_{\beta 1}$ and $J_{\beta 2}$ probes. Digestion of germ-line DNA with this enzyme will generate a single fragment that should hybridize with both probes (Fig. 4*a*). In the DNA from each of the tumours one of the fragments hybridizing with the $J_{\beta 2}$ probe and the only fragment hybridizing with the $C_{\beta 1}$ cDNA are identically sized and approximately 1,000 bp smaller than the germ-line fragment (M.K., R.H., unpublished observations). We therefore conclude that the rearrangements 3′ to the $C_{\beta 1}$ gene in these tumours are small deletions. Since this deletion spans the *Eco*RI site just to

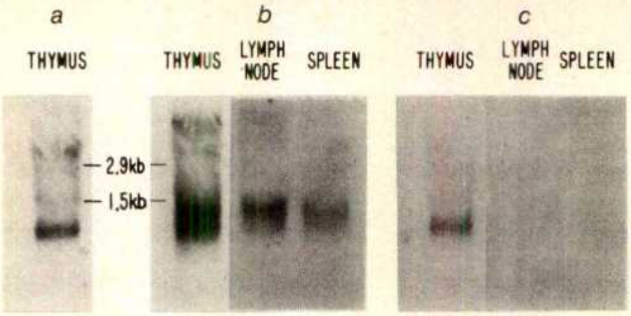

Fig. 5 Hybridization of D_β and C_β probes to RNA from lymphoid tissues. The probes are as follows: *a*, T6 synthetic oligonucleotide; *b*, C_β cDNA clone; *c*, T5 synthetic oligonucleotide. RNA was prepared from thymus, spleen, and lymph node of 4-week-old DBA 1/J female mice by homogenization of the tissues in guanidinium thiocyanate followed by centrifugation through a cushion of CsCl[56]. Northern blots of total cell RNA and hybridization with a C_β probe were performed as described previously[57]. Hybridization with oligonucleotides was done at room temperature with end-labelled synthetic probe at a concentration of 0.5 pmol ml^{-1}. The blots were washed in 2×SSC/0.1% SDS at room temperature followed by washing in the same solution at 37 °C. One filter was used in *a*, *b* and *c*; following hybridization and exposure to film, the probe was removed by stringent washing before retesting with a second probe. The migration distance of *Escherichia coli* ribosomal RNA molecular weight markers is indicated. Other markers included mouse 28+18S ribosomal RNA (4.8 and 1.9 kb) and MS2 phage RNA (3.6 kb).

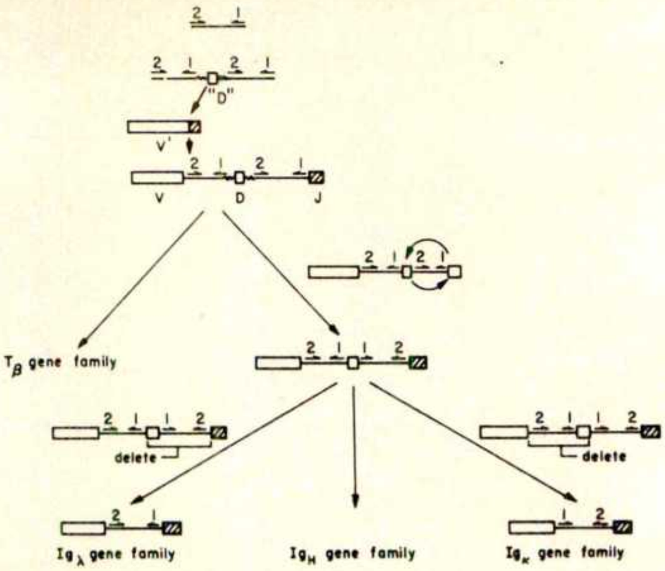

Fig. 6 A model for the evolution of the immunoglobulin and β T-cell receptor gene families. The number 1 represents the one-turn recognition signal; the number 2 represents the two-turn recognition signal.

the 5′ side of the $J_{\beta2}$ gene cluster, the most likely explanation for these events is that the $D_{\beta2\text{-}1}$ gene segment has joined to a $J_{\beta2}$ gene segment (Fig. 4*a*). The slight difference in the size of the rearranged fragment in different tumours could reflect joining to different $J_{\beta2}$ gene segments. We have similar evidence that $D_{\beta1\text{-}1}$ to $J_{\beta1}$ joining events can occur as well (unpublished data). Thus it appears likely that the $D_{\beta1\text{-}1}$ and $D_{\beta2\text{-}1}$ gene segments do participate in both complete (V_β–D_β–J_β) and partial (D_β–J_β) DNA rearrangements. By analogy with immunoglobulin heavy-chain genes, these partial rearrangements may represent the first step in β-chain variable region gene assembly.

D_β–J_β transcription not using V_β promoters

Northern blot analyses have been carried out on RNA from thymus, lymph node, and spleen using both a C_β probe (Fig. 5*b*) and the oligonucleotides T5 and T6 (Fig. 5*a*, *c*). The C_β probe detects two species, approximately 1.3 and 1.0 kb in size, when hybridized to total RNA from the thymus. Similar results have been obtained with poly(A)$^+$ RNA (M.K., G.S., unpublished observations). Spleen and lymph node RNA have a single C_β hybridizing transcript of 1.3 kb. When RNA from these three lymphoid tissues is hybridized with either the T5 or T6 oligonucleotide, only the 1.0 kb thymus RNA is detected. It is important to note that both T5 and T6 are complementary to 6 bases of D_β coding sequences and 34 bases of 5′ flanking sequence. These two probes therefore do not hybridize with fully rearranged V_β–D_β–J_β genes since these rearrangements eliminate the 5′ D_β flanking sequence. Because the probes also do not cross-hybridize with each other, we conclude that at least two D_β gene segments contain 5′ promoters that permit expression in thymus: one is the $D_{\beta2\text{-}1}$ gene segment and the second is the $D_{\beta1\text{-}1}$ gene segment or a highly similar *D* gene segment such as the one found in the 86T5 cDNA clone. It has recently been demonstrated that each immunoglobulin D_H gene segment also has a promoter located in the 5′ flanking DNA[32].

We have hybridized both the C_β probe and the D_β oligonucleotide probes to RNA from the S49 and KKT-2 tumours that are believed to have joined $D_{\beta2}$–$J_{\beta2}$ gene segments. The KKT-2 tumour has only a 1.0 kb transcript that hybridizes with both the T6 D_β oligonucleotide and a probe specific for the 3′ end of $C_{\beta2}$. Several other T-cell tumours and T-cell hybridomas contain 1.0 kb transcripts that hybridize with both C_β probes and the T6 oligonucleotide. However, RNA from S49 does not hybridize with either oligonucleotide, and it contains a 1.3-kb but not a 1.0-kb transcript when hybridized with the C_β cDNA probe (M.K., unpublished observations).

Based on the blot-hybridization and nucleotide sequence data presented here and the partial nucleotide sequences of the TM86 and 86T5 cDNA clones, we have presented a model for the rearrangement and expression of the D_β gene segments and their 5′ flanking sequences (Fig. 5*a*). D_β–J_β rearrangement may stimulate transcription from a promoter located 5′ to several of the D_β gene segments. This transcript is 1.0 kb long, polyadenylated, and contains a joined D_β–J_β gene segment spliced to the exons normally used in the C_β gene. Although we cannot formally rule out transcription from this promoter in the absence of gene rearrangement, it should be noted that the KKT-2 tumour has no germ-line $J_{\beta2}$ clusters (Fig. 4*c*) and that a transcript derived from a promoter 5′ to the $D_{\beta2\text{-}1}$ gene segment that includes the intron between $D_{\beta2\text{-}1}$ and $J_{\beta2\text{-}1}$ as well as the exons of $C_{\beta2}$ would be at least 1.6 kb. No transcript of this length has been detected with any of the probes employed. The prevalence of the 1.0 kb transcript in thymus, as opposed to lymph node and spleen, would suggest that many of the immature cells in this tissue have undergone a partial (D_β–J_β) rearrangement. However, as some functional mature T lymphocytes have a 1.0-kb transcript that hybridizes with the T6 oligonucleotide (M.K., unpublished), there is probably a low level of 1.0-kb transcript in lymph node and spleen that could not be detected on our blots.

Immunoglobulin gene expression in B lymphocytes is thought to result from gene rearrangements that bring into proximity two widely separated elements: a promoter sequence located 5′ to the *V* gene segments[33,34] and an enhancer sequence located in the intron between the *J* gene segments and the *C* genes[35–39]. In the case of the D_β–J_β transcript, however, the location of the promoter relative to any postulated enhancer would not be greatly affected by the relatively small deletions involved in the D_β–J_β joining we have described. Therefore the means by which D_β–J_β joining might stimulate transcription are unknown. Furthermore, Northern blots of RNA from the S49 tumour indicate that rearrangement is necessary but may not be sufficient for transcription. Currently, we are further characterizing the D_β–J_β

DNA rearrangements and D_β transcripts in a number of T-cell tumours in order to understand better the relationship between the rearrangements and the 1.0 kb C_β transcripts that we have described.

Are D_β–J_β transcripts translated?

In the immunoglobulin gene families, transcripts have been described that originate from unrearranged κ[40] and heavy-chain genes[41] or from incompletely rearranged (D_H–J_H) heavy-chain gene segments[27,41]. Some of the RNA molecules do not give rise to detectable polypeptides and are referred to as sterile transcripts[27,42]. These sterile transcripts might not be physiologically significant, or else the RNA molecule itself might have some regulatory function. Similar speculations apply to the 1.0-kb transcripts containing D_β gene segments. In addition, it is also possible that these D_β–J_β transcripts encode functional polypeptides. If the 1.0-kb transcripts use the entire C_β gene and the same 3′ end as is found in the 1.3-kb C_β RNA, then about 100–200 nucleotides remain for the D_β coding region and its 5′ flanking sequence. The nucleotide sequences flanking the $D_{\beta1\text{-}1}$ and $D_{\beta2\text{-}1}$ gene segments have open reading frames for more than 50 codons. A methionine codon that is in frame with the germ-line D_β gene segments is located 5′ to both $D_{\beta1\text{-}1}$ and $D_{\beta2\text{-}1}$ (data not drawn for $D_{\beta2\text{-}1}$). Moreover, the $D_{\beta1\text{-}1}$ flanking sequence has a signal sequence for membrane insertion of a nascent polypeptide[43] 136 nucleotides 5′ to the D_β gene segment (Fig. 1*b*). A possible signal sequence is also located following the methionine codon 5′ of $D_{\beta2\text{-}1}$ (data not shown). Alt and co-workers have demonstrated that most immunoglobulin D_H gene segments have open reading frames in their 5′ flanking sequence that begin with a methionine codon followed by a hydrophobic leader sequence. They have also demonstrated that transcripts derived from partial D_H–J_H rearrangements give rise to truncated C_μ-containing polypeptides[32]. We therefore believe that the D_β–J_β transcripts will in at least some cases give rise to truncated β polypeptides. The function, if any, of these truncated polypeptides is unknown. Because it has been proposed that the synthesis of complete heavy chain and light chain polypeptides derived from productively rearranged genes prevents further *V* gene rearrangement[40,44], we might speculate that the truncated C_μ and C_β polypeptides will in a similar fashion somehow stimulate or facilitate the *V* gene rearrangement process. It is also possible that these truncated proteins provide a stimulatory signal for cell growth similar to that provided by antigen bound to the intact receptor. Alternatively they might function at the cell surface with regard to the development of the repertoire of receptors via network interactions.

Evolution of gene rearrangements

It has been proposed that the ability of the antibody and T-cell receptor gene families to undergo DNA rearrangements evolved from the insertion of a transposable element into a primordial uninterrupted *V* gene exon[6,45] (Fig. 6). This theory proposed the existence of a transposon with asymmetric inverted repeats similar to those found in the joining sequences of the contemporary antigen-receptor gene families. If inserted in the genome, duplication of this transposon along with a short stretch of flanking sequence would lead to a more complex transposon containing a proto-*D* gene segment (Fig. 6). Subsequent insertion of this transposon into a primordial *V* gene would generate a gene segment organization, at least with respect to joining sequences, that is similar to that of the β genes. Duplication of this locus would lead to two separate gene families: the β-chain gene family and the immunoglobulin gene family. As shown in Fig. 6, an inversion bounded by the two right-hand inverted repeats could generate the precursor of the heavy chain gene family. As outlined previously[45], further duplications of this heavy chain gene precursor could have occurred to create precursors of all three immunoglobulin gene families. A deletion on the right hand or 3′ end of the transposon as indicated in Fig. 6 generates the proto-λ gene family with its organization of joining signals. This may have occurred via homologous recombination between these signals. A similar deletion at the 5′ end could give rise to the κ gene family.

This model can account for some of the unique features of variable region genes. The known genes encoding antigen receptors on B and T lymphocytes, cell-surface molecules of the major histocompatibility complex (MHC), β_2-microglobulin and some other cell-surface proteins associated with the immune system, are believed to have evolved in part from a primordial exon that encoded an immunoglobulin-like domain[46]. With the exception of the variable region genes, each domain in these proteins having an immunoglobulin structure is encoded by a single exon. The insertion of a transposon into a primordial variable region gene can account for the fact that all the *V* gene families are split into several exons at a similar location. The theory accounts for the presence of a *D* gene segment in only two of the four antigen-receptor gene families and also explains the different configurations of DNA rearrangement signals in these families. While the evolutionary history outlined above implies that the β-chain gene family arose first, several other pathways beginning with insertion of a slightly different transposon are also possible[45]. Finally, this theory proposes a relatively simple explanation for the evolution of the DNA rearrangement signals in that it proposed these signals evolved from the inverted terminal repeats of a mobile DNA sequence but it remains unclear how these signals and the proteins that recognize them became adapted for the highly regulated rearrangements of the immune system.

This work was supported by grant AI 17565 from the NIH and by a grant from T-cell Sciences, Inc. We thank Dr Irving Weissman, Stanford University, for providing T-cell tumours, Dr Roger Perlmutter for helpful and stimulating discussions, and Dr Suzanna Horvath and Marilyn Seibel for synthesis of the oligonucleotides. We also thank Tim Hunkapiller, Astar Winoto, Drs Rick Barth, Joan Goverman, Joan Kobori, Bernard Malissen, Marie Malissen and Martha Zuniga for critique of the manuscript, Dr Marie Malissen for providing the cosmid clone and plasmid subclones, Debbie Maloney for technical assistance, and Bernita Larsh for preparation of the manuscript.

Note added in proof: While this paper was in the press, the sequence of the $D_{\beta1\text{-}1}$ gene segment and the presence of this gene segment in the 86T1 and 86T5 cDNA clones was reported by Kavaler *et al.*[58].

Apparent discontinuous transcription of *Trypanosoma brucei* variant surface antigen genes

David A. Campbell, Deborah A. Thornton & John C. Boothroyd

Department of Medical Microbiology, D-305 Fairchild Building, Stanford University School of Medicine, Stanford, California 94305, USA

The repeated mini-exon sequence that encodes the first 35 base pairs of all variant surface antigen mRNAs of Trypanosoma brucei *directs the synthesis of a discrete 137-nucleotide transcript. It thus seems that variant surface antigen mRNAs are transcribed discontinuously, and we present two alternative models for how this might occur.*

THE ability of African trypanosomes to establish chronic infections in their mammalian hosts depends on a highly developed system of antigenic variation, whereby individual members of the parasite population change the composition of their surface coat[1–3]. This antigenic variation is controlled at the level of gene expression[4,5], each trypanosome possessing a large repertoire of genes (estimated at over 100; refs 6, 7) coding for the antigenically distinct variant surface glycoproteins (VSGs) which comprise the coat. At any one time and on any one trypanosome, only one species of VSG can be detected[8], suggesting that mutual exclusion operates between the VSG genes. Activation of VSG genes occurs by a two-step process requiring first the duplication and transposition of a silent basic copy (BC) of the gene into one of a few telomeric expression sites by a process equivalent to gene conversion, then selection of the expression site over others for transcription[9–15]. The extra copy of the gene thus produced is called the expression-linked copy (ELC). The so-called 'non-duplication-activated' VSG genes described by others probably represent genes which had already undergone the first step in activation (that is, gene conversion into an expression site) before the variants were isolated for study. Although the structure of expression sites and the sequences involved in the gene conversion event have been identified for some variants[16–19], little is known about the second step, particularly how activation occurs and how the mutual exclusion operates between the different expression sites.

Recently, a major clue to this problem has come from the finding that the 5′ 35 nucleotides of VSG mRNAs are not contiguously encoded with the protein-coding portion of the gene[13], and that this spliced leader segment is identical for different VSG mRNAs regardless of which telomeric expression site they occupy[14]. The genomic location of the 35-base pair (bp) mini-exon coding for the spliced leader has recently been reported to be a 1.35-kilobase pair (kb) segment tandemly repeated 100–200 times (as one or more clusters) at an unidentified locus in the genome but at least 30 kb upstream of the active VSG gene[20,21]. Two other important observations concerning the spliced leader are that it is detected on many RNA molecules of varying size in blot analyses using RNA from different life stage forms of *Trypanosoma brucei* (ref. 21 and M. Parsons *et al.*, personal communication) and that homologous sequences have been detected in the genomes of related species and genera[22].

Several models have been proposed to explain how a contiguous mRNA is produced from such an unusual arrangement of exons[20–23] and how the activity of different expression sites is regulated. These have included chromosome end exchange with splicing of very long transcripts, and discontinuous transcription whereby the mini-exon and ELC are flanked by their own initiation and termination sites. To determine how VSG mRNAs are produced and processed, we have studied the 1.35-kb repeats and identified their transcriptional products.

Molecular cloning of a mini-exon repeat

To enable nucleotide sequence analysis of the mini-exon repeat, recombinant plasmids containing individual repeats were generated. This was initially done using a *Pvu*II digest of the genomic DNA of *T. brucei* as this enzyme has been reported to release the mini-exon-containing portion of the repeat as a discrete band at ~720 bp[21]. Such a band was excised from an agarose gel, the DNA purified by electroelution[24] and ligated into the *Pvu*II site of the plasmid vector pBR322 (ref. 25). A sample of this same excised material was radiolabelled by nick-translation[26] and used as a probe in colony hybridization[27], thereby identifying recombinants containing repetitive DNA. Four plasmids thus identified were further characterized and three were found to contain indistinguishable inserts with at least one *Rsa*I site. As the mini-exon should include an *Rsa*I site, nucleotide sequence analysis in the vicinity of this site was performed on one of the plasmids (pMEP.1). The strategy and sequence obtained are shown in Figs 1 and 2, respectively. This demonstrated unambiguously that pMEP.1 contains a portion of the mini-exon repeat.

To obtain a recombinant plasmid containing an insert representative of the complete 1.35-kb repeat, a ligation was performed using the 1.35-kb fraction of trypanosome genomic DNA digested with *Sau*3A and the plasmid vector pAT153 (ref. 28) digested with *Bam*HI. Recombinants were screened with the

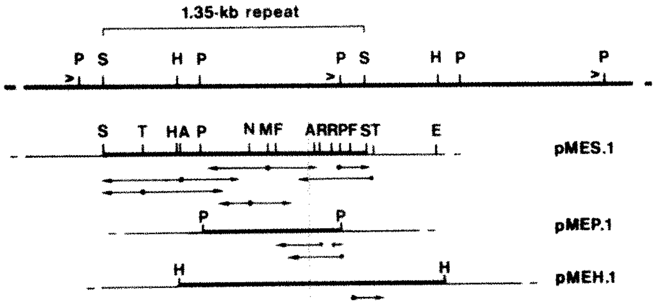

Fig. 1 Restriction maps and sequencing strategies for mini-exon-containing plasmids. The top line of the figure represents a restriction map for the genomic cluster of 1.35-kb tandem mini-exon repeats as deduced from Southern blot analysis (data not shown). The rightward-pointing arrowheads represent the approximate position of the 35-bp mini-exon sequence; beneath this are the recombinant-containing portions of this genomic region as cloned in the plasmid vectors pAT153 (pMES.1 and pMEH.1) and pBR322 (pMEP.1; see text). The restriction sites used in the nucleotide sequencing (by the chemical modification method of Maxam and Gilbert[43]) are shown for each insert. The arrows with solid circles indicate the labelled sites and the region over which unambiguous sequence information was obtained. Restriction sites: A, *Acc*I; E, *Eco*RI; F, *Hin*fI; H, *Sph*I; M, *Mlu*I; N, *Nar*I; P, *Pvu*II; R, *Rsa*I; S, *Sau*3A; T, *Taq*I.

Fig. 2 Nucleotide sequence of a complete 1.35-kb mini-exon repeat. The nucleotide sequence of the sense strand of pMES.1 is presented with numbering from the 5′-end of the 35-bp mini-exon, which is boxed. The restriction sites used in the cloning (see Fig. 1) are underlined and annotated. The *Sau*3A site (GATC) used in cloning the insert is duplicated at the beginning and end of the sequence. The thickly underlined segment represents the 17-nucleotide sequence for which a complementary oligonucleotide was synthesized and used in subsequent experiments (see Figs 3 and 5). The arrow between positions 137 and 138 indicates the 3′-terminus of mini-exon-derived RNA as described in the text.

*Pvu*II insert of pMEP.1 and after preliminary restriction mapping, one (pMES.1) was characterized further and found to contain an apparently complete 1.35-kb mini-exon repeat.

Nucleotide sequence of mini-exon repeat

Using the recombinant plasmid pMES.1 and the strategy shown in Fig. 1, the complete nucleotide sequence of one repeat unit containing the mini-exon was determined. This is presented in Fig. 2 with position +1 being the first nucleotide of the mini-exon. The region from −270 to +61 was also sequenced from the independently generated plasmid pMEP.1 (see Fig. 1). The results from the two plasmids were identical in this region.

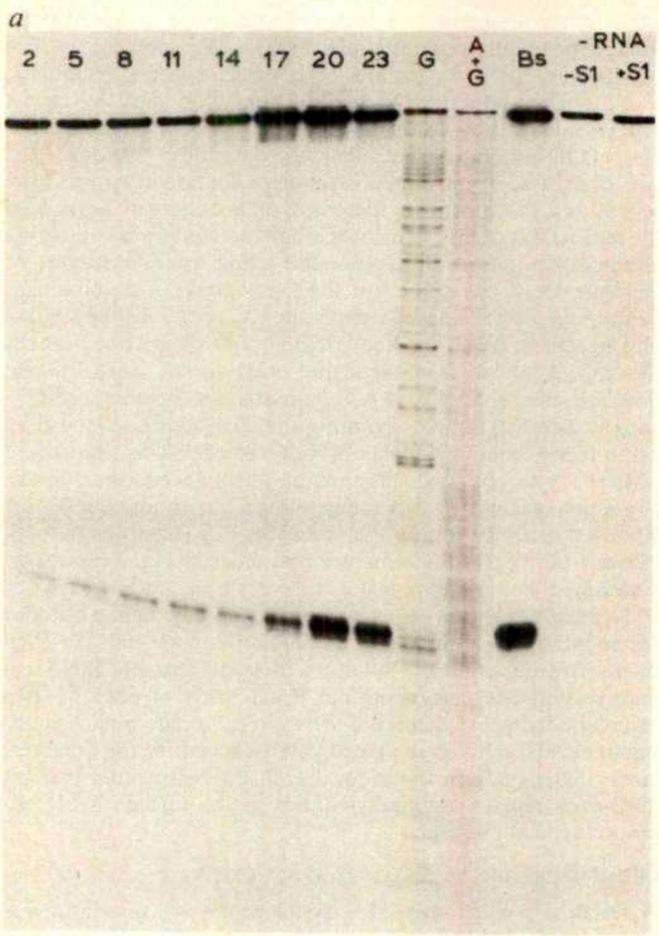
Although Southern blot analysis suggested that the repeat unit was defined by a single *Sau*3A site (refs 20, 21 and D.A.T. and J.C.B., unpublished results), the possibility remained that two closely adjacent *Sau*3A sites were contained within each repeat and that pMES.1, therefore, lacked a small portion of the repeat. To test this, a further recombinant plasmid containing a mini-exon repeat was generated using an *Sph*I digest of genomic DNA (as cloned in a bacteriophage λ recombinant containing several 1.35-kb repeats; D.A.C., unpublished results) and ligated to *Sph*I-digested pAT153. *Sph*I was known to cut the repeat once (from sequence analysis of pMES.1 and Southern blot analyses; D.A.C., unpublished results) and thus should give a fragment spanning the *Sau*3A site in question. Mini-exon-containing plasmids were identified as above and pMEH.1 was obtained, mapped and sequenced (see Fig. 1). From this plasmid, a contiguous sequence spanning the *Sau*3A site used to construct pMES.1 was obtained (data not shown), demonstrating that the sequence presented in Fig. 2 represents a complete mini-exon repeat.

To ensure that this sequence was not only complete but also representative, we compared its restriction map with the fragment sizes observed on Southern blots of genomic DNA cut with several enzymes, using the *Pvu*II insert of pMEP.1 as a radiolabelled probe (data not shown). The predominant bands obtained in each digest agreed in all cases with the fragment sizes predicted from the sequence; this demonstrated that the mini-exon repeats are highly conserved and that pMES.1 contains a typical member.

Identification of a short transcript

A testable prediction of the model proposing discontinuous transcription is that there should be detectable levels of a small RNA (that is, <1.35 kb) derived from each mini-exon repeat. One of the most sensitive methods for detecting and characterizing particular transcripts is S_1-protection[29], whereby a radiolabelled DNA probe from the region of interest is denatured and renatured in the presence of RNA; the resulting material is then digested with the single-strand-specific S_1 nuclease and the length of any protected fragments measured by gel electrophoresis and autoradiography. The DNA substrate used here was from pMES.1, extending from the [3′-^{32}P]-labelled *Pvu*II site at position +58, downstream through the *Sau*3A site (position +183), to the *Eco*RI site in the vector (see Fig. 1). This fragment was mixed with total trypanosome bloodstream-form RNA (or sucrose-gradient fractions thereof), precipitated, redissolved, denatured and renatured in conditions favouring RNA/DNA hybridization[30]. This mixture was then cooled, diluted and digested with S_1 nuclease, before electrophoresis on a 7 M urea polyacrylamide gel. The resulting autoradiogram (Fig. 3*a*) shows a single major end point of protection by total RNA which corresponds to nucleotide +137 in the sequence presented in Fig. 2. Minor bands immediately flanking this protected region may be indicative of slight heterogeneity at the 3′ end of the RNA or nonspecific digestion by S_1 nuclease at the end of the RNA/DNA duplex.

This result could be interpreted as protection by a short RNA of 137 nucleotides derived from the mini-exon repeats and/or by a longer transcript with a discontinuity at this position in the RNA/DNA duplex. To discriminate between these two alternatives, two procedures were used. The first examined the S_1-protection by different size fractions of RNA produced by sucrose-gradient centrifugation (Fig. 3*b*). Maximal protection was found in fractions 19–21, which possessed RNA with a peak size slightly larger than 4S RNA (that is, ~100–200 nucleotides), with diminishing but detectable protection in the remaining fractions (Fig. 3*a*). This strongly suggested that the protection observed with total RNA was due, at least in part, to the presence of a small RNA. The protection observed with other fractions, particularly those containing larger RNA, may be due



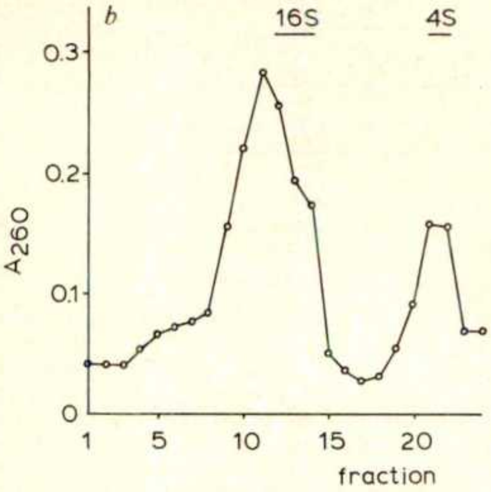


Fig. 3 *a*, S_1 nuclease mapping of the 3′-terminus of medRNA. Lanes 2–23 are reactions performed with RNA from pooled sucrose gradient fractions, as described in *b* below. Next to these are two marker sequencing reactions[43] on the labelled probe. The lane labelled Bs contains the result of a protection experiment with 50 μg of total RNA. The two controls, which contain no added RNA, are with (+S1) or without (−S1) S_1-nuclease, respectively. *b*, A_{260} profile of total trypanosome RNA fractionated by sucrose gradient centrifugation. The size markers are based on samples from each fraction analysed by electrophoresis and ethidium bromide staining (not shown).

Methods: *a*, A [3′-^{32}P]-end-labelled *Pvu*II digest of pMES.1 was re-cut with *Eco*RI to generate a uniquely end-labelled fragment corresponding to positions +59 to +183 plus 375 bp of the vector (see Fig. 1). S_1 protection was done essentially as described elsewhere[30]. Briefly, the probe was mixed with different fractions of bloodstream-form RNA, precipitated, redissolved and denatured in 80% formamide at 80 °C for 10 min. Renaturation of RNA/DNA hybrids was promoted by incubating at 45 °C for 3 h in the same buffer, before diluting with 10 vol of aqueous buffer, cooling to 30 °C and adding 35 units of S_1 nuclease. Digestion was for 30 min, after which the reactions were phenol-extracted, isopropanol-precipitated, resuspended in formamide loading buffer[43] and resolved by PAGE in a 6% polyacrylamide gel with 7 M urea[44]. *b*, A 15–30% linear sucrose gradient was prepared in 0.1 M NaCl, 1 mM EDTA, 20 mM Tris-HCl (*p*H 7.5), 0.1% SDS. About 1 mg of total trypanosome RNA was overlaid with the same buffer and the samples spun in an SW-41 rotor (Beckman) at 40,000 r.p.m. at 20 °C for 9.5 h. Fractions were collected from the bottom of the tube and the A_{260} measured. For the S_1-protection experiments, 5% of each sample was removed and pooled in groups of three (numbered by the middle fraction).

to contamination with the small RNA. Alternatively, they may be a result of protection by hybrid transcripts comprising the small RNA at their 5′ ends linked to RNA from, for example, the ELC region, by the mechanisms discussed below.

The second method to detect and size transcripts from the mini-exon repeat used Northern blot analysis[31]. For this procedure, total trypanosome RNA was resolved by polyacrylamide gel electrophoresis (PAGE) in denaturing conditions, transferred to GeneScreen membrane[32] and hybridized with a [5′-^{32}P]-labelled, synthetic oligonucleotide complementary to positions +117 to +133. This 17-mer was chosen because it excluded the mini-exon itself, which was known to give intense hybridization throughout RNA blots when used as a probe[21] and because the S_1-protection experiments indicated that it should hybridize to mini-exon-derived transcripts. Figure 4*a* shows the ethidium bromide stain of a polyacrylamide/7 M urea gel in which the major small RNA species is readily apparent. Figure 4*b* presents the autoradiogram produced after hybridizing a GeneScreen transfer of a duplicate half of this gel with the 17-mer; only one band is detected in the track containing trypanosome RNA and no signal is observed in the track containing RNA from the unrelated parasitic protozoan, *Toxoplasma gondii.* The size of the band is ~140 nucleotides based on published values for the small ribosomal RNAs of trypanosomes[33], thus confirming that the mini-exon repeats are transcribed to yield a short, discrete RNA which we have termed mini-exon-derived RNA (medRNA). With regard to its precise size, this result is, within experimental error, consistent with medRNA being 137 nucleotides long. We cannot, however, exclude the possibility that medRNA is as many as 4–5 nucleotides longer and that S_1 nuclease nonspecifically digested the 3′ end of the RNA/DNA hybrid. Note, however, that the nucleotides at positions 138 and 140 are cytosines which, as CG pairs, would be less susceptible to such action. A definite answer awaits 3′-sequence analysis of medRNA.

These results also suggest that the 5′-terminus of medRNA is at about position +1 in the mini-exon repeat. To confirm this, we used the synthetic oligonucleotide from the RNA blot analyses as a primer for reverse transcriptase extensions of medRNA. The result (Fig. 5) shows a major band co-migrating with a heterologous DNA marker of 135 nucleotides. Using a different heterologous marker (a *Hin*dIII digest of bacteriophage λ DNA), the size of this band was estimated as 133 nucleotides. This slight discrepancy is probably due to differences in base composition. Allowing for this variation, the extension has an approximate length of 134 ± 1 nucleotides. Given that the 5′-end of the primer represents position +133 of the mini-exon repeat, this result confirms that the 5′-end of medRNA corresponds to position +1, the same as that found for the spliced leader of mature VSG mRNAs[13,14]. The minor band in Fig. 5 at 138 ± 1 nucleotides may be an artefact of reverse transcriptase (for example, loop-back synthesis) or it may be indicative of a minor RNA 4 nucleotides longer than the major species. Such minor heterogeneity might be due to variation in the mini-exon repeat sequences and/or in the site of transcriptional initiation. No other major bands were observed in other loadings of this sample run for longer or shorter periods (data not shown).

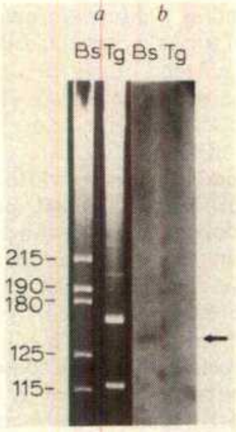

Fig. 4 Detection of the mini-exon-derived RNA. *a*, Ethidium bromide stain of electrophoretically separated trypanosome RNA. Lane Bs contains 10 μg of total RNA from bloodstream-forms of *T. brucei* (strain MITat 1.4). Lane Tg contains 10 μg of RNA from *T. gondii* as a negative control. The major bands in lane Bs are polysome-derived and their sizes in nucleotides are taken from ref. 33. The two major bands in the *T. gondii* RNA are presumably 5S and 5.8S. *b*, Autoradiograph of an RNA blot of the other half of the gel shown in *a*, containing identical samples, and having been probed with [5'-^{32}]-labelled 17-mer complementary to positions +117 to +133 of Fig. 2.

Methods: *a*, Total RNA was separated on an 8% polyacrylamide gel (1.5 mm thick) containing 7 M urea[44]. *b*, The electrophoresed RNA was electroblotted to GeneScreen membrane[32] at 4 V for 18 h at 4 °C in 25 mM Na phosphate (*p*H 6.5). The filter was prehybridized in 50% formamide, 5 × SSC (1 × SSC = 0.15 M NaCl, 0.015 M Na citrate), 1 × Denhardt's, 25 mM Na phosphate (*p*H 6.5), 0.1% SDS, 0.1% Na pyrophosphate, 100 μg ml^{-1} denatured calf thymus DNA at 30 °C for 2 h. A synthetic oligonucleotide complementary to positions +117 to +133 (see Fig. 2) was synthesized by standard means, [5'-^{32}P]-labelled by polynucleotide kinase, added to the prehybridization solution and the incubation continued with gentle shaking for 15 h at 30 °C, followed by 5 h at 22 °C. The filter was washed in four changes of 2 × SSC, 0.5% SDS for 15 min each at 22 °C. Autoradiography was at −70 °C with an intensifying screen for 6 days.

Conclusions

We have cloned and sequenced a complete copy of the 1.35-kb mini-exon repeat of *T. brucei* and identified a short RNA of 137 nucleotides as its transcriptional product. The data indicate that this repeat is a typical member of a highly conserved family—this is demonstrated further by the virtually complete agreement of the sequence presented in Fig. 2 with the partial sequence for the region from −130 to +61 recently published elsewhere[21]; the four differences (three single base changes, one insertion) are all localized to between −115 and −125. As the sequences in both cases were determined from two plasmids, the differences may be indicative of minor, but real, variation in the repeats.

In addition to the region coding for medRNA, each 1.35-kb mini-exon repeat contains about 1,200 nucleotides whose function is not clear; part of this region is presumably involved in the regulation of medRNA expression, but the remainder could be involved in some other aspect of trypanosome gene expression. Of particular note is the repetitive nature of the sequence around the *Sau*3A site, consisting of 1-, 2-, 4- and 6-nucleotide repeats (T, AT/AC, ATTT/GTTT and ACACTC, respectively). It will be interesting to determine whether these regions of the repeat are as exactly conserved as that coding for the medRNA.

The predicted sequence of medRNA can be drawn with several alternative regions of intramolecular base-pairing (data not shown). This suggests that medRNA might adopt a stable conformation with substantial secondary structure, but, as we have no data on RNase sensitivity, we cannot present a reliable structure.

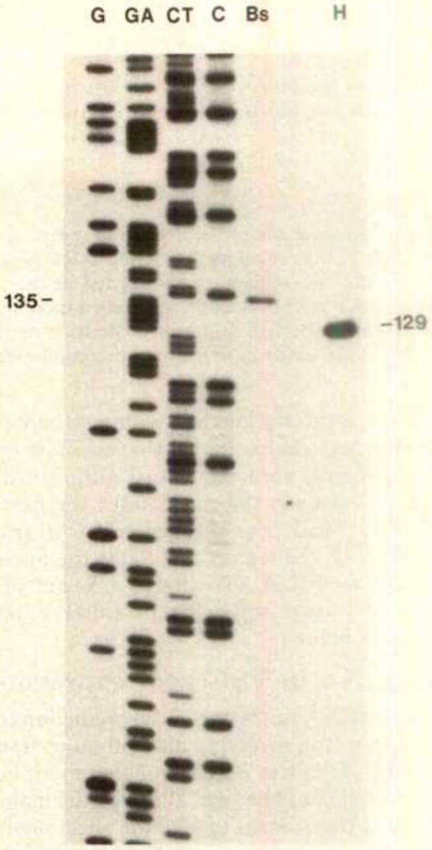

Fig. 5 Identification of the 5'-terminus of the medRNA. Polyacrylamide gel electrophoresis of the reverse transcriptase product primed off medRNA (lane Bs). Marker tracks contained standard sequencing reactions[43] of a mouse cDNA clone (provided by J. Kavaler; lanes G, A+G, C+T and T) or a [3'-^{32}P]-labelled *Hin*dIII digest of λ DNA (lane H).

Methods: The [5'-^{32}P]-labelled synthetic oligonucleotide described in Fig. 4 legend used as a primer in extension reactions using AMV everse transcriptase. About 4 μg of primer were hybridized to 20 μg of total bloodstream-form RNA in 1.2 M Na phosphate buffer (*p*H 6.8), 0.5% SDS, 12.5 mM EDTA at 21 °C for 4 h. After ethanol precipitation, the reverse transcriptase reaction was done in 50 mM Tris-HCl (*p*H 8.3), 6 mM $MgCl_2$, 1 mM dithiothreitol, 60 mM KCl, 0.1 mM dATP, dCTP, dTTP and dGTP, and AMV reverse transcriptase (50 units) at 37 °C for 1 h. The sample was ethanol-precipitated, resuspended in formamide loading dye and electrophoresed on a 7 M urea, 8% polyacrylamide gel. The dried gel was autoradiographed at −70 °C for 72 h.

The detection of medRNA raises questions about the signals directing its transcription. As noted by De Lange *et al.*[21], the octanucleotide centred at position −27 upstream of the putative initiation site for transcription consists of TATTTTTG, similar to the consensus sequence generally found at this position in eukaryotic RNA polymerase II promoters (the so-called TATA box; see ref. 34). Assuming trypanosomes are usual in their types and functions of RNA polymerase and given that the medRNA ultimately forms the 5'-end of the VSG mRNA, the finding of a putative TATA box at this position is expected. Further studies on relative drug sensitivities and 5'-cap structures are needed to confirm medRNA as an RNA polymerase II transcript. The termination site cannot be compared with the general case as too few sequences of eukaryotic transcriptional terminators have been reported to enable consensus sequences to be made.

Recently, the complete sequence of a small nuclear RNA (snR3) and its gene have been reported in yeast[32,35]. This transcription unit shows remarkable similarity to the mini-exon repeat at four critical positions (Fig. 6), the remainder of the two sequences sharing no significant homologies. First, the snR3 gene also has the octanucleotide TATTTTTG centred at position −27 relative to the start site for transcription. Second, the

Fig. 6 Nucleotide sequence of the mini-exon repeat of *T. brucei* compared with that of the small nuclear RNA (snR3) gene of yeast (from ref. 32). The two sequences are aligned at the indicated positions with position +1 in both cases corresponding to the 5′-terminus of their respective transcripts. Question marks designate functions which have not yet been confirmed.

initiation site for transcription lies within a heptanucleotide sequence which is very similar in the two genes (six out of seven bases identical). Third, both sequences, although of different overall length (137 versus 194 nucleotides for medRNA and snR3, respectively), end near the beginning of an extremely T-rich region. Finally, the region containing the putative donor splice site of the medRNA also shares a 5- out of 6-residue homology with the yeast snR3, the potential significance of which is discussed below.

Role of medRNA in VSG gene expression

The finding of medRNA fulfils one of the predictions of a model for VSG gene expression involving discontinuous transcription. However, it is not definitive because of the multiplicity of the mini-exon repeats: it could be that, although the majority of the repeats are indeed transcribed to give the short medRNA, one repeat is used in the initiation of a very long transcript including the VSG coding exon. This is a difficult possibility to exclude because pulse-chase experiments, which have been traditionally used to demonstrate precursor/product relationships, suffer from the same shortcoming—it is impossible to demonstrate that a given mini-exon repeat is used for one purpose compared with another, indistinguishable repeat. Nevertheless, together with published observations regarding the abundance of transcripts containing mini-exon-derived sequences and the inability to detect linkage between a mini-exon sequence and the VSG coding exon, the identification of a short, discrete medRNA strongly supports a model of discontinuous transcription. In this model, the mini-exon-derived leader segment of VSG mRNAs is transcribed as a discrete product of the mini-exon repeats and, by one of several possible mechanisms, is ultimately found attached to the 5′-end of the VSG precursor RNA. The chimaeric intervening sequence is then removed by splicing, bringing together the 35-nucleotide leader with the coding portion to give the final mRNA of ~1.7 kb.

There are two general schemes by which this can most easily be imagined to occur. The first model, presented in Fig. 7*a*, predicts that RNA polymerase transcribes the medRNA and then dissociates from the mini-exon repeat, possibly as a medRNA/polymerase complex; transcription then reinitiates just upstream of the ELC using medRNA as a primer. The second model (Fig. 7*b*) proposed that medRNA and the coding-region RNA are independently produced as discrete transcripts and then post-transcriptionally ligated to each other. In both cases, splicing ultimately removes the intervening sequence to generate the mature mRNA.

The critical difference between the two alternatives is that post-transcriptional ligation requires a functional promoter (in the sense of a site for *de novo* initiation of transcription) upstream of the ELC whereas the reinitiation model proposes a site in this same position where RNA polymerase could only act in the presence of a primer (that is, medRNA). We are now attempting to test for this distinction *in vitro*.

We have previously reported the sequence upstream of an expressed copy of a VSG gene and compared it with a silent copy of that gene[19]. We found that the upstream region of the expressed copy consisted of multiple tandem repeats of ~76 bp flanking an unusual sequence of $(TAA)_{90}$. Although three 76-bp repeats are found upstream of the silent copy, $(TAA)_{90}$ is unique to the expressed copy of this gene and is, therefore, a candidate for the (re)initiation site upstream of expressed VSG genes. If this sequence is unique and mobile, it could be the basis for the mutual exclusion observed between the different expression sites. Equally, another, as yet undetected, mobile control element might have this role.

A critical question raised by the results reported here is whether discontinuous transcription involving a small RNA is a unique property of *T. brucei*. Is it, for example, a special adaptation which has co-evolved with antigenic variation? This is argued against by the finding that the same or similar mini-exon sequences are found in many RNAs (of unknown coding function), not only from bloodstream-forms of the parasite, but also from the procyclic insect forms where VSG genes are not

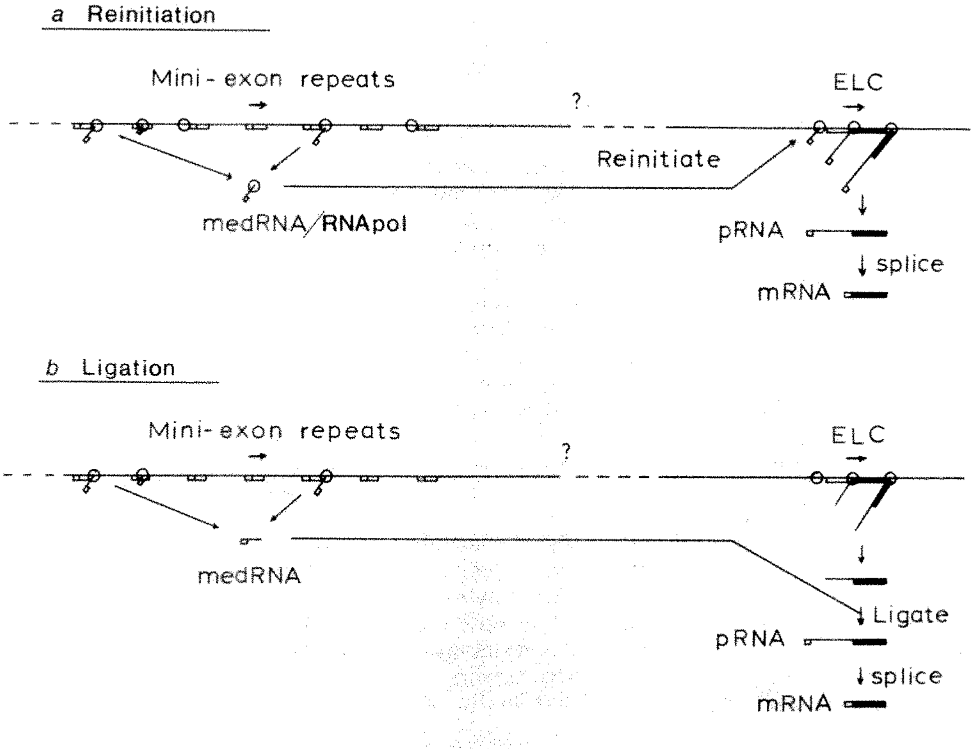

Fig. 7 Two models for discontinuous transcription of VSG mRNAs. *a*, The reinitiation model; *b*, the ligation model. The figure illustrates schematically the important features of the two models which are described in the text. The region of the mini-exon repeat which codes for the medRNA is represented by an open segmented box, the left half indicating the mini-exon coding for the 35-nucleotide spliced leader. The ELC region is also represented as a segmented box with the protein-coding exon shaded. The exon-derived portions of the precursor RNA (pRNA) are boxed in the same way. Uncertainty about whether the mini-exon repeats are linked to the ELC and if so over what distance, is indicated by a question mark over the dashed region. RNA polymerase is represented by an open circle.

expressed (ref. 21 and M. Parsons *et al.*, personal communication). In addition, the mini-exon sequence (or a conserved homologue) has been shown to be present in the genomes of several related species and genera which lack antigenic variation of the type observed for *T. brucei*[22].

Could discontinuous transcription be operating in these other cases? This question cannot, as yet, be answered, but some precedent does exist in systems which are otherwise totally unrelated. Transcription of the influenza virus is known to require a 5′-capped primer (10–15 nucleotides long) derived from cleavage of host mRNAs[36,37]. Coronavirus transcripts, on the other hand, are known to have a common 5′-leader sequence which is seemingly not joined to the coding portion of the RNA by conventional splicing, again strongly suggesting discontinuous transcription[38,39]. The fact that, in both these cases, transcription occurs by an RNA-dependent viral transcriptase may be an important distinction but they do provide a mechanistic precedent for discontinuity in primary transcripts. The observation made in Fig. 6 that a snRNA of yeast has substantial homology with the region known to be a donor splice site in medRNA, suggests that this snRNA (of unknown function) might be similarly involved in discontinuous transcription, albeit on a lesser scale (snR3 is nonessential; ref. 32). Such activity could further provide a molecular basis for the long-standing observation that heterogeneous nuclear RNAs often possess sequences at their 5′-ends which are derived from middle repetitive DNA[40–42] and that such sequences might be important in the control of developmentally regulated gene expression. The testing of this interesting hypothesis in trypanosomes may now be possible.

We thank Mr M. van Bree for technical assistance; Drs N. Agabian, P. Borst, G. Cross, J. Donelson, M. Lai, K. Stuart and their colleagues for exchange of information before publication; Dr M. Fedor for producing the synthetic oligonucleotide; and Ms M. A. Siri for secretarial help. This work was supported in part by a grant from the American Cancer Society (ACS IN 32).

On the origin of Triton and Pluto

William B. McKinnon

Department of Earth and Planetary Sciences, and McDonnell
Center for the Space Sciences, Washington University, Saint Louis,
Missouri 63130, USA

Lyttleton hypothesized long ago that Triton and Pluto originated as adjacent prograde satellites of Neptune[1]. With the presently accepted masses of Triton and Pluto–Charon[2,3], however, the momentum and energy exchange that would be required to set Triton on a retrograde trajectory is impossible. The mass of Triton has probably been seriously overestimated[4,5], but not by enough to relax this restriction. It is implausible that the present angular momentum state of Pluto–Charon has been significantly influenced by Neptune[6]. It could not acquire such angular momentum during an ejection event unless a physical collision was involved, which is quite unlikely. The simplest hypothesis is that Triton and Pluto are independent representatives of large outer Solar System planetesimals. Triton is simply captured, with potentially spectacular consequences that include runaway melting of interior ices and release to the surface of clathrated CH_4, CO and N_2 (ref. 7). Condensed remnants of this proto-atmosphere could account for features in Triton's unique spectrum[8–11].

The dynamics of Triton's orbital evolution are considerably simplified by the fact that its specific dissipation function, Q, at tidal frequencies, is much less than that of Neptune ($Q_T \ll Q_N$). Here I assume a standard solid-body Q for Triton of ~100 (ref. 12). A lower bound on Q_N can be derived by requiring that the outward orbital evolution of a satellite given by

$$\frac{\mathrm{d}a_s}{\mathrm{d}t} = 3k_{2N}\sqrt{\frac{G}{m_N}}\frac{R_s^5 m_s}{Q_N a_s^{11/2}} \tag{1}$$

is not so rapid that the satellite originated at the corotation radius of Neptune 4,500 Myr ago[12] (where m_s and a_s are the satellite's mass and semimajor axis; m_N, R_N and k_{2N} are Neptune's mass, radius, and tidal-effective potential Love number of the second degree; and G is the gravitational constant). k_{2N} is estimated at 0.43, subject to uncertainties in Neptune's rotation rate and J_2 (the coefficient of the second harmonic of the gravitational potential) (see ref. 13); other parameter values are given in Table 1. If Neptune's third satellite[14] is confirmed and proves to be regular and non-commensurate, then $Q_N \gtrsim 10^4$. A lower bound on the Q of Uranus of $\sim 2\times 10^4$ is set using Miranda[15] and a k_2 for Uranus of 0.28. The Qs of both planets should be comparable, and are probably much larger.

Accordingly, the monthly radial tide raised on Triton by Neptune dominates Triton's orbital evolution, except for orbits of very small eccentricity. This tide does not transfer angular momentum for a synchronously-rotating Triton, but in the cases of interest here, such non-synchronous spin angular momentum would be negligible compared with orbital angular momentum. The present fractional rate of change in Triton's orbital angular momentum, due to the tide raised on Neptune by Triton, is

$(\mathrm{d}a_T/\mathrm{d}t)2a_T$, where a_T is Triton's semimajor axis. Using equation (1), the total change over the age of the Solar System is a few per cent for $Q_N \sim 10^5$. Changes in inclination are similarly small.

Lyttleton's hypothesis is evaluated as follows: Triton and Pluto originate as regular direct satellites of Neptune, in circular orbits; orbital evolution brings them into a range of significant gravitational interaction, say, within the sphere of influence of the more massive satellite (the radius of which is given by $s \simeq a_>(m_>/m_N)^{2/5}$ (ref. 16), where $a_>$ and $m_>$ are the semimajor axis and mass of the more massive satellite), and Triton is sent into a retrograde orbit, potentially elliptical, with the same angular momentum as it has today. Conservation of angular momentum requires that the angular momentum of Pluto, l_P, increases to

$$l_P = (Gm_N)^{1/2}\{(\alpha m_T\sqrt{a_T} + m_T\sqrt{a} + m_P\sqrt{a})^2 + \beta^2 m_T^2 a_T\}^{1/2} \quad (2)$$

where m_T and m_P are the masses of Triton and Pluto–Charon, α and β are cos(21.5) and sin(21.5)—accounting for Triton's inclination of 158.5° (ref. 17), and a is the semimajor axis of the interaction. Pluto's post-encounter orbital energy is minimized for velocities perpendicular to its radius vector. The semimajor axis (elliptic or hyperbolic) of the new orbit, with respect to Neptune, is then:

$$a_P = |(l_P^2/Gm_N m_P^2 a) - 2|^{-1} a \quad (3)$$

If $l_P > (2Gm_N a)^{1/2} m_P$, the orbit will be hyperbolic. This is guaranteed for $m_T > (\sqrt{2} - 1)m_P$.

The relationship (3) is illustrated in Fig. 1 for a range of plausible mass ratios m_T/m_P. All the a_P shown correspond to hyperbolic trajectories. Orbits with $a_P < 1.62\ R_N$, however, are so energetic that once Pluto leaves Neptune's sphere of influence, it is not bound to the Solar System. Only for $a_P >$ 54.9 R_N is Pluto definitely bound. The accepted mass of Triton, $1.32\ 0.23 \times 10^{26}$ g, is due to Alden[2]. The combined mass of Pluto and Charon is known more precisely (±5%) (ref. 3) and suggests $m_T/m_P \sim 10$. In this case, momentum conservation alone determines that a Lyttleton-type interaction is not possible, unless the interaction takes place well outside the domain of regular satellites. This domain, $a \leq 60\ R_N$, is defined in analogy with the regular satellite systems of Jupiter, Saturn and Uranus. The outermost regular satellite in each system, Callisto, Iapetus and Oberon, orbits at 27, 59 and 23 units of its respective planetary radius.

Recent radiometric measurements[4,18,19] call Triton's mass estimate into question. Lebofsky's 2σ detection, in particular, yields a radius of 1,750±250 km (ref. 19). In lieu of accepting Triton as a heavy metal satellite, I assume a density appropriate to an ice–rock body of this size (~1.6 cm^{-3}) (ref. 20)—implying that $m_T/m_P \sim 3$. This lower mass ratio, however, does not make Lyttleton's hypothesis more physically acceptable. Note that neither the effect of a non-unity emissivity nor a surrounding atmosphere has been included in the radiometric modelling, and these would have competing effects on the derived radius. A better determination of Triton's mass is needed.

These arguments can be generalized to allow multiple encounters if the conservation of energy is accounted for. The encounters are assumed to be conservative, with the only restriction on Triton's final energy, $-Gm_N m_T/2\tilde{a}_T$, where $\tilde{a}_T$ is Triton's final semimajor axis, being that it exceed Triton's present value. The horizontal curves in Fig. 2 are Pluto's final semilatus rectum, $p_P = l_P^2/Gm_N m_P^2 = a_P|1 - e_P^2|$, where e_P is uto's final eccentricity, for various m_T/m_P. The vertical curves are Pluto's final semimajor axis, given by

$$a_P = a\left\{\frac{m_T}{m_P}\left(\frac{a}{\tilde{a}_T} - 1\right) - 1\right\}^{-1} \quad (4)$$

for $m_T/m_P = 10$ and two representative values of $\tilde{a}_T$. Ascending asymptotes (with increasing a) correspond to bound orbits. For ellipses, however, $p < a$, so only those $a_P \geq p_P$ correspond to possible orbits. In addition, the pericentre distance, $p_P/(1 + e_P)$, has a minimum of $p_P/2$ for $e_P = 1$, and Triton's apocentre distance has a maximum of $\sim 2\tilde{a}_T$. Thus even for $m_T/m_P = 1$, no bound orbits are possible because the final orbits of Triton and Pluto must be ~intersecting ones. A descending branch of a_P, for a given $\tilde{a}_T$, is the locus of unbound states (with respect to Neptune). The top part of the descending branch ($a_P \geq p_P$) corresponds to eccentricities of between $\sqrt{2}$ and 1; hence these orbits are also non-intersecting and are ruled out. The bottom of the descending branch corresponds to hyperbolic orbits with $e_P > \sqrt{2}$; hence, for large enough e_P, a pericentre distance small enough to allow intersecting orbits may appear feasible. The situation is very restricted, however, as a_P has a horizontal asymptote at $\tilde{a}_T m_P/m_T$. This limits e_P to $\{p_P/a_P + 1\}^{1/2}$. Pluto's final pericentre distance remains $> 2\tilde{a}_T$ for $m_T/m_P \geq 1$, regardless of the choice of $\tilde{a}_T$ or initial a. Thus, for plausible mass ratios, and under the stipulated initial conditions, a combination of orbital interactions to reverse Triton's motion cannot be found.

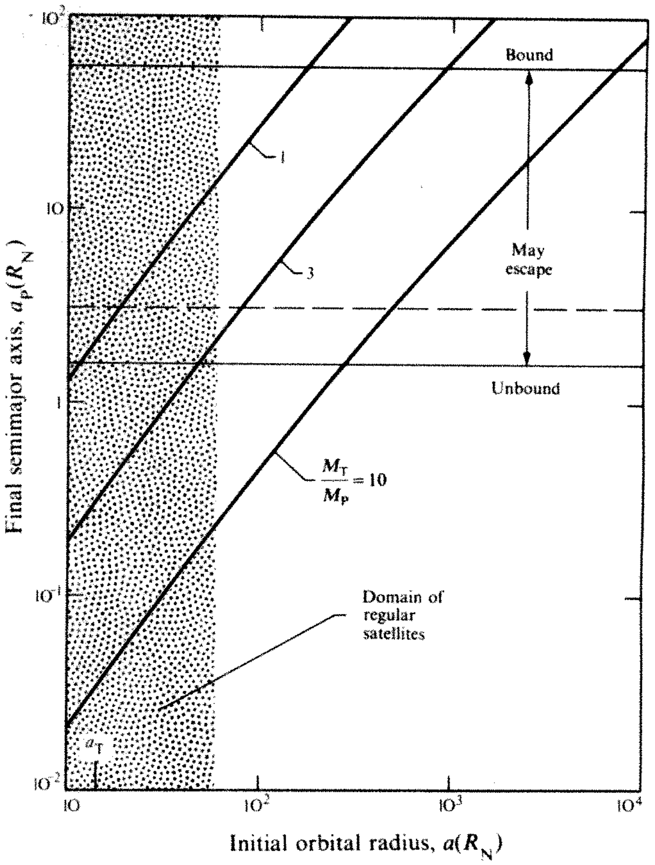

Fig. 1 Hyperbolic semimajor axis of Pluto, with respect to Neptune and after an interaction with Triton, as a function of initial orbital radius for three different mass ratios. These results, derived from angular momentum conservation alone, represent maximum values. Asymptotic velocities from Neptune of 2.25 and 13.1 km s^{-1} ($a_P = 54.9$ and 1.62 R_N) correspond to limits on bound or unbound solar trajectories, if Neptune's orbital velocity is taken into account. The dashed horizontal line is the minimum a_P for ejection into a direct, bound solar orbit. For plausible mass ratios, any interaction to reverse Triton's orbital motion and retain Pluto in the Solar System must take place well outside the domain of regular satellites (see text).

This conclusion, more severe than that due to momentum conservation alone, is not changed by considering tidal interaction with Neptune during the encounters. In addition, allowing the initial conditions to be set when the difference between the semimajor axes of the two 'satellites' closes to within the radius of either the sphere of influence, s, or an even wider sphere of perturbation, can bring Triton and Pluto's final orbits closer together (if Triton is the innermost of the pair), but not

Table 1 Parameter values

Object	Quantity	Value	Reference
Neptune	m_N	1.03×10^{26} kg	36
	R_N	24.75×10^3 km; 1 bar, equatorial	37
	J_2	4.3×10^{-3}	17
	Rotation period	~15 h; dynamical	38
Uranus	Mass	8.67×10^{25} kg	36
	Radius	25.5×10^3 km; 1 bar, equatorial	39, 40
	J_2	3.35×10^{-3}	40
	Rotation period	15.5 h; dynamical	40
Triton	a_T	354.3×10^3 km	17
Pluto	R_P	~1,500 km	41
	Q_P	~100	Assumed
	k_{2P}	$\sim 2.7 \times 10^{-2}$	Based on unity cgs density and water-ice rigidity

sufficiently to have them interacting for $m_T/m_P \geq 1$. Of course, for $m_T \ll m_P$, Triton can be sent retrograde, but Pluto will remain direct.

The present angular momentum state of the Pluto–Charon system (that is, that contained in their mutual orbits and spins) is not consistent with a Neptune satellite origin either. If Pluto–Charon ever orbited Neptune with a semimajor axis a, tides raised on Pluto by Neptune would extract angular momentum from the system at a rate

$$\frac{\mathrm{d}H}{\mathrm{d}t} = \frac{3}{2} \frac{G k_{2P} m_N^2 R_P^2}{a^6 Q_P} \tag{5}$$

where H is the angular momentum, and R_P, Q_P and k_{2P} are, respectively, Pluto's radius, specific dissipation function and potential Love number (see Table 1). The present angular momentum of Pluto–Charon is uncertain due to the difficulty in estimating Charon's mass, but probably lies between 2.4 and 6.6×10^{37} g cm^2 s^{-1}. Extraction of angular momentum would cause the Pluto–Charon system to contract and eventually coalesce. The coalesced object would then be spun down to synchronous rotation[6]. The time scale for 'fusion' and spin-down is

$$\tau = H \bigg/ \left(\frac{\mathrm{d}H}{\mathrm{d}t}\right) \sim 1 \times 10^5 \left(\frac{a}{a_T}\right)^6 \text{ yr} \tag{6}$$

Thus collapse of the Pluto–Charon system and spin-down would occur rapidly unless Pluto–Charon orbited Neptune at a great distance ($\tau \gtrsim 100$ Myr for $a > 45 R_N$). These same arguments apply if the original state of Pluto–Charon was a coalesced, rapidly-rotating proto-Pluto (the angular momentum limits above correspond to primordial rotation periods between ~7 and 11 h; see refs 21, 22).

Only a physical collision could impart the requisite angular momentum to Pluto–Charon prior to its ejection from the Neptune system. A close pass to Pluto by a more massive object could exert an extremely large torque on Pluto but the time scale for the interaction would be severely limited. A grazing pass by an object with even the mass of the Earth would be restricted to last a few 10^3 s, and the angular momentum imparted, according to equation (5), would be only a few per cent of the present total. A larger transfer of angular momentum may be possible for the slowest encounters with a massive grazer, if tidally-induced fission[23] occurs, but the restriction of slow encounters again requires Pluto to initially be in a distant orbit about Neptune.

With regard to ejection dynamics, the reduction of the interaction cross-section from a gravitational one to approximately one of collision makes 'rogue' planet hypotheses such as that of Harrington and Van Flandern[24] probabilistically untenable. Farinella *et al.* call on a captured Triton to eject Pluto as its capture orbit decays[25], but this hypothesis still requires a physical collision with Pluto, following which, gravitationally-bound plutonian debris accretes into a binary and eventually reaches stable, resonant[26] solar orbit; the last requires an additional mechanism. This is an unlikely series of events.

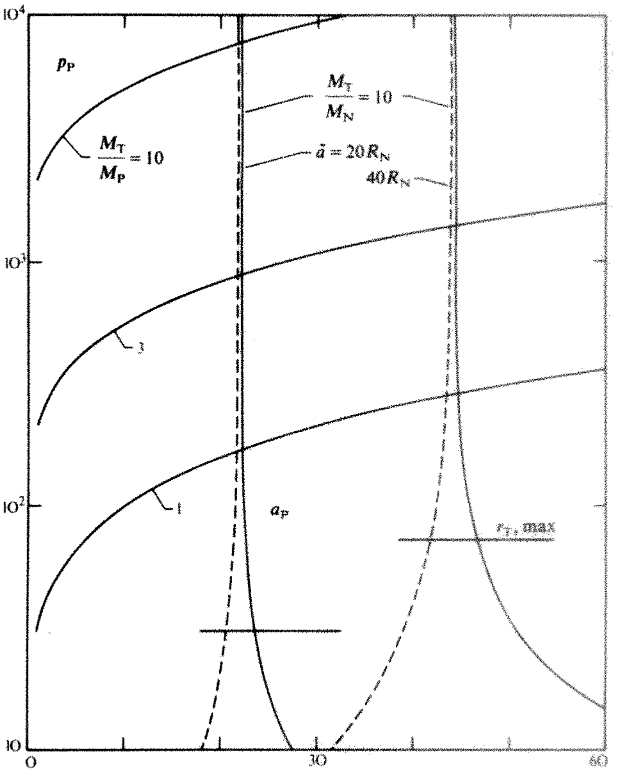

Fig. 2 Semilatus rectum and semimajor axis of Pluto, with respect to Neptune and after interactions with Triton, as a function of initial orbital radius for various mass ratios and final Triton semimajor axes. Only the solid part of the asymptotes represent possible orbits, but none have pericentre distances that approach Triton's final apocentre distance (short horizontal lines). Hence, for mass ratios greater than one, a series of interactions that reverses Triton's orbital motion and that conserve angular momentum and orbital energy cannot be found.

The preceding arguments effectively decouple the origin of Pluto from that of any Neptune satellite. Hence, for Triton to begin as a direct satellite and end up retrograde would require interaction with an unknown and *ad hoc* object. I propose a simple reversal of Lyttleton's hypothesis: instead of beginning as satellites of Neptune, Triton and Pluto originate as satellites of the Sun. The existence of large, outer Solar System planetesimals is consistent with the dynamics of planetary accretion and may even be necessary to explain planetary eccentricities, inclinations, and obliquities (see ref. 27). Pluto–Charon's binary status could be related to hypotheses regarding binary asteroid formation,[21,28–30] and Triton's capture could be effected by the combination of a retrograde, temporary orbit about Neptune[31] and a dissipative mechanism such as gas drag[32,33].

If Triton had been captured, then it should have experienced a spectacular thermal event. As $Q_N \gg Q_T$, nearly all of the orbital energy dissipated during post-capture orbital evolution is deposited in the body of Triton. Gas drag, while potentially important for capture, did not result in a major change in orbital elements, as the evolution of Triton's inclination has been moderate[32]. Calculations[7] show that collapse of an elliptical post-capture orbit, extending to the edge of Neptune's sphere of influence (~3,500 R_N), to one where the semimajor axis is within a few per cent of the present value, requires ~4 Q_T Myr, for a constant Q_T. Most of the energy (~80%), however, is dissipated in an ~1.5 Q_T Myr period near the end. The equivalent surface heat flow, for reasonable Q_T, is far too great for solid-state convection in ice to transport, so it is extremely probable that the icy component of Triton completely melted during the latter phase of capture. Q_T itself would plummet as melting began, accelerating differentiation.

Catastrophic melting of Triton's ices should have released its inventory of clathrated gases to the surface, which for accretion outside a circumplanetary nebula would be CH_4, CO, and N_2 (refs 34, 35). A condensed fraction of this primordial atmosphere may be responsible for Triton's unique surface composition—present spectral identifications include liquid nitrogen[11] and methane ice[9-11].

X-ray haloes around supernova remnants

G. E. Morfill*, L. O'C Drury† & B. Aschenbach*

Recent observations of the Cas-A supernova remnant have shown X-ray emissions not only from the interior, but also from a fainter 'halo' extending beyond what is normally regarded as the outer boundary, or shock front[1]. We suggest here that this may be due to the diffusion of energetic, charged particles out of the remnant giving rise to precursor structure of the type predicted by the theory of diffusive shock acceleration. If this is the case we are seeing thermal emission from ambient gas heated by compression and wave dissipation.

The radio synchrotron emission from supernova remnants is clear evidence that they contain relativistic electrons; it is widely believed that they are also the major source for the galactic cosmic-ray nucleon component, but so far there has been no direct observational evidence for this. Cosmic-ray nuclei have an energy density which exceeds that of the electrons by about two orders of magnitude; for supernova remnants to be responsible for their origin, this implies that a substantial part of the remnant energy must reside in energetic charged particles[2]. This raises the question of how these particles are accelerated. Interstellar plasmas are typically so tenuous that cosmic rays are scattered only by the irregular structure of the magnetic field. Because the field lines are effectively frozen into the background plasma these irregularities can move relative to the bulk fluid at maximum speeds of the order of the magnetosonic speed. As Fermi[3] recognized, this is a rather unusual physical system in that macroscopic degrees of freedom, the magnetic fluctuations and their associated plasma, couple to a few individual particles. If the fluctuations are excited randomly this leads to a diffusion of the particles in momentum space which is the standard second-order Fermi acceleration mechanism. This is normally slow; however, at a shock front where the bulk plasma together with its embedded magnetic structures is suddenly decelerated (in the shock frame) the scatterers, instead of moving randomly, converge, giving rise to a much faster first-order acceleration[4-8]. Perhaps the major attraction of this process, usually called diffusive shock acceleration[9-11], is that an elementary analysis in which the reaction of the particles is neglected, predicts that the accelerated particles should have power-law spectra in momentum with exponents close to those inferred for the sources of the galactic cosmic rays.

It is, however, clear that the reaction of the particles on the scattering irregularities, and through these on the bulk plasma flow, cannot be ignored if the energy density of the particles is significant, as is thought to be the case in supernova remnants[5,12]. The particles diffuse ahead of the shock into the upstream region and produce an adverse pressure gradient which decelerates the flow into the shock. This gradient also works on the scatterers at the rate $-v \cdot \mathrm{grad}\, P_c$, where v is the velocity of the scatterers and P_c is the energetic particle pressure; clearly, and as one would intuitively expect, those fluctuation modes which move upstream relative to the plasma are amplified and those which move downstream are damped. The energy transferred to the amplified modes can be estimated to be of the order of the Alfvén Mach number of the shock times the background magnetic field energy[9,13]. For strong astrophysical shocks, Alfvén Mach numbers of 20 or greater are expected. Thus in the absence of any dissipation, or radical change in the nature of the modes, the energy content of the fluctuations would become many times that of the background field; it seems doubtful that so much energy could be stored without various instabilities setting in which transfer excess energy to the plasma and keep the fluctuation amplitude of the order of unity.

Although the details of this process are very complicated, its main features have been described by a simple model[13-15] in which only the energy and momentum fluxes associated with the thermal particles (treated as an ideal non-relativistic gas), the energetic particles (treated as an ideal relativistic gas) and the magnetic fluctuations (taken to be damped backwards-travelling Alfvén waves) are considered, while the shock structure is taken to be plane and steady.

We have calculated the shock structure and the Bremsstrahlung emissivity predicted by this model. Figure 1 shows an example of a shock with Alfvénic Mach number 20 and equal thermal particle, energetic particle and magnetic pressures far upstream. This high Mach number should be characteristic of young supernova remnant shocks. As can be seen, the shock

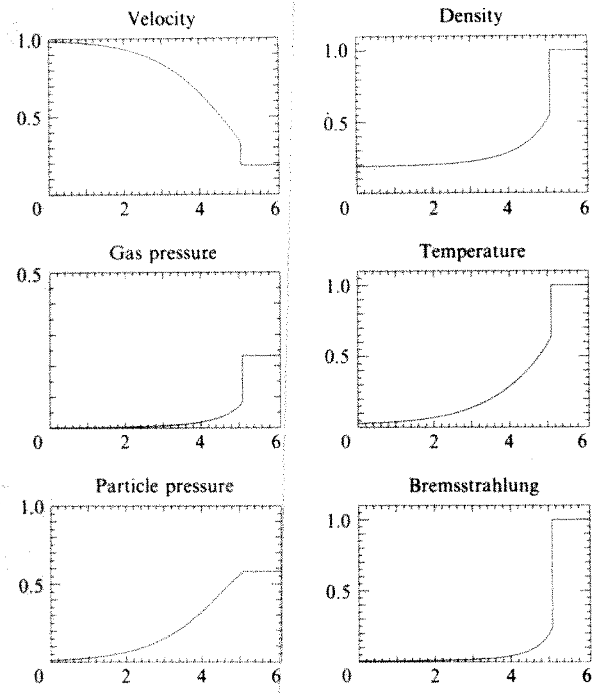

Fig. 1 Effects of cosmic rays on parallel magneto-hydrodynamic shocks. The values of the gas-velocity, gas-pressure and cosmic-ray pressure are normalized such that the total mass and momentum fluxes are unity. All pressures are equal far upstream, and the Alfvén Mach number is 20. The values of the gas-density, gas-temperature and, as a Bremsstrahlung-emissivity measure, $(\text{density})^2 \times \sqrt{\text{temperature}}$ are normalized to the post-shock region. The horizontal axis gives the length scale in units of diffusion coefficient/shock velocity.

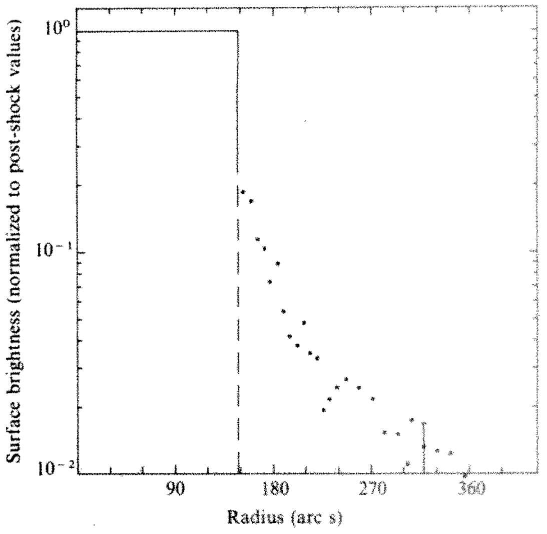

Fig. 2 Surface brightness of the Cas-A 'halo' plotted as a function of distance from the shock. The 'halo' emission is the excess derived by Stewart *et al.*[1]; the data have been normalized to the remnant brightness of the outer ring, and the detailed internal structure of the remnant has not been considered.

acceleration of cosmic rays (predominantly nuclei) is rather important. The cosmic-ray pressure, in the steady model, is about twice the thermal gas pressure and about twice the kinetic energy density. Also, the gas density and velocity profiles are modified ahead of the shock, and the gas is pre-heated by the Alfvén wave decay and the compression in front of the shock. The 'precursor' length scale is rather uncertain because it depends on the (poorly known) diffusion coefficient κ of the particles; however, if they are accelerated at the shock then $\kappa \lesssim R\dot{R}$, where R is the shock radius. The 'precursor' length scale is then less than, or comparable to, the shock radius. The point of interest is that wave dissipation and compression together heat the gas in the precursor to temperatures which are not much lower than those behind the shock.

This implies that the processes described above give rise to extended thermal X-ray (Bremsstrahlung and line) and possibly coronal line (for example, [Fe XIV] 5,303 Å and [Fe X] 6,374 Å) emission outside the shock radius of a young supernova remnant. From an observational point of view this extended halo might be difficult to detect because of its low surface brightness (see Fig. 1). Only Cas-A is definitely known to possess an extended halo, from the Einstein Observatory measurements. Several physical processes for this phenomenon have been discussed, such as, electron 'leakage' ahead of the shock, shock heating by ejecta fragments and scattering by interstellar dust[1]. We present here an alternative interpretation, which could be checked, for instance, by a search for haloes around point sources, and other supernova remnants.

Figure 2 shows the radial variation of the X-ray excess surface brightness outside the shock, in the case of Cas-A. The excess emission outside the shock was normalized to the emission just behind the shock, which, ignoring the complicated internal remnant structure, is simply represented as a constant level. A halo length scale of ~50 arc s is indicated, roughly one-third of the remnant radius. This is in agreement with the upper bound determined from the theory, and, therefore, we tentatively suggest that the faint 'haloes' may be produced by the processes described above. This being the case, we are seeing evidence for a dynamic role of cosmic rays in the interstellar medium, and for the acceleration of nuclei in supernova remnants. A comparison with radio observations of the synchrotron emission may then allow a determination of the relative intensities of the nucleonic and electronic components. If confirmed by further observations, this will have important consequences for the evolution of supernova remnants[16] and the structure of the interstellar medium. Although the model calculations shown in Fig. 1 are based on diffusive shock acceleration at the outer boundary of the remnant, a similar situation will be produced by an efficient acceleration mechanism inside the remnant, provided that the accelerated particles diffuse out (ref. 1 and H. J. Völk, personal communication). In the case of Cas-A, diffusive acceleration at the outer shock seems to work well; however, in view of the complicated and violent internal structure and abnormally high radio luminosity of Cas-A this may not be the only source of cosmic-ray acceleration. To test our interpretation of the X-ray data, and the implied consequences for the interstellar medium, observations in other spectral regions and very deep X-ray exposures are needed.

Spectral feature of 31 December 1981 γ-ray burst not confirmed

P. L. Nolan*‡, G. H. Share*, E. L. Chupp†, D. J. Forrest† & S. M. Matz†

* E. O. Hulburt Center for Space Research, Naval Research Laboratory, Washington DC 20375, USA
† Department of Physics, University of New Hampshire, Durham, New Hampshire 03824, USA

The emission lines reported at 400–500 keV in the spectra of γ-ray bursts[1] have been interpreted as redshifted positron annihilation lines, and, together with the lower-energy cyclotron lines[1], are the most direct evidence that bursts occur on the surface of neutron stars[2]. Therefore, it is important to confirm the existence and determine the properties of these features. So far, the most significant detections of emission features have been reported from the Konus experiments on Veneras 11–14. Possible confirmatory observations have suffered from limited statistical significance or difficulties in interpretation. Here we compare measurements of a γ-ray burst at 01:37 UT on 31 December 1981, using the Solar Maximum Mission (SMM) γ-ray spectrometer with those made by the Konus instruments. The SMM spectra exhibit no evidence for the presence of emission features reported by the Konus group[3].

Annihilation lines have been reported in ~5% of the bursts observed by the Konus instruments from 1978 to 1982[1,3]. The typical emission features observed by Konus are centred at 400–450 keV and have widths of ~200 keV (FWHM). The strong feature in the 5 March 1979 burst[2] fits this description; however, that event is so unusual that we are reluctant to include it in the same class as other bursts[4]. There are two other Konus line detections for which simultaneous observations were made with other spectrometers. These bursts occurred on 4 and 19 November 1978. The 4 November line had a width ~200 keV, which is typical of the Konus detections, while the 19 November feature was very broad. Barat[5] confirms the presence of both of these lines. Teegarden and Cline[6] also reported a narrow line at ~420 keV in the spectrum of the 19 November burst, using data from the ISEE 3 germanium spectrometer, but the statistical significance was marginal at best. They found no evidence for a line in the 4 November burst. Fenimore *et al.*[7] analysed the 4 November burst using the scintillation spectrometer on ISEE 3; they found that the apparent strength of the ~400-keV line was strongly dependent on the choice of continuum model, and could be consistent with zero. They also found no evidence for a line in the 19 November burst.

The present observation was made using the Gamma-Ray Spectrometer[8] (GRS) on the SMM spacecraft. The GRS main detector consists of seven NaI scintillators viewing about half of the sky, centred on the Sun. It covers the energy range 0.3–9 MeV with a resolution of 7% FWHM at 0.662 MeV. The gains of the seven crystals are continuously stabilized by ^{60}Co calibration sources. For a burst in the centre of the field-of-view, the effective area is 4–6 times larger than that provided by the Konus system at 0.5 MeV. The time resolution for spectroscopy is 16.384 s. We analyse spectra using a detector response function based on calibrations made before and during flight and on a Monte Carlo computer simulation. The line profiles predicted by this response function have been verified in flight by observation of lines from solar flares and the Earth's atmosphere, including the annihilation line at 0.511 MeV (refs 9, 10).

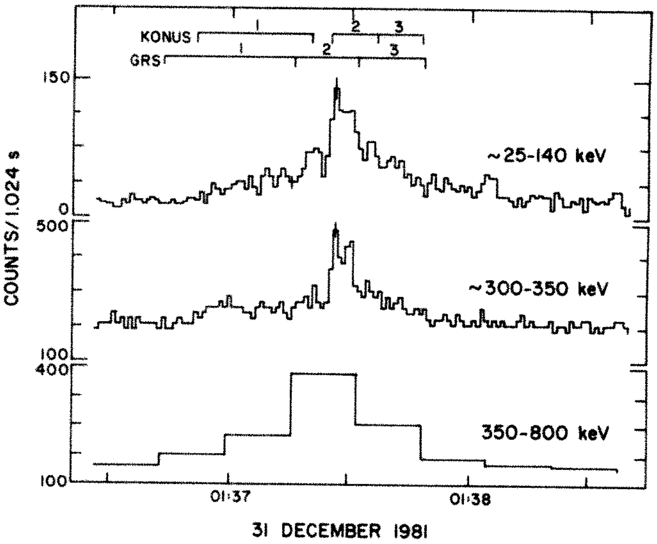

Fig. 1 Time profile of the burst in three GRS energy bands. The top shows the time intervals for which spectra are available from the GRS and Konus instruments.

Figure 1 shows the time profile of the burst, as observed by the GRS auxiliary X-ray detector and main detector. The time resolution for spectroscopic observations is illustrated by the 0.35–0.8 MeV profile. This was an unusually long burst (about 2 min) with several brief subbursts. The time delay between the GRS and Konus detections (about 53 s) was determined by matching the most prominent of these peaks. The report of the Konus observations[3] includes spectra of three time intervals; these are shown at the top of Fig. 1. Broad emission features extending to high energy were reported for intervals 2 and 3. Also shown are the corresponding intervals for which GRS spectra are available. Because the Konus intervals are long (12 s), a direct comparison is possible.

Based on preliminary data from other satellites and from analysis of the response of the GRS shield detectors, we estimate that the position of the burst is ~50° from the GRS viewing direction. This is well within the GRS field of view. As compared with the on-axis response function, the effective detector area at 50° is reduced by about 15% and a small energy-dependent correction is required because of partial screening by the shield and other parts of the instrument. The effect of this correction is to increase the inferred flux near 500 keV by ~5% with respect to higher and lower energies. Thus, applying this correction will enhance any emission features which may be present. The correctness of this procedure will be demonstrated below by the good agreement of the GRS and Konus results in interval 1.

The Konus and GRS spectra for the three intervals are plotted in Fig. 2. The GRS energy channels have been combined to match the Konus channels. For illustrative purposes, the normalizations of the Konus spectra have been adjusted to compensate for the slightly different accumulation intervals of the two instruments. To accomplish this, we compared the average counting rates in the GRS and Konus time intervals, using the 40–140 keV band of the GRS X-ray detectors (1.024 s time resolution). This adjustment is not used in the quantitative analysis described below. The agreement in absolute flux for the two instruments is good to about 30% in the overlapping energy range (0.3 to ~1 MeV). Of course, these power-law functions could not be extended to lower energy; the gradual curvature of the spectra below ~200 keV is evident in Fig. 2.

A single smooth function could fit the spectra from both instruments in interval 1, with a small shift in relative normalization. However, there is no evidence in the GRS spectra for the features which are found in the Konus spectra in intervals 2 and 3. Power-law spectra will fit the GRS data acceptably over the entire 0.3–0.9 MeV range in all three intervals. Of course, these power-law functions could not be extended to lower energy; the gradual curvature of the spectra below 200 keV is evident in Fig. 2.

---

‡ Present address: W. W. Hansen Laboratories, Stanford University, Stanford, California 94305, USA.

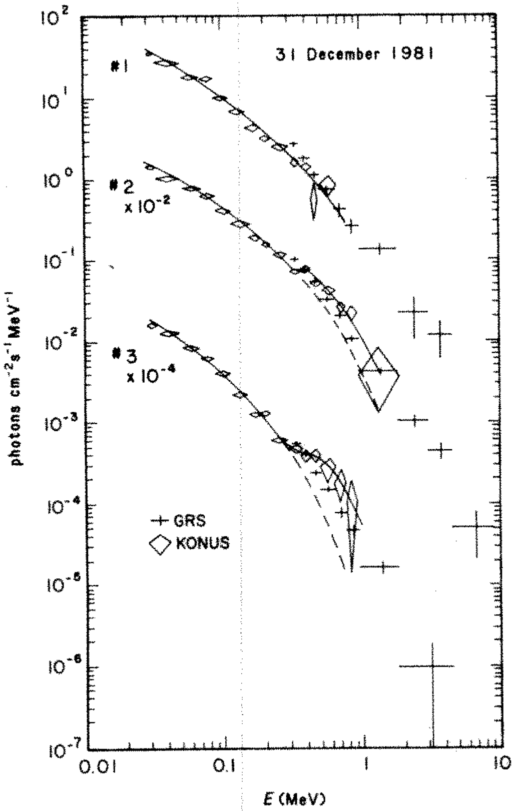

Fig. 2 Photon spectra for the three time intervals from Konus and GRS. The curves represent the models fit to the Konus data by Mazets *et al.*[3]. Solid line, thermal bremsstrahlung + emission feature; dashed line, high-energy extension of bremsstrahlung.

To make direct comparisons between the GRS data and the Konus model spectra, we multiplied the Konus models by the GRS detector response matrix and compared the results with the raw GRS data. We allowed the intensity of the model spectrum to be a free parameter (to account for possible errors in absolute calibration of the instruments), and adjusted it for the best agreement. The comparison was made only in the energy ranges for which both Konus and GRS data are available. In interval 1, the agreement was good: $\chi^2 = 4.3$ for 3 d.f. The best χ^2 values obtained for the other two intervals are unacceptable: 138 for 6 d.f. in interval 2, and 137 for 5 d.f. in interval 3. In both cases the model has a flattening in the 0.3–0.5 MeV range, which is not compatible with the GRS data. Figure 3 illustrates the results for interval 3. It shows, in terms of uncorrected detector counts, the GRS data and the Konus model (adjusted in intensity for the best agreement). The value of the upper limit that we can establish on the flux in a broad line depends on the continuum model chosen. Conservatively, our 99% confidence upper limit is 0.5 photons cm^{-2} s^{-1}, about one-quarter of our estimate of the strength of the Konus feature.

We repeated this analysis, omitting the lowest-energy GRS channel group (~300–350 keV). As we have no energy calibration below a 389 keV background line, it is possible that the assumed width of the lowest channel group could be in error. The agreement in interval 1 continued to be good. Even though the lowest channel group contained the greatest number of counts, the best χ^2 values in the other two intervals remained unacceptable: 44.5 for 5 d.f. in interval 2 and 59.4 for 4 d.f. in interval 3.

The intervals of the two instruments are not identical. However, it is unlikely that a rapid change in the spectrum could have produced the difference in the results. The last two Konus intervals are entirely contained within the combined GRS intervals 2 and 3. The remaining portion of GRS interval 2 is a time of lower burst flux, so its contribution is relatively small. The difference in the results from the two instruments is not subtle.

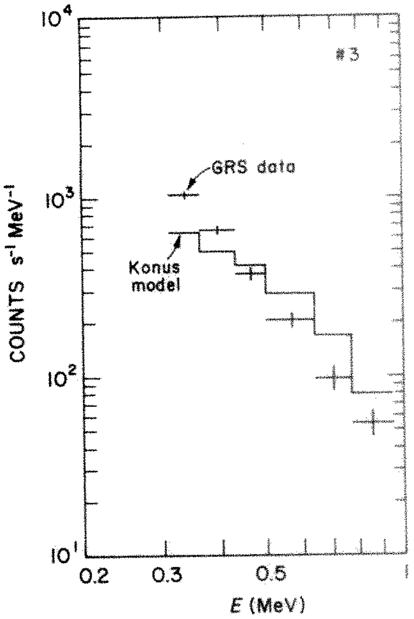

Fig. 3 GRS detector energy loss spectrum of the third interval. The histogram is the Konus model, multiplied by the GRS response matrix, with normalization adjusted for best fit.

There is a flattening of the spectrum in Konus intervals 2 and 3 which is not present in either of the corresponding GRS spectra. In the 0.3–0.5 MeV range, the GRS spectra are fit by power laws with indices of -2.00 ± 0.15 and -2.47 ± 0.23. The two Konus spectra are much flatter, with indices of > -1.2 in this energy range.

It is not certain that we can reconcile the results from the two experiments. As shown above, the continuum shapes are similar, but there are differences in narrow energy bands. We believe that they may be attributed to different data analysis procedures. The Konus data are presented only in the form of 'photon' spectral plots, corrected for the effects of the detector response. The process of producing such graphs is model-dependent, and in many cases, the plotted points tend to move to agree with the model[7]. We do not know to what degree the Konus spectra are prone to such 'compliance', which is due to non-diagonal components in the detector response matrix. The GRS should be less subject to compliance, because the detector is larger and has CsI anticoincidence shields to suppress the detection of Compton-scattered photons. (For example, the derived photon fluxes at 0.3 and 1 MeV vary by only about 20% for a range of input model spectra from $E^{-1.1}$ to E^{-4}.) If this effect is not enough to explain the differences, the only other explanation is a very unlikely fluctuation of the spectrum at just the right time. The best understanding of the nature of a spectrum can be obtained from statistical measures of its agreement with various models. However, the statistical significances of the reported features in the Konus data unfortunately are not given.

We have previously reported a weak (0.4 photon cm^{-2}, 2.5 σ detection) and relatively narrow feature near 475 keV in the first half of GRS interval 1, which contains about 5 s of the burst[11]. But this is not a significant detection, and it is much weaker than the features reported by Konus later in the burst. Indeed, it is about a factor of 4 weaker than the weakest lines detected by Konus in other bursts. Thus this possible feature can have little to do with the features discussed here. We know of only one other burst observed by GRS (28 March 1982) for which Konus spectra have been published. No annihilation lines were found in either the GRS or Konus spectra in that burst.

The GRS observations are inconsistent with the presence of the reported emission features in the burst of 31 December 1981. Because the existence of features such as these is one of the principal pieces of evidence that bursts occur on neutron stars, it is important to assess the significance of all the reported Konus line features.

We thank E. P. Mazets for discussions concerning the Konus observations. Our colleagues Erich Rieger and James Kurfess provided valuable assistance. P.L.N. was supported by a fellowship from the National Research Council. This work was supported by NASA contracts S-70926A at NRL and NAS S-23761 at UNH and by BFFT contract 010K 017-ZA/WS/WRK 0.275.4 at MPI.

The discovery that polyacetylene, $[CH]_x$ could be reversibly electrochemically oxidized or reduced ('doped')[1] has led to its usage as an electrode in light-weight rechargeable storage batteries[2,3]. Using a 100-μm thick electrode comprised of 20–30 nm diameter fibrils[4], performance characteristics slightly superior to those of the lead-acid battery have been achieved. Our cyclic voltammetry study utilizing ultrathin (<0.1 μm) films of $[CH]_x$ comprised of 2–3 nm microfibrils shows significantly improved electrode properties. A current density of 2.4 MA kg^{-1}, power density of 8 MW kg^{-1}, average potential of 3.5 V, maximum energy density of 250 W h kg^{-1} and coulombic efficiency >95% have been obtained with a Li/salt/$[CH]_x$ system. The potential of polyacetylene electrodes for light-weight rechargeable batteries is, therefore, several orders of magnitude higher than presently recognized.

Since the minimum detectable amount of $[CH]_x$ using cyclic voltammetry is ~100 pg, the 20–500 ng of $[CH]_x$ deposited on electron microscopy (EM) grids give excellent signal-to-noise ratios, and quantitative calculations involving doping level (y in mol/mol CH), energy density, efficiency, power density, and current density are possible. These thin films have proved to be ideal for carrying out rapid, numerous electrochemical experiments. The time taken for complete charging and discharging has been accelerated by more than three orders of magnitude. Morphological changes resulting from electrochemical treatment may then be examined directly by electron microscopy and electron diffraction. Because very low currents are involved in our battery experiments, resistive losses in the electrolyte and through the polymer film are negligible, allowing the examination of the limiting charging and discharging characteristics of $[CH]_x$ itself.

The method used to polymerize acetylene directly onto EM grids using a Ziegler–Natta catalyst has been described elsewhere[5–7]. A film of ~0.1 μm thickness was obtained, composed of a network of loosely-packed $[CH]_x$ fibrils of 2–3 nm diameter. Platinum wire contact was made to an EM grid and the grid immersed in 2 ml of 1 M $LiClO_4$ in dry propylene carbonate, 0.35 M $LiBF_4$ in propylene carbonate, or 0.5 M $LiClO_4$ in sulpholane in a dry box. Potential and current was controlled with a Princeton Applied Research (PAR) 173 potentiostat, and charge was recorded with a PAR 179 digital coulometer. Potential ramps for cyclic voltammetry were generated using a PAR 175 programmer and fast discharging transients were recorded on a Tektronix 564B storage oscilloscope.

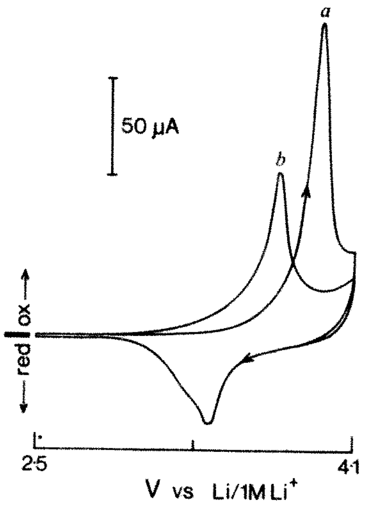

Fig. 1 Cyclic voltammetry of 300 ng $[CH]_x$ on an EM grid in 1 M $LiClO_4$ in propylene carbonate at a 50 mV s^{-1} scan rate: *a*, first scan; *b*, second and subsequent scans.

Cyclic voltammetry of *cis*-rich $[CH]_x$ on EM grids (Fig. 1) gives clear evidence of electrochemical isomerization to the *trans* polymer, a phenomenon that has been inferred from IR studies on electrochemically-doped $[CH]_x$ (ref. 8). The first scan (curve *a*) gives an oxidation peak at 3.96 ± 0.05 V versus $Li^0/1$ M Li^+. The second and all subsequent scans (curve *b*) give a reproducible peak at 3.74 ± 0.03 V. The fact that complete *cis–trans* isomerization occurs on one electrochemical cycle is confirmed by electron diffraction.

Extending the potential range of cyclic voltammetry shows a second, larger peak (Fig. 2*c*). This oxidation is not reversible and, in fact, extended oxidation of $[CH]_x$ leads to the degradation of the electronic properties of doped polyacetylene[9]. Experiments we have done on thicker, previously weighed films show that the stoichiometry of exhaustively oxidized polyacetylene is $[(CH(ClO_4)_{0.5}]_x$. Thus, we are provided with a direct electrochemical way of determining the total quantity of $[CH]_x$ on an EM grid.

The real potential of $[CH]_x$ as a battery material lies in very high power density and current density applications. Figure 3 shows the excellent discharge characteristic of $[CH(ClO_4)_{0.06}]_x$ film on an EM grid, discharged at an average power density of 8 MW kg^{-1} and a current density of 2.4 MA kg^{-1}. These values were obtained at a constant current of 1.0 mA. In the case of the standard thick $[CH]_x$, average power densities of up to 600 W kg^{-1} and current densities of ~20–200 A kg^{-1} have been reported. This large difference in battery performance parameter is due to the resistive potential losses in film and electrolyte, and limited access of counter ion to $[CH]_x$ fibrils. Also, the cyclic volatmmetric scan rates of 2 mV s^{-1} to 200 mV s^{-1} which correspond to charging times of 850 and 8.5 s, respectively, represent an increase of over 1,000-fold in charging rate over that used for thick films[2,3]. Even at these high charging rates, the $[CH]_x$ is doped to saturation, indicating that solid-state diffusion of counter ions into $[CH]_x$ microfibrils is not a limitation[10].

Although a maximum reversible dopant level of 6% was achieved by oxidation of the ~20 nm fibrils found in thick films[2,3], it was generally hoped that by varying the morphology of the polymer or the composition of the electrolyte, higher oxidation levels, and hence energy densities, could be obtained[3].

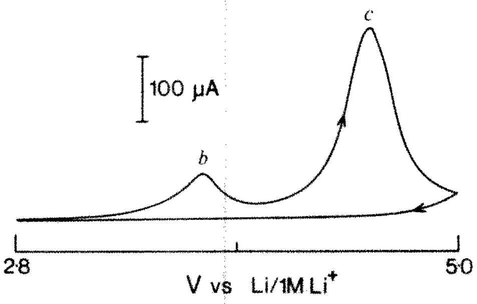

Fig. 2 The exhaustive oxidation of $[CH]_x$ on an EM grid at 50 mV s^{-1} scan rate.

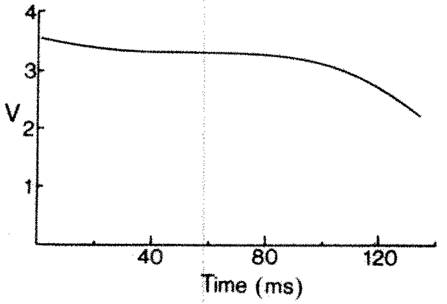

Fig. 3 Fast discharge of a $[CH(ClO_4)_{0.06}]_x$ sample on an EM grid at 2.4×10^6 A kg^{-1}.

For example, if the maximum dopant level were a surface-area related phenomenon, thinner $[CH]_x$ fibrils should lead to a higher energy density. We have found that the maximum reversible oxidation level for the ~3 nm fibril of $[CH]_x$ on EM grids is 6 ± 1% which is relatively insensitive to the counter ion. The average discharge voltage compared with $Li^0/1$ M Li^+ is 3.4 V giving an energy density of 280 Wh kg^{-1} which falls in the range of 176–340 Wh kg^{-1} found for thick films[3,11].

Cycling between 2.5 and 4.2 V, the potential at which $[CH]_x$ starts to degrade, gives coulombic efficiencies in excess of 95% when corrected for background (bare EM grid). This is compared with the 80–90% efficiency for the thick $[CH]_x$ electrodes. Note that the discharge of polyacetylene cannot be represented as the charging of a capacitor[12], as the constant current discharge characteristics of a capacitor would be linear and one would expect the energy density ('capacitance') to be proportional to the surface area of the $[CH]_x$ for ultrathin and thick $[CH]_x$ films.

This study establishes some of the limiting battery performance parameters for $[CH]_x$. Taking average current and power densities obtained with thick $[CH]_x$ films, one can seriously underestimate the true potential of $[CH]_x$. Realization of even fractional gains in these expected current and power densities could improve the technology of light-weight rechargeable batteries.

Thermoluminescence as a palaeothermometer

R. K. Guimon, K. S. Weeks, B. D. Keck
& D. W. G. Sears

Department of Chemistry, University of Arkansas, Fayetteville,
Arkansas 72701, USA

Chondritic meteorites are widely regarded as a unique source of information on the chemical and physical processes that occurred in the early Solar System. An important phase in their history is a period of metamorphism[1] and thermoluminescence (TL) has proved a powerful technique for exploring this aspect, especially at the low end of the metamorphic spectrum[2]. The ordinary chondrites as a whole display a 10^5-fold range in TL sensitivity, while the least metamorphosed, or type 3, ordinary chondrites display a 10^3-fold range. Associated with this 10^3-fold range in TL sensitivity are variations in the temperature at which the maximum TL emission occurs, and in the temperature range over which emission occurs[3,4]. We report here the results of annealing experiments on a little-metamorphosed (type 3.5) ordinary chondrite. The TL emission characteristics of the annealed samples show trends very similar to those observed in meteorites which have naturally been metamorphosed to various extents. The trends are also similar to those observed in annealing experiments on terrestrial albite[5–7] where the changes are associated with the low-to high-temperature transformation. These data suggest that the TL phosphor in meteorites is feldspar and that TL can be used to estimate palaeotemperatures for little-metamorphosed and highly-unequilibrated meteorites.

About 1.5 g of the Allan Hills A77011 meteorite was ground (<100 μm) and the magnetic fraction removed. Aliquots weighing 20 mg were then placed in high-purity quartz vials, evacuated to 10^{-5} atmospheres, filled to atmospheric pressure with nitrogen and heat sealed. They were then placed in a wire-wound tube furnace at a variety of temperautres for 100 h. Two vials were annealed at each temperature. After annealing, the vials were allowed to cool in air, reaching room temperature after a few minutes. The TL induced by a 250-mCi ^{90}Sr β source (absorbed dose 25 krad) was then measured 3–5 times. (Our apparatus and techniques are described in ref. 4). Irradiation times were chosen so as to give a signal-to-noise ratio of better than 10, usually it was >50. Data for each vial were averaged and the standard deviation calculated. The data for a given time

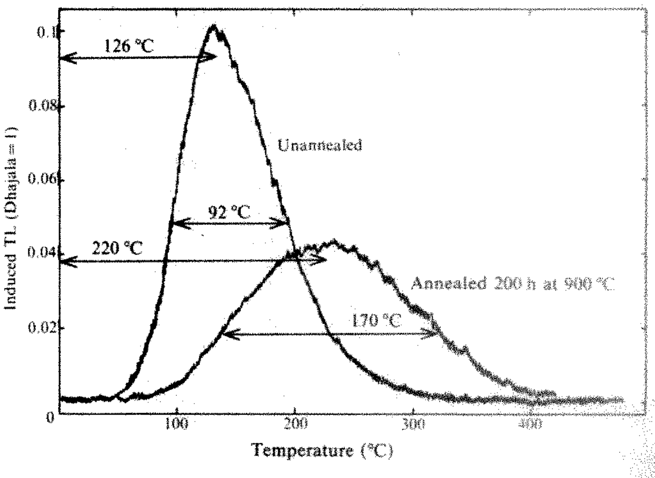

Fig. 1 Plots of the TL, induced by ^{90}Sr β radiation, against temperature for an unannealed sample of the Allan Hills A77011 meteorite, and a sample which has been annealed at 900 °C for 200 h. The annealing treatment has caused the TL peak, in fact, a composite of many smaller individual peaks, to broaden and move to higher temperatures.

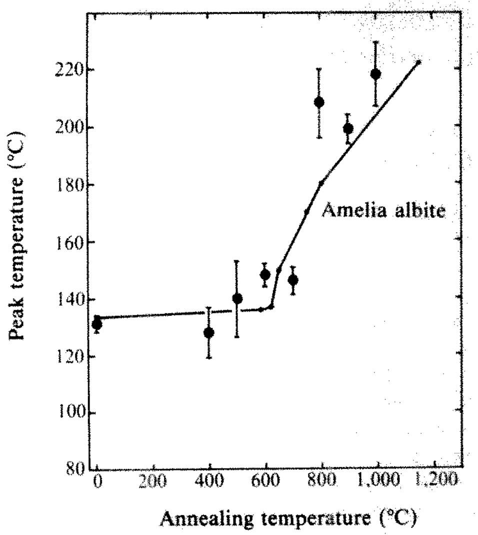

Fig. 2 A plot of the temperature of the TL peak against the temperature at which each sample was annealed for 100 h. The error bars refer to $\pm 1\sigma$ and each data point is the mean of two samples. Also shown are data from ref. 5 for a terrestrial albite from Amelia, Virginia, which was annealed for 24 h in a manner similar to that used here. The change in the TL emission characteristics of the Amelia albite were associated with the low-to-high temperature transformation, suggesting that the TL phosphor in meteorites is feldspar and that the shift in peak temperature on annealing may also be associated with changes in crystallography.

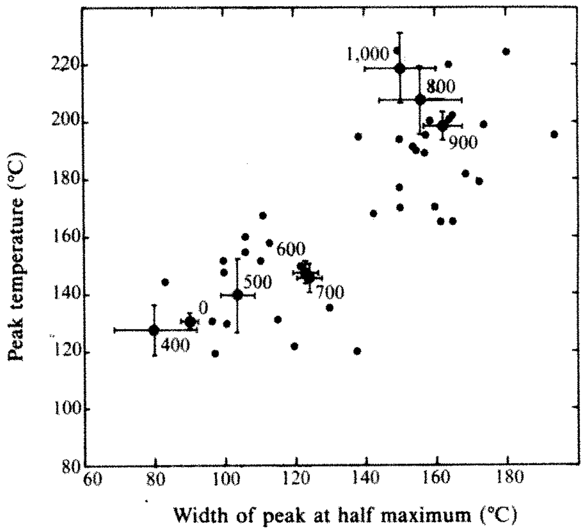

Fig. 3 Peak temperature plotted against the width of the TL peak at half its maximum intensity for the present data (large symbols) and for type 3 ordinary chondrites (small symbols, data from refs 3 and 4). Alongside the present data points are numbers indicating the temperature (°C) at which the samples were annealed for 100 h; 0 indicates the unannealed samples. Errors are $\pm 1\sigma$; two samples were run at each temperature. The meteorites show the same temperature–width relationship as the annealed samples, and the same tendency to bimodality, perhaps associated with the low- and high-temperature forms of the TL phosphor.

and temperature were averaged and the total uncertainty calculated by compounding the 1σ uncertainties for the replicate measurements on each vial and for the standard, Dhajala to facilitate comparison between different laboratories.

Two curves for the TL induced by the β irradiation as a function of glow curve temperature are presented in Fig. 1. Ordinary chondrites display a broad band of TL at 100–300 °C which is composite of many smaller, individual peaks. The glow curves for an unannealed sample and for one of our most severely annealed samples are shown in Fig. 1. The TL peak is relatively sharp in the unannealed sample and appears at a lower temperature in the glow curve than the TL peak of the annealed materials. In the examples in Fig. 1, the annealed sample has its peak 94 °C higher in the glow curve, and its peak is 78 °C wider at half its maximum intensity, than that of the unannealed sample. Our annealed samples in general have glow curves which resemble one or other of the curves in Fig. 1, the less severely annealed samples resembling the unannealed curve—with some variability in the width—and the more severely annealed samples resembling the annealed curve.

Figure 2 shows a plot of the peak temperature of the TL emission as a function of the temperature to which the samples have been annealed. (Peak temperature is that at which the TL emission is at a maximum.) There is a slight indication of a <20 °C increase in the position of the peak as the sample was annealed at temperatures up to 700 °C. The samples annealed at higher temperatures uniformly have TL peaks 80–100 °C higher than in the unannealed sample. We have also indicated on the plot Pasternak's data for samples of low albite from Amelia, Virginia[5–7]. Pasternak's samples were wrapped in Pt foil and annealed in He for 24 h. The agreement is striking and suggests that some change is occurring to the TL phosphor in both the feldspar and the meteorite between 600 and 800 °C. Pasternak performed X-ray diffraction studies on the Amelia albite and found that these changes in TL properties were associated with the transformation from the low-temperature (ordered) form to the high-temperature (disordered) form. However, the association was not a simple one as the TL changes occurred at faster rates than the order–disorder transformation; Pasternak suggests that the TL changes reflect crystallographic changes which precede the transformation, such as the formation of defects. The low to high transformation temperature in albite or meteoritic feldspar (oligoclase in equilibrated meteorites, but unknown in others) is poorly known, but appears to be between 500 and 700 °C in albite[8]. Kinetic factors complicate the comparison of the meteorite and the Amelia anealing data with the feldspar phase diagram, but if the TL changes are associated with known crystallographic changes in the phosphor, the possibility exists that TL can be used for geothermometry.

Feldspar has not been petrographically observed in meteorites of petrologic type 3.5 or lower, except as occasional grains of anorthite usually referred to a 'primary'. However, transmission electron microscope observations of feldspar have been made in meteorites of types >3.7 and feldspar is readily observable in types 5 and 6 where it seems to have formed by the devitrification of glass. Mineral separation experiments have shown that the TL phosphor is located in the low density, feldspar-rich component in equilibrated meteorites[9]. Therefore, we have previously suggested that the TL range in type 3 ordinary chondrites reflects progressive formation of feldspar by the devitrification of glass, and that the peak shape reflects the crystallography of the feldspar[3]. The present data are experimental evidence of that interpretation.

In Fig. 3 we compare the TL peak temperature with the width of the TL peak at half its maximum intensity. The data plot in two fields, the 800, 900 and 1,000 °C annealed samples have peaks at 200–220 °C and widths of 150–170 °C, while the unannealed and <700 °C annealed samples have peaks at 130–150 °C and widths of 80–120 °C. There seems to be a correlation between peak temperature and width for unannealed and <700 °C annealed samples. A ~50% increase in width corresponds to a ~15% increase in peak temperature. The change in peak width caused by the annealing treatment is, therefore, almost as marked as the change in peak position plotted in Fig. 2. We also plot in Fig. 3 data for 39 type 3 ordinary chondrites taken from refs 3 and 4. We have omitted meteorites with TL sensitivities <0.01 because the TL-peak position and TL-peak width relationships break down for these very low TL meteorites where we suspect that a different TL phosphor becomes important. The meteorite samples display the same general trend as our annealed samples, and show a tendency for the peak width and peak position to produce two clumps which may be related to the low- and high-temperature form of the TL phosphor. The data suggest that variations in thermal history are responsible for the peak position–peak width trends observed in type 3 ordinary chondrites[3] and that while some type 3 ordinary chondrites have experienced temperatures above 700 °C others have not. The trends in the chondrites are consistent with the idea that the least metamorphosed meteorites have a low-temperature form of feldspar as their TL phosphor. The implications of these data for our understanding of the metamorphic history of chondrites will be discussed elsewhere. However, one caveat is that our annealing times are very much less than the duration of metamorphism, but if, as we suspect, we are dealing with an equilibrium process, then laboratory measurements will be applicable. A study of the kinetics of the process is required.

Palaeothermometry of type 3 ordinary chondrites has always been a problem. The conventional approach of applying thermodynamic calculations to mineral pairs fails because the meteorites are non-equilibrium assemblages[10]. The oxygen-isotope thermometer works very well for petrologic types 4–6, but the heterogeneity problem is particularly acute for the type 3 chondrites because of the variable amounts of an ^{16}O-rich component[11,12]. We think that TL sensitivity may afford a new means of palaeothermometry in at least one rock type, the type 3 ordinary chondrites, where conventional methods fail. It might be usefully applied to other mildly metamorphosed rocks which contain feldspar as their dominant phosphor.

We thank the Meteorite Working Group of NASA/NSF for supplying the Allan Hills A77011 sample, P. K. Kuroda for interest and encouragement, N. Bakhtiar, B. Brandon, K. Saebo and K. Curtis for technical assistance and R. Hutchison and C. Melcher for constructive reviews. This work is supported by NASA grant NAG 9–81.

Seismic reflectors and unconformities at passive continental margins

J. Thorne & A. B. Watts

Lamont-Doherty Geological Observatory, and Department of
Geological Sciences, Columbia University, Palisades,
New York 10964, USA

Vail and co-workers[1–3] have recently suggested, based on seismic reflection data available to Exxon, that more than 25 global unconformities occur in Mesozoic–Tertiary age passive continental margins around the world. These data have been used to subdivide the stratigraphical record into several cycles, each of which is controlled by oscillatory changes in sea-level. The resulting scheme has been used as a basis to predict the stratigraphy of passive margins where there is little or no well control[4] or where few reflector terminations can be found[5]. We report here four difficulties with this scheme: (1) during times of minimal continental ice cover changes in the relative rate of sea-level are generally not sufficient to cause unconformities, except in old, slowly subsiding, margins; (2) seismic and biostratigraphical resolution restricts the identification of unconformity-bounded stratigraphical sequences to relatively few in continental shelves; (3) sequence boundaries appear to be best defined on slopes or in regions of active tectonic tilting; and (4) limitations in the sequence analysis technique preclude its use in predictive stratigraphy, especially in shelf and slope regions of margins.

Watts and Steckler[6] used the 'backstripping' equation to determine eustatic changes in sea level from the subsidence history of commercial wells drilled in the margin off North America. Assuming point-wise isostasy this equation can be written:

$$Y = S^* \left(\frac{\rho_m - \rho_s}{\rho_m - \rho_w}\right) + W_d + \Delta_{SL}\left(\frac{\rho_m}{\rho_m - \rho_w}\right) \qquad (1)$$

where Y is the tectonic subsidence of margin in water, W_d the water depth, Δ_{SL} the sea level with respect to present, S^* the uncompacted sedimentary thickness, and ρ_m, ρ_w, ρ_s are mantle, water and sediment densities respectively. Equation (1) can be used to assess the ability of sea-level changes to cause a non-depositional or erosional unconformity. The condition for non-deposition or erosion in submarine or sub-aerial environments is given (assuming an absence of significant variations in the rate of sediment supply to the shelf) by setting the rate of change in sediment thickness, S^*, to $\leqslant 0$. Equation (2) then becomes

$$\dot{\Delta}_{SL} \geqslant (\dot{Y} - \dot{W}_d)\left(\frac{\rho_m - \rho_w}{\rho_m}\right) \qquad (2)$$

where the overdot refers to the derivative with respect to time. Both $\dot{Y}$ and $\dot{W}_d$ can be reasonably well approximated in the case of a passive margin. The variation of tectonic subsidence with time, $\dot{Y}$, follows straightforwardly, for the thermal subsidence stage of a margin[7], from analytical expressions for the cooling by conduction of a plate or half-space[8]. In this study we assume for convenience the half-space approximation $Y = Kt^{1/2}$, where t is the age following rifting and K is a constant. Because of the assumption of a constant sediment supply rate, any deepening of the shelf ($\dot{W}_d > 0$) will necessarily cause sediments to infill. Therefore, the condition for sea-level changes to cause an unconformity on a subsiding margin is given by:

$$\dot{\Delta}_{SL} \geqslant \frac{K(\rho_m - \rho_w)}{2\rho_m}\, t^{-1/2} \qquad (3)$$

Minimum values of $\dot{\Delta}_{SL}$ that are necessary to create an Oligocene unconformity in different age margins are summarized in Table 1. This shows that relatively small values of $\dot{\Delta}_{SL}$ are required to form an Oligocene unconformity in an old passive margin while relatively large values are needed to form the same unconformity in a young margin.

Pitman and Golovchenko[9] have pointed out that among the possible mechanisms, only continental glaciation could cause changes in $\dot{\Delta}_{SL} \geqslant 1.2$ cm kyr^{-1}. Thus, in the absence of continental glaciation, an Oligocene unconformity would be expected at an old margin (for example, East Coast, US) but not at a young margin (for example, Norway). The occurrence of a prominent Oligocene unconformity in the margins of both the East Coast, US[10] and Norway[11] therefore implies continental glaciation during the Oligocene, a suggestion that is in accord with biogeographical evidence of the development of faunas and floras[12] as well as observations of enriched δ^{18}O values in deep-sea sediments[13]. It is unlikely, however, that all the Cenozoic unconformities mapped by Vail *et al.*[1–3] are caused by glaciation. The problem then is to explain the many major unconformities that appear in the Vail *et al.* scheme.

If the sequence boundary technique of Vail *et al.*[1–3] is to be a useful stratigraphical tool, then the major unconformities should be easily recognized within the resolution of seismic and biostratigraphical data.

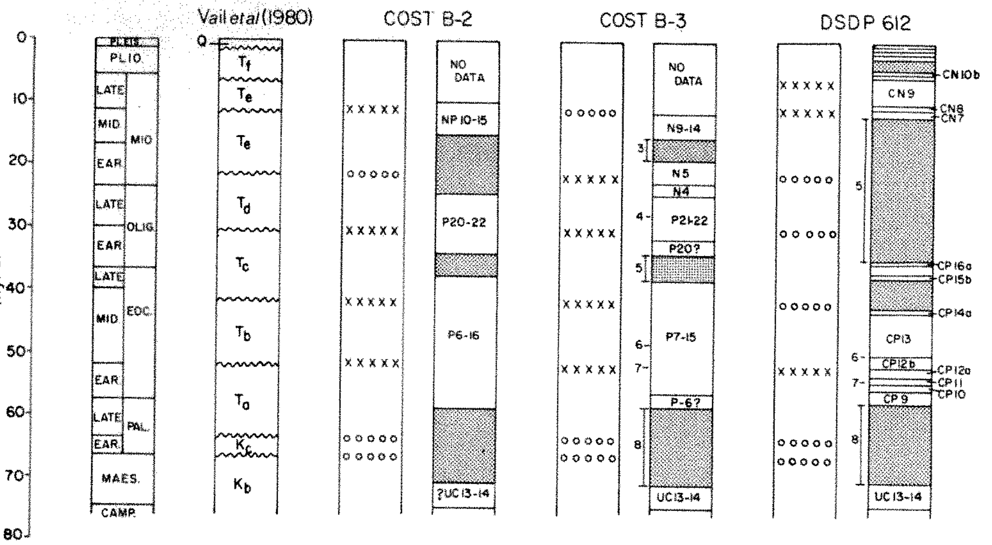

Fig. 1 Comparison of major unconformities predicted by the Vail *et al.*[1-3] scheme to biostratigraphical data at the COST B-2, B-3 and DSDP Site 612: ○ indicates that a short-lived erosional or non-depositional event could be present; × indicates that the predicted unconformity is absent. The position of seismic reflectors 3–8 (see Fig. 2) is also shown at the COST B-3 and DSDP Site 612. The depth to each reflector was computed from synthetic seismograms and travel-depth curves for COST B-3 (ref. 20) and at DSDP site 612 (ref. 21). Bars are used where a reflector spans an unconformity.

The essential problem in seismic sequence analysis is to have the necessary resolution in reflection profiles to identify reflector terminations against other prominent reflectors. Where terminations occur, reflectors split from a single horizon to a reflector pair. If the seismic resolution is poor, then this reflector pair may not be distinguished at any point across the shelf. In the Vail *et al.*[1-3] scheme, it is the differential subsidence across a passive margin during the time gap represented by the sequence boundaries that permits succeeding reflectors to be non-parallel. The average time gap that is observable on the shelf between reflectors above and below a sequence boundary represented by a single reflector termination is equal to the differential subsidence across the shelf divided by two. Table 2 shows the time that is necessary to meet this criteria assuming that the tectonic subsidence of a margin is given either by the half-space ($K = 350\,\mathrm{m\,.\,Myr^{-1/2}}$) or an exponential approximation, sediment loading occurs on an Airy-type crust, porosity falls off exponentially with depth, and the resolution of reflectors in two-way travel time is given by USGS multichannel seismic line 25 (ref. 14) of the US Atlantic shelf. Table 2 shows that within a wide range of assumptions, it is unlikely that seismic sequence analysis can resolve unconformities of ≤4 Myr duration on a thermally-subsiding continental shelf.

Biostratigraphical resolution is limited by the identification of distinct biozones in commercial, COST, and DSDP drill-holes. This is particularly a problem where the identification is based on samples from rotary cuttings. Figure 1 compares the major Cenozoic unconformities in the Vail *et al.*[2] scheme with biostratigraphical data at the COST B-2 (outer shelf), COST B-3 (upper slope) and DSDP Site 612 (middle slope) drill sites off New Jersey. In many cases, the time gap represented by the missing sedimentary section is large (5–10 biozones missing). Although it is relatively easy to identify these unconformities in biostratigraphical data, it would be difficult to estimate the times of the major changes in sea-level that may cause these unconformities with any accuracy. The biostratigraphical data in Fig. 1 is based on Poag[15] for the COST wells and the Scientific Party of DSDP Leg 95 (ref. 16) for Site 612. Since publication of these works, Poag[17] and Miller *et al.*[18] have suggested that the original biostratigraphy at the COST B-2 and B-3 may need to be revised. For example, they suggest that biozones P20 and P21a may be missing at these wells. If this is the case, then the unconformity at the T_c/T_d boundary may, in fact, be present. Figure 1 shows that, with the exception of the unconformities separating cycles T_c/K_b, T_a/K_b and K_c/K_b, the unconformities predicted by the scheme cannot be distinguished in published biostratigraphical data at the three drill sites. Thus, several major unconformities in the Vail *et al.*[2] scheme cannot be recognized in the East Coast US passive margin, even though there is a greater likelihood (Table 1) that sea-level changes will cause major unconformities at old, slowly subsiding, margins.

We have pointed out that rapid changes in sea-level sufficient to satisfy equation (3) are unlikely to create major unconformities that can be distinguished in shelf seismic and biostratigraphical data because of poor resolution. The problem still remains, therefore, that of explaining the large number of unconformities in the Vail *et al.*[1-3] scheme.

A significant number of unconformity-bounded stratigraphical sequences[11] can, in fact, be distinguished in USGS multichannel seismic line 25 of the East Coast, US passive margin. These sequences can only be observed in deep water in the vicinity of the COST B-3 well and Site 612 drill sites. As Fig. 2 shows, more unconformities are predicted by the Vail *et al.* scheme at the drill sites than are actually observed. Furthermore, of the observed sequence boundaries only two of the boundaries (5, 8) correspond to major unconformities. Of the other boundaries, one may represent an unconformity (3), three do not represent unconformities (4, 6, 7) and the remaining five are indeterminate. We call particular attention to sequence boundary 6 which is characterized by the most well defined pattern of reflector terminations on line 25. Evidence at DSDP Site 612 suggests that this reflector represents a post-depositional

Table 1 Rates of sea-level change required to produce a mid-Oligocene unconformity in different age passive continental margins

Age of rifting (Myr BP)	Time since rifting of mid-Oligocene 'event' (Myr)	Rate of change of sea level, Δ_{SL} (cm kyr^{-1}) $K = 295$ (m . Myr$^{-1/2}$)	$K = 350$ (m . Myr$^{-1/2}$)
186	156	0.81	0.97
130	100	1.02	1.21
100	70	1.22	1.44
60	30	1.86	2.20

* The values of K are based on the age–depth curves from refs 8, 19.

Table 2 Minimum length of unconformities for different age passive continental margins

Age of rifting (Myr BP)	Form of subsidence	Compaction depth constant (m)	Minimum length of unconformities (Myr) Age of horizon 30	60	90
186	$t^{1/2}$	2,500	4.1	8.9	9.1
186	Exponential*	2,500	5.5	4.3	5.0
186	Exponential*	1,000	7.8	7.0	8.9
100	$t^{1/2}$	2,500	4.0	7.9	7.2

* The total exponential subsidence was set equal to the $t^{1/2}$ case.

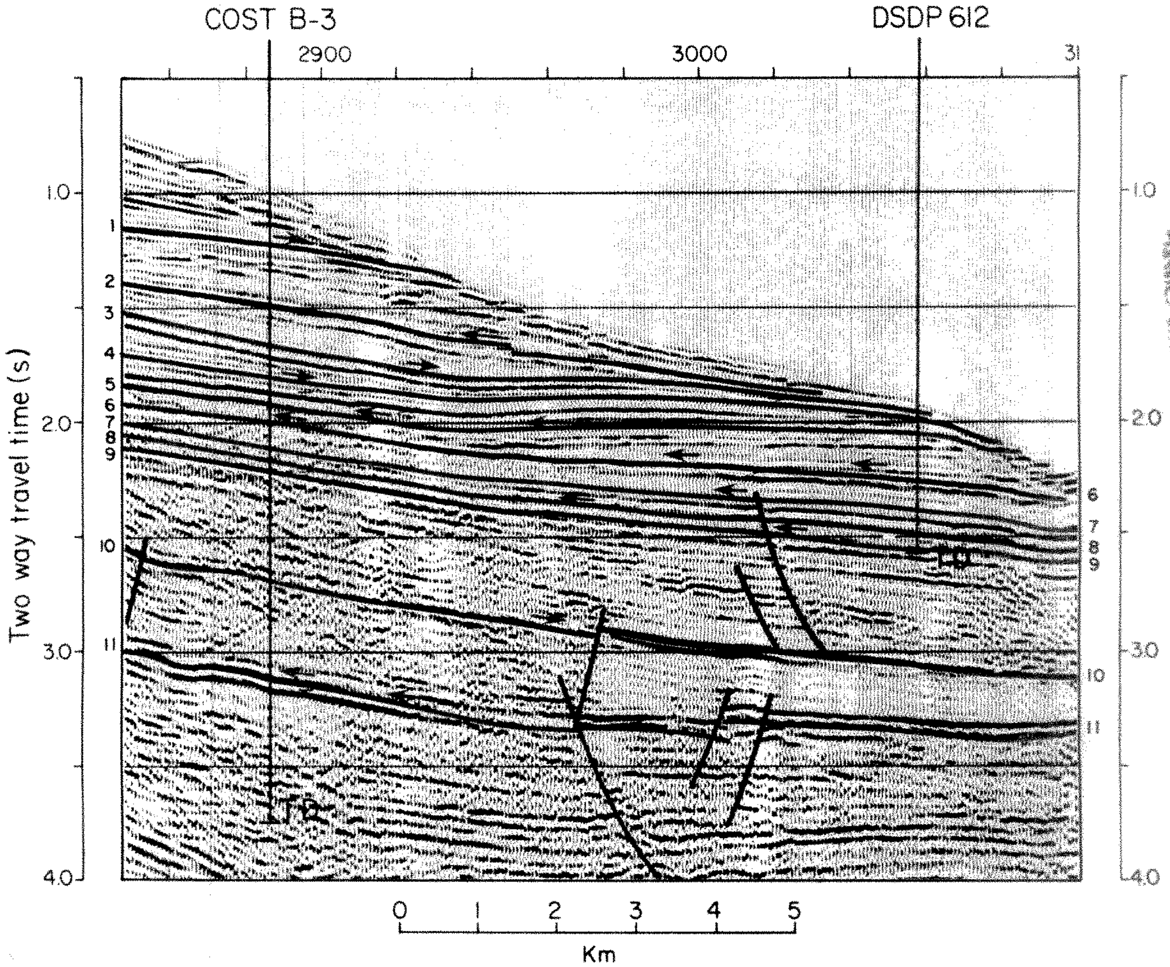

Fig. 2 USGS multichannel seismic line 25 (ref. 14) between shot-points 2847 to 3100. DSDP Site 612 (ref. 16) was drilled at 3558 on line 25. COST B-3 has been projected from 11 km to the north-east to 2885. The coloured reflectors 1–11 represent a preliminary interpretation consistent with the Vail *et al.*[1–3] scheme. Each sequence boundary is defined by reflector terminations (selected terminations shown by an arrow).

diagenetic front separating siliceous nannofossil chalk above from porcellanite below[16]. Although the origin of the front is unknown, it seems to be time-transgressive because it is observed just above the middle–early Eocene boundary at DSDP Site 612 and just below it at DSDP site 613 (ref. 16), drilled 11.5 km downslope of Site 612. The superposition of a diagenetic reflector at an angle to bedding plane reflectors may, therefore, have created the apparent pattern of onlap in Fig. 2. Reflectors should, in theory, be observed to continue across reflector 6. In practice, however, poor seismic resolution makes such an identification difficult.

It is, therefore, unclear which factors control the sequence boundaries on multichannel seismic line 25. We point out, however, that the sequence boundaries can only be easily recognized on the slope part of line 25 and that palaeoceanographic conditions may control at least part of these sequences.

Vail *et al.*[1–3] have repeatedly pointed out the limitations of the seismic sequence analysis technique. We have shown that these limitations may be made more severe by the pattern of subsidence that characterize passive margin development. Because the technique of predictive stratigraphy requires that all or most of the sequence boundaries can be easily recognized in an observed basin section, these limitations suggest caution if they are to be used in age correlation. For example, prominent seismic reflectors of the Barents shelf were 'dated' by Jørgensen and Navrestad[4] based on the Vail *et al.*[1–3] scheme. We caution against too literal an interpretation of these dates until the sedimentary sequences are actually drilled.

As a tool in predictive stratigraphy, it is commonly assumed that the Vail *et al.*[1–3] curve of changes in sea-level is applicable worldwide. We point out, however, that the nature of the control on stratigraphical sequences is unclear. Thus, this assumption should be vigorously tested in the future.

Seismic sequence boundary techniques have proved a valuable tool in quantitative stratigraphy. We have pointed out that the number of sequence boundaries that can be attributed to changes in the rate of sea-level is probably less than previously thought. We have shown that slowly varying changes in sea level can cause major unconformities of wide extent on the shelf, particularly at relatively old passive margins. However, we do not expect that this mechanism can explain many unconformities on the slope. Alternative explanations, therefore, need to be sought for sequence boundaries on the slope, only some of which extend to the shelf. Future studies that include the effects of changes in sediment supply, ocean-wide tectonics, lithospheric mechanics, and palaeoceanographic effects offer the most promise of addressing the unconformity problem in the future.

Evolution of the lower continental crust: granulite facies xenoliths from the Eifel, West Germany

H.-G. Stosch & G. W. Lugmair

Scripps Institution of Oceanography, University of California
at San Diego, La Jolla, California 92093, USA

The lower continental crust is a key region to understanding processes of crust–mantle differentiation and subsequent evolution of the crust. The region is metamorphosed into granulite or amphibolite facies[1,2]. Whereas felsic to mafic granulites with an average intermediate major element composition are typically observed in old exposed lower crustal terranes, mafic compositions are preponderant among granulite facies xenoliths transported by young alkalic basaltic volcanics and kimberlites[1]. Radiometric ages for granulite bulk rocks using the Rb–Sr or U–Pb methods are usually interpreted as metamorphic ages. In contrast, Sm–Nd ages obtained on such metamorphics are interpreted to reflect pre-metamorphic events[3–7], although a case of severe disturbance of the Sm–Nd isotope system during granulite facies metamorphism has also been reported[8]. We present here Sm–Nd and Rb–Sr isotope data for a suite of mafic lower crustal xenoliths from the Hercynian belt. Our data suggest that the igneous precursors of these granulites differentiated from depleted mantle ~1.5 Gyr ago. In most of these granulites this evidence for a mid-Proterozoic age has been obliterated by a young (<172 Myr) metasomatic overprint by mantle derived fluids or melts.

The suite of lower crustal granulite facies xenoliths found in Pleistocene alkalic basaltic tuffs near Engeln/Eifel (Germany) has previously been investigated petrographically and chemically[9,10]. It has been suggested that these granulites are part of the Pleistocene deep crust and form a rather thin layer directly above the Moho[9,10] at ~30 km depth[11]. These xenoliths lack foliation typical of gneiss[9]. Their chemical composition is invariably 'basaltic' favouring an igneous rather than sedimentary origin of the granulite protoliths. On geological grounds the age of the granulite facies metamorphism must have been at least Caledonian[9,10]. A retrograde amphibolite facies metamorphic overprint evidenced by the formation of reaction coronas around garnets was attributed to crustal thinning and/or uplifting during the Hercynian orogeny[9]. The mineralogy of the granulites from Engeln as described by previous investigators is plagioclase ± clinopyroxene ± garnet ± orthopyroxene ± scapolite ± amphibole. Amphibole is ubiquitous in these nominally dry rocks and highly variable in modal abundance (<1–~40%). Texturally the amphibole is clearly secondary in many cases where it formed at the expense of clinopyroxene whereas in other cases amphibole appears to be primary (for example, ref. 9 and own observations).

The results of our analysis of 10 granulites plus one upper mantle spinel peridotite from Engeln/Eifel are presented in Table 1. The presence of amphibole and a pronounced relative light rare earth element (REE) enrichment, classify this mantle xenolith as 'metasomatized', similar to a suite of spinel peridotites from Dreiser Weiher/Eifel[12]. To characterize the local upper crust, we have also analysed one small (~2 cm) sedimentary inclusion (Lower Devonian?) from a basanite flow near Uedersdorf/Eifel as well as one sample of Lower Devonian shale outcropping nearby. The purpose was to possibly obtain information on the crustal residence time of the igneous precursors of these sediments by using the Sm–Nd isotopic system. This follows the approach of McCulloch and Wasserburg[27] and O'Nions and coworkers[21,28].

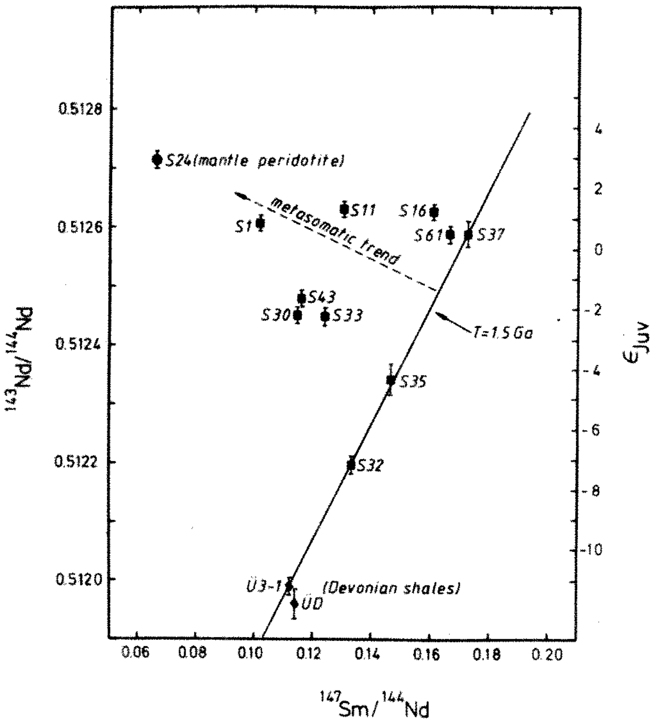

Fig. 1 Sm–Nd isotope evolution diagram for granulites, one peridotite and sediments. An age of ~1.5 Gyr is inferred for a crust forming event involving depleted mantle with $\varepsilon_{JUV}(T) \sim +5$. The arrow indicates the direction of Nd isotopic displacement of parts of the lower crust underneath the Eifel towards mantle values due to metasomatism with mantle derived fluids. This also led to a further light REE enrichment.

The Sr isotopic composition of the mantle peridotite S24 is similar to that reported previously for amphibole-bearing spinel peridotites from Eifel[13]. ^{87}Sr/^{86}Sr of the granulite xenoliths ranges from typical mantle (~0.7036) to crustal values (~0.7095). Rb concentrations and Rb/Sr ratios are among the lowest reported for granulite facies metamorphics so far. The highest Rb concentrations are found in the granulites with the highest modal abundances of amphibole. Due to the overall low Rb/Sr ratios ^{87}Sr/^{86}Sr is essentially frozen, and thus does not allow time constraints to be placed on metamorphic or other events. While the small Rb/Sr ratios of the granulites with low ^{87}Sr/^{86}Sr may have been established during formation of their igneous precursors, high ^{87}Sr/^{86}Sr require that samples like S32 evolved with high Rb/Sr for a considerable time. These data therefore support interpretations similar to those applied to Archaean high-grade metamorphic terranes that Rb, among other elements, can be highly mobile and partly lost during granulite facies metamorphism[14–16]. The two upper crustal sediments have high ^{87}Sr/^{86}Sr and Rb/Sr ratios, attesting to the generally enriched nature of the heavy alkalies in the upper relative to the lower crust.

The Sm–Nd isotopic results given in Table 1 are plotted in Fig. 1 as an isotope evolution diagram. For the granulites two trends can be separated. One trend runs from S35 or from S37 towards the metasomatized spinel peridotite S24, with an inverse correlation between Sm/Nd and ^{143}Nd/^{144}Nd. More specifically, the direction of the trend is from typical crustal Nd isotopic

Isotopic fractionation was corrected to $^{86}Sr/^{88}Sr = 0.1194$ and $^{148}Nd/^{144}Nd = 0.241572$; Nd was measured as NdO^+; $^{87}Sr/^{86}Sr = 0.71026$ measured for NBS987 Sr and $^{143}Nd/^{144}Nd = 0.511859$ for the La Jolla Nd standard.

* Uncertainties for concentrations: [Rb] ± 0.5%, [Sr] < ±0.2%, [Sm] and [Nd] < ±0.1%.

† In most instances actual in-run errors are smaller than quoted; minimum errors given are derived from external precision of standard measurements which are 37 and 27 p.p.m. for $^{87}Sr/^{86}Sr$ and $^{143}Nd/^{144}Nd$, respectively.

‡ Present-day $^{143}Nd/^{144}Nd$ for JUVINAS is 0.512566 ($\varepsilon_{JUV}(0) \equiv 0$).

$$\varepsilon_{JUV}(0) = \left[\frac{^{143}Nd/^{144}Nd^{\text{measured}}_{\text{sample}}}{^{143}Nd/^{144}Nd^{\text{present}}_{\text{JUVINAS}}} - 1 \right] \times 10^4$$

values to values found for metasomatized mantle spinel peridotites (see also ref. 13). Along this trend the modal content of amphibole increases from <5% in S35 to 30–40% in S30. Large ion lithophile element-rich fluids or liquids originating in the mantle probably reacted with the granulites to a variable degree. This trend, therefore, is the result of extensive metasomatism which also is responsible for further light REE enrichment. The time at which the metasomatic modification of an originally dry into hydrous (amphibole and/or phlogopite containing) upper mantle occurred was previously estimated for this region to be <200 Myr ago[13].

Sm–Nd data for plagioclase, clinopyroxene and garnet from granulite S30 (see Table 2 and Fig. 2) form an isochron with a slope corresponding to an age of 172 ± 5 Myr. The data for amphibole as well as the bulk rock, however, are clearly above the isochron. They are displaced towards values for amphibole-bearing mantle peridotites from the Eifel but not towards values for the crust in this area which, at a similar Sm/Nd ratio, would be below the isochron. The same argument holds true for $^{87}Sr/^{86}Sr$. Amphibole (~0.7054) is displaced towards mantle values relative to clinopyroxene and plagioclase (~0.7061 for both minerals). The data point for S30-bulk in Fig. 2 is almost identical to that for S30-amphibole because by mass balance the amphibole accounts for some $\frac{2}{3}$ of this rock's total Nd content. This strongly supports our interpretation that the formation of amphibole in these granulites is due to metasomatism by mantle-derived fluids. The age of this mineral isochron can be regarded as a maximum age for the formation of amphibole and, hence, metasomatism in the lower crust.

The evidence for metasomatic modification of the lower crust clearly indicates that any information on the timing of pre-metasomatic events can only be obtained from those granulite xenoliths which are farthest removed from values for metasomatized mantle in Fig. 1, that is, granulites S32, S35 and S37. These three data points plot along a line with a slope corresponding to an age of 1.5 ± 0.1 Gyr and an initial $\varepsilon_{JUV}(T) = +4.7 \pm 1.9$. We interpret this as evidence that part of the lower crust beneath the Rhenish Shield differentiated from depleted mantle at around this time. Of course, neither the igneous age nor the initial ε_{JUV} of these rocks are tightly constrained by the three data points. Nevertheless, the isochron appears to be real since no mixing relationships can be derived from our isotopic and elemental abundance data. This evidence strongly contradicts the still widely held view that the continental crust in the Hercynian belt in Central Europe is not older than ~700 Myr (refs 17, 18). Additional support comes from U–Pb studies on zircons from the Hercynian fold-belt in Europe which yield even older ages, between 1.9 and 2.2 Gyr (refs 18, 19).

From Fig. 1 it is apparent that the data for the Devonian sediments ÜD and Ü3-1 plot on or close to the line through the data points for granulites S37, S35 and S32, that is their Sm–Nd isotope systematics are consistent with their having about the same 'age' as the granulites. It is worth noting here that loess deposits from Central Europe have Sm–Nd depleted mantle model ages around 1.5 Gyr (ref. 20). Fine-grained clastic sediments from the British Isles south of the late Precambrian to early Palaeozoic Iapetus Ocean have very uniform Sm–Nd depleted mantle model ages around 1.7 Gyr (ref. 21), that is, only slightly higher than the age obtained by us for the Eifel rocks. Both types of sediments probably provide good averages of their upper crustal sources with respect to Sm/Nd ratios, and $^{143}Nd/^{144}Nd$ compositions which can be used to estimate their crustal residence ages. Although it may be fortuitous that the sediment data fall on or close to the line through the data for the granulites in Fig. 1, we consider that the igneous precursors of granulites and sediments have been extracted from the mantle at around the same time, that is towards the end of the ~1.6–2-Gyr tectonothermal event which affected wide parts of the Baltic

Table 2 Sm–Nd results for separated minerals from granulite S30

	Sm [p.p.m.]	Nd	$^{147}Sm/^{144}Nd$	$^{143}Nd/^{144}Nd$	$\varepsilon_{JUV}(0)$
Amphibole	11.81	59.0	0.1211 ± 1	0.512456 ± 14	−2.1 ± 0.3
Clinopyroxene	4.97	22.65	0.1326 ± 1	0.512415 ± 14	−2.9 ± 0.3
Garnet	1.824	1.007	1.095 ± 1	0.513499 ± 30	+18.2 ± 0.6
Plagioclase	0.1831	2.804	0.03946 ± 8	0.512306 ± 24	−5.1 ± 0.5

Conditions and methods as in Table 1.

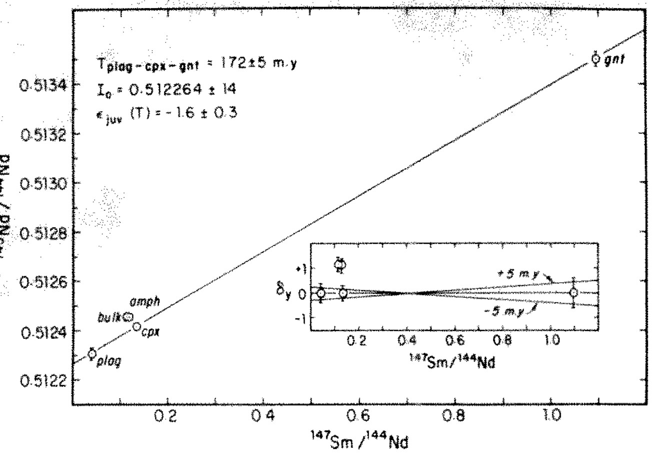

Fig. 2 Sm–Nd isochron diagram for separated minerals from granulite S30 (plag, plagioclase; cpx, clinopyroxene; amph, amphibole; gnt, garnet). All minerals have been hand-picked and etched in dilute HCl and HF prior to dissolution to ensure absence of any contaminants. Inset shows deviation (δy) in parts of 10,000 of the data from the best fit-line through plagioclase, clinopyroxene and garnet.

and Laurentian Shields[22]. Our argument, particularly with regard to involvement of depleted mantle, is further strengthened by the high value of $\varepsilon_{\text{JUV}}(T)$. This value is practically identical to the $\varepsilon_{\text{JUV}}(T)$ indicated for depleted mantle underlying parts of the North American continent[23,24] and Greenland[24] and suggests a relatively large-scale Nd isotopic homogeneity in the upper mantle at around this time. Our isotope data for the Eifel samples add further constraints to the understanding of the derivation through time of continental crust from progressively depleted mantle.

Metamorphic events in the lower crust under the Eifel do not seem to have severely affected the Sm–Nd isotope systematics, in agreement with previous suggestions that the Sm–Nd clock can survive even granulite facies metamorphism[4–7]. The age of the event which metamorphosed the deep crust under the Eifel into granulite facies cannot be disclosed by our Sm–Nd data. However, a Caledonian or older age of the high-grade metamorphism[9,10] cannot be confirmed by our Sm–Nd or Rb–Sr data. In contrast, the results from the mineral isochron (Fig. 2) require Mesozoic ages to be considered as well.

We have suggested that relatively young metasomatism has transported large ion lithophile elements (probably along with volatiles like CO_2 or H_2O) from the mantle into ~1.5 Gyr-old lower crust leading to the formation of amphibole in previously dry granulites. In the case of the Eifel, this has resulted in shifts from crustal to near bulk Earth Sr and Nd isotopic compositions for the majority of the analysed granulites (average $^{87}Sr/^{86}Sr \sim 0.7048$, average $\varepsilon_{\text{JUV}} \sim -1$ for all granulites not lying on the isochron in Fig. 1). This shift represents an isotopic rejuvenation of the lower crust.

Metasomatism is well known from mantle xenoliths of worldwide occurrence, making depleted mantle fertile with respect to its capability to produce alkalic basaltic melts[25]. If, as described here for the Eifel, metasomatic modification by mantle derived fluids or melts is widespread in the lower crust, at least in regions of continental rifting or uplift, it will become necessary to view certain aspects of the evolution of the continental crust (for example, the origin of felsic plutonic rocks, with mantle initial $^{87}Sr/^{86}Sr$ and $^{143}Nd/^{144}Nd$ values) also within the context of derivation from metasomatized lower crust[26].

The granulite xenoliths came from the collection of the Mineralogy-Petrography Institut/University of Cologne. We thank H. A. Seck for valuable discussions and J. Mahoney for help with various analytical aspects. This research was supported by grants from DFG to H. A. Seck and NSF EAR8213670. SIO-IG²L contribution no. 22.

Relationship between continental area and elevation

Antony R. Wyatt

Department of Geology, University College of Wales, Aberystwyth,
Dyfed SY23 3DB, UK

Continental hypsographic curves, derived from data gathered by Kossinna[1], show a similarity of shape that suggests a correlation between continental area (including the continental shelf) and average height[2,3]. I have considered the varied geological histories of the continental blocks and suggest here that this relationship is not fortuitous, and that changes in continental groupings will have profound effects not only on ocean volumes, and hence sea level, but also on the three-dimensional shapes of the continental blocks.

Harrison *et al.*[2] consider that the apparent link between area and elevation can best be expressed in the form

$$h = -0.4623 + 0.3731 \log_e A \qquad (1)$$

where h is the height (in km) above the continental shelf edge (taken as 200 m below sea level), and A (in Mm^2) is the continental area. This expression was used to derive a theoretical hypsographic curve for Pangaea to explain the lower than otherwise expected areal flooding during eustatic rises of sea level.

This expression was calculated using data from Kossinna[1], but Harrison *et al.*[3] have recently produced more detailed data that would modify this relationship. From a geological point of view the geographer's continental masses have to be regrouped to conform with what is known of crustal movements (see refs 4, 5). The major changes necessary involve the combination of the values for Europe and most of Asia, which appear to have acted as a block for the Mesozoic and Cenozoic, and the removal from Asia of the Arabian Peninsula, which seems to belong more to the African continent. The collision zone of India and Eurasia is complex, and may include other continental fragments[6] and much underthrusting. The data of Harrison *et al.*[3] suggest how the volume of underthrust crust may be estimated, but it is not possible to resolve this into a simple set of area/height data for a separate India. I have, therefore, included India with Eurasia. Details of the hypsographic curves for the rock surfaces of Antarctica and Greenland are not known to

Table 1 Elevation and area data for present continental masses

Continent	Average height (m)	Area (10^{12} m^2)	Average thickness (km)	Volume (10^{12} m^3)
Eurasia	834	59.92	37.2	2,227,750
Afrabia	824	34.82	37.1	1,292,500
North America	699	26.74	36.3	971,250
South America	723	20.10	36.5	733,000
Australia	443	11.12	34.7	385,750
Total		152.70		5,610,250
Antarctica		13.68		484,250
Greenland		2.56		84,500
Total		168.94		6,179,000

Data are based in part on ref. 3. Average heights are above 200 m below present sea level. Average thickness calculated as shown in the text. Volumes given to the nearest 250×10^{12} m^3. Data for Antarctica and Greenland are less reliable than that for the other continental masses.

any great accuracy (estimates of the average elevation of the Antarctic ice cap range from 785 to 2,200 m), and therefore are not used in the calculations below. Harrison *et al.*[3] have separated Madagascar from the rest of Africa. There is still controversy over the nature of the Mozambique channel, and it also looks as if part of the Madagascar Ridge may be thin continental crust[7], which would change the average elevation of the Madagascar block considerably. These data have, therefore, also been left out of the calculations.

The average total thickness of a continental block was calculated assuming that the blocks are in approximate isostatic equilibrium (Fig. 1). Taking average values for the density of continental crust (2.782 g cm^{-3}), oceanic crust (2.9 g cm^{-3}) and seawater (1.03 g cm^{-3})[8] it is possible to derive a simple formula relating the average height of a block to the average depth of its root. For isostatic equilibrium

$$d_w h_4 + d_c h_2 + d_m h_3 = d_c h_1 + d_c h_2 + d_c h_3$$

or

$$h_3 = 5.37 h_1 - 0.398 \qquad (2)$$

It is also possible to derive an expression for the thickness of continental crust below a continent of average height 200 m below sea level. Additional assumptions are the average depth of old oceanic crust (6,400 m below sea level)[9] and the average thickness of oceanic crust (6,600 m)[10]. For isostatic equilibrium

$$d_c(h_5 - h_4) + d_c h_6 + d_c h_7 = d_w(h_5 - h_4) + d_0 h_6 + d_m h_7$$

or

$$h_7 = 19.466 \text{ km}$$

then

$$h_2 = 32.266 \text{ km}$$

Thus, the total thickness of continental crust of a continent of average height h, will be given by the expression

$$\text{Total thickness} = 31.868 + 6.37h \text{ km} \qquad (3)$$

Table 1 lists the revised average height and area figures, the total thickness calculated using equation (3), and the total volume of continental crust for each block. Figure 2 shows average height plotted against area for the blocks with good data, with a curve fitted to these points. Figure 2 suggests that the relationship is better expressed as

$$h = -0.045 + 0.2294 \log_e A \qquad (4)$$

Both the curve fitted to the data in Fig. 2, and the expression derived by Harrison *et al.*[2], have an interesting consequence. If the relationship has held throughout geological time, then the average elevation of the supercontinents must have been greater than that of the fragments we now see. And if the average height

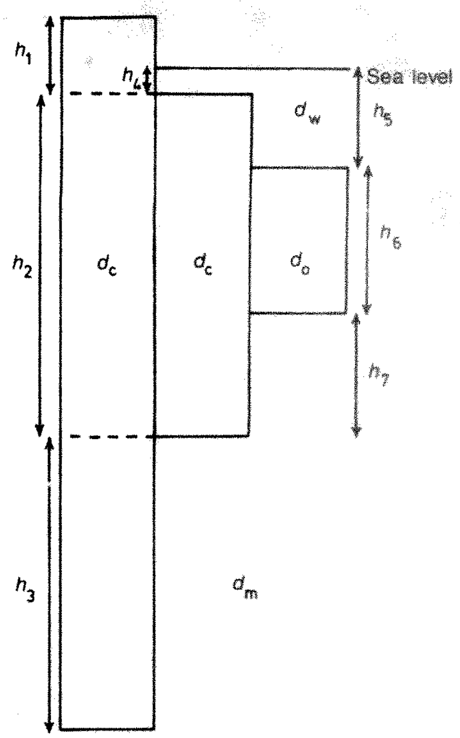

Fig. 1 Blocks in isostatic equilibrium. d_i, Density of material i, where c, continental crust; m, mantle; o, oceanic crust; w, seawater.

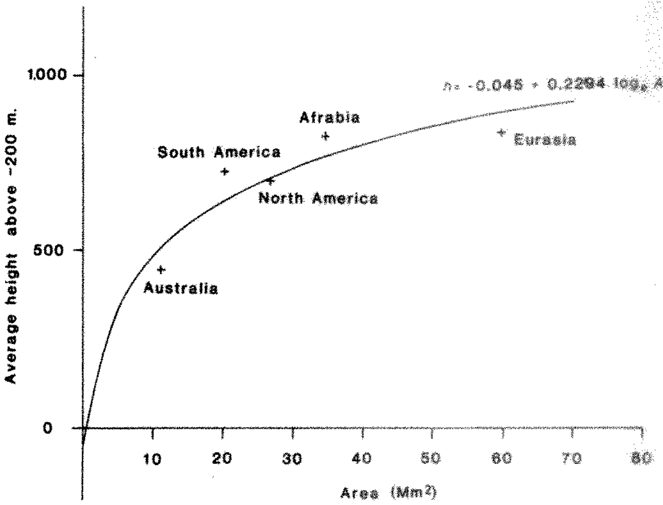

Fig. 2 Relationship between average height and area for those continental blocks with reliable data. The regression line is fitted by least squares.

was greater, the depth of the continental crust must also have been greater to preserve isostatic equilibrium. Unless we invoke changes in the volume of continental crust in parallel with the formation and splitting of continental blocks, this implies changes with time in the area of the globe covered by continental crust. There are sound geochemical arguments showing that the total volume of continental crust has remained almost constant for at least the Phanerozoic, and probably much longer, so it is possible to plot the relationship of volume to area and to calculate the changes in total area of the globe covered by continental crust with different continental groupings.

The relationship of volume to area is given by

$$\begin{aligned} V &= (31.868 + 6.37h)A \\ &= (31.581 + 1.4613 \log_e A)A \qquad (5) \end{aligned}$$

This relationship is plotted on Fig. 3. The numerical values in the expression are dependent on the values for densities and

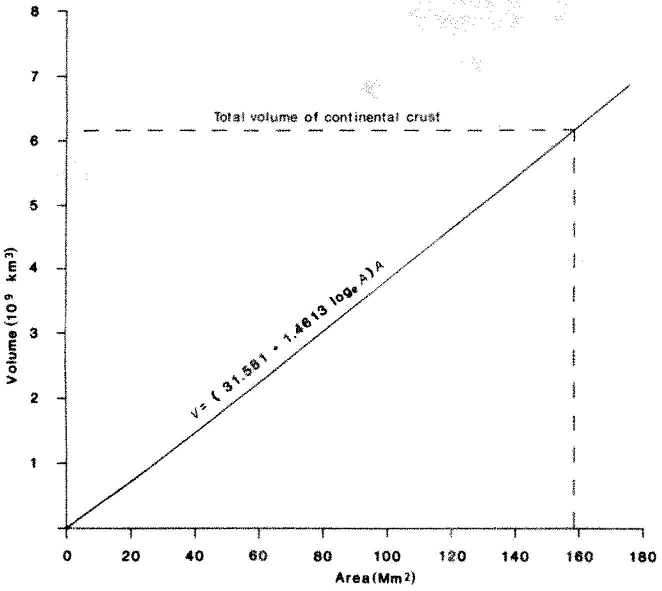

Fig. 3 The theoretical relationship between the volume of a continental block and its surface area.

depths, but slight variation in these values does not affect the conclusions drawn below. From equations (4) and (5) it is possible to calculate theoretical values for the average height and volume of Antarctica and Greenland. These are listed in Table 1, and used simply because they will act in the same way as the other continental blocks.

Figure 3 shows that if all the continental crust formed one block, the total area covered would be ~158.5 Mm^2. This may represent the situation in the early Mesozoic when Pangaea was extant. This is considerably smaller than the present total area covered by continental crust which is about 168.9 Mm^2 (Table 1). This implies that the volume of the ocean basins in the early Mesozoic was ~66.6 × 10^6 km^3 more than it is at present, before allowing for isostatic adjustment due to smaller water load. This is equivalent, after isostatic adjustment, to a sea level some 125 m below the present level.

As Pangaea broke up into smaller fragments these would have altered their configuration to conform with equation (4) that is, the area of a given fragment would increase as its height (and thickness) decreased until it reached a new stable state. Such changes in the area of the continental fragments would have affected the volume of the ocean basins, not only directly, but also by increase in subduction rates and/or decrease in the rate of creation of new crust at ridges, with associated changes in sea level. It may be possible to estimate the rates involved in this flattening process by looking at the history of small fragments of continental crust that have become detached from larger units, as the model suggests that their average height should be much less than that of the parent unit. Berggren[11], for example, suggests, on the basis of microfauna from JOIDES samples, that the Rockall Bank area sank by ~600 m in a time span of some 6 Myr in the Palaeogene. The geological history of some of the microcontinents in the South European Tethys may record the opposite process, as may the late Cenozoic history of the Indian continental crust.

In addition to predicting changes in sea level the model shows that a large continent will have a smaller area of shallow sea than several smaller continents with a total area equal to the large continent. A rough calculation based on a continent of area 158.5 Mm^2 suggests a shallow sea area (that is down to about 200 m below the sea level) of about 13 Mm^2, which is about half the area of modern shallow seas. This has important consequences for evolutionary studies.

The model poses problems for palaeocontinental reconstruction, as it predicts different depth compensation histories for different sized fragments, as well as expansion of the fragments. This may go some way to resolving problems associated with expanding Earth hypotheses, as it suggests that the continents have generally increased their areal extent since the breakup of Pangaea. The Palaeozoic history of the continental blocks should, in general, show the opposite effect.

Cogley[12] has produced an independent reassessment of continental area and height relationships. He recognizes more continental blocks than those used above, suggesting that the total area of continental crust is considerably greater, but his data suggest a similar relationship between mean height and continental area. Modal heights do not show such a simple relationship, suggesting that calculations of shallow sea areas are not as straightforward as might be expected.

I thank Dr. C. G. A. Harrison for useful comments.

A lower crustal origin for massif-type anorthosites

S. R. Taylor, I. H. Campbell, M. T. McCulloch & S. M. McLennan

Research School of Earth Sciences, The Australian National University, Canberra, ACT 2601, Australia

The origin of batholith-sized masses of plagioclase-rich crustal rocks, mainly Proterozoic in age, has mostly been ascribed to aluminous magmas of mantle derivation. Here we propose that such masses are derived by partial melting of an aluminous lower continental crust, which has developed following extraction of a granitic upper crust by intra-crustal melting. This segregation of upper and lower crusts occurred principally in the late Archaean. As the lower crust was depleted in heat-producing elements during the initial melting to produce granites, an external source of heat is required to produce Proterozoic massif-type anorthosites. We speculate that this heat resulted from the continental crust moving over a mantle hotspot or line plume.

Anorthosites may be classified broadly into two types: Archaean and massif. The Archaean anorthosites typically occur as components of layered igneous intrusions[1] of moderate size and are clearly of mantle origin. Plagioclase compositions lie in the range An_{80-95}. In contrast, the massif-type anorthosites which occur as large batholith masses up to 30,000 km^2 in outcrop area, present major petrological and geochemical problems[2–9]. Plagioclase compositions are intermediate, typically An_{40-60} and Mg/(Mg + Fe) ratios are in the range 40–50. Their isotopic characteristics are enigmatic[9]. They are notably depleted in Rb with very low Rb/Sr ratios. Typical initial $^{87}Sr/^{86}Sr$ ratios are low but variable, ranging from 0.7025 to 0.7070, unsupported in many examples by the present Rb/Sr ratios. ε_{Nd} values are even more erratic varying from enriched (−6) to depleted (+4) sources[9]. The bulk composition displays enrichment in Eu relative to the other chondrite-normalized rare-earth elements (REE) (Fig. 1). In addition to their petrological and geochemical

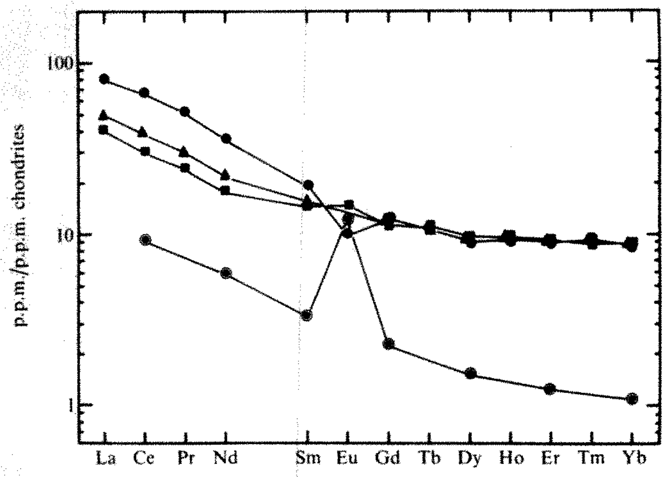

Fig. 1 Chondrite-normalized REE diagram for upper (●), lower (■) and total (▲) continental crust[12]. Also shown is a typical Proterozoic anorthosite pattern (⊙).

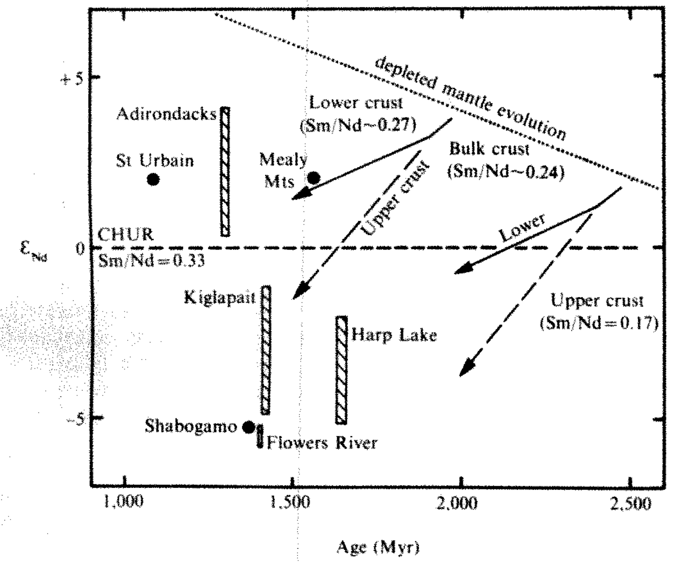

Fig. 2 Fractional deviations from CHUR (chondritic reservoir) in parts per 10^4 of initial ^{143}Nd/^{144}Nd (ε_{Nd}) in Proterozoic anorthosites[1,8]. Also shown are the evolutions of depleted mantle and lower, upper and bulk crust. The range in ε_{Nd} values of the anorthosites is compatible with a 300–500 Myr residence period in the lower crust.

peculiarities, they are primarily a Proterozoic phenomenon, mostly intruded between about 1,700 and 900 Myr ago. Massif-type anorthosites also seem to be related to unique tectonic conditions during the Proterozoic, occurring at sites of incipient or failed continental rifting[5,8,10,11].

We believe that the high Al content, the low An content of the plagioclase and the low Mg/(Mg+Fe) of these rocks is incompatible with a mantle source for Proterozoic massif anorthosites, and now suggest that they are derived from the lower crust. In the model[12–14] that we adopt for the development of the continental crust, a massive increase in continental volume occurred between about 3,000 and 2,500 Myr followed closely by a large intra-crustal melting event which produced enough K-granites to dominate the composition of the upper crust. Thus, the lower crust becomes both dry and depleted in K, Rb, U, Th and the other elements concentrated in granitic melts (Table 1); it also becomes enriched in Al, Sr and Eu (Fig. 1), so that there is an overall enrichment in Eu, relative to chondrite-normalized REE patterns, and the development of low Rb/Sr ratios.

The model composition for the bulk lower crust is given in Table 1. This shows a low quartz and orthoclase content, due to previous extraction of granitic melt. COCORP studies[15] show that the composition of the lower crust is complex. Accordingly, many regions of the lower crust will be even more basic (as shown by many lower crustal xenoliths) and be an appropriate source for the mafic minerals in the massif anorthosites. From our model we predict that anorthosites should possess mineralogical, isotopic and chemical variations which reflect the lower crustal heterogeneity. Although earlier workers[16,17] have suggested that intracrustal melting would produce anorthosites, this proposal differs in specifying an Al- and Eu-rich lower crust residual from the melting episodes which produced a granodioritic upper crust.

Table 1 A model composition of the lower crust[12]

	(%)		(p.p.m.)

		Ni	135
		Co	35

We propose that melting of Al-rich residual lower crustal material in the Proterozoic will produce dry plagioclase-rich melts, enriched in Eu, with low Rb/Sr ratios, unsupported ^{87}Sr/^{86}Sr ratios (inherited from the precursor history) and variable Sm/Nd (and ε_{Nd}) reflecting previous complex crustal history. This typically, but not exclusively, consists of (1) mantle derivation in the late Archaean; (2) extraction of granitic melts by intracrustal melting within 100–200 Myr; (3) residence time in the lower crust in a low Rb/Sr, high Sm/Nd environment for several hundred million years; and (4) a massive melting episode producing the anorthosite magma, which rises and intrudes the upper crust at ~1,500 Myr.

Ashwal and Wooden[8] attributed the ε_{Nd} range between −6.1 and +4.1 for Proterozoic anorthosites from the Nain and Grenville Provinces to derivation from distinct mantle source regions, one enriched (Nain Province) and the other depleted (Grenville Province) in light REE (LREE). A lower crustal origin, however, is more compatible with these data. This is illustrated in Fig. 2 where the evolution of ε_{Nd} values with time is shown for the upper, lower and bulk crustal compositions given in ref. 12. In 500 Myr, ε_{Nd} of the lower crust decreases by two units, while the upper crust decreases by six units. Thus material can reside in the lower crust for extended periods (500 Myr) with only slight decreases in ε_{Nd}, even if a period of 100–200 Myr is allowed following mantle extraction before intra-crustal differentiation occurs. Thus the Nain Province anorthosites considered by Ashwal and Wooden[8] to come from enriched mantle may instead represent melts of older (500 Myr) lower crustal precursors. We note that the Adirondack anorthosites which have highly positive ε_{Nd} (+4) imply derivation from sources more highly depleted in LREE, or from regions with a shorter (<300 Myr) lower crustal residence time. This correlation between crustal provinces and anorthosite Nd isotopic characteristics is consistent with our model, but becomes coincidental if anorthosites are derived from the mantle.

The initial $^{87}Sr/^{86}Sr$ ratios of anorthosites do not directly constrain the crustal prehistory, as anorthosites are characterized by exceedingly low Rb/Sr ratios. The typical $^{87}Rb/^{86}Sr$ ratio (0.03) resembles that of MORB sources and hence the evolution of $^{87}Sr/^{86}Sr$ in the anorthosite source cannot readily be distinguished from that of the mantle. However, the initial Sr ratios for many anorthosites lie in the range 0.7026–0.7066 (ref. 8). The higher values are significantly greater than that expected from a direct mantle origin. This has been attributed to interaction with metasedimentary material or metamorphic fluids. An equally plausible scenario is that the anorthosite protolith existed for a limited period (100–200 Myr) with higher Rb/Sr ratios ($^{87}Rb/^{86}Sr \approx 1$). In our model, this represents the period of crustal residence following mantle extraction, but before intra-crustal differentiation into a granitic upper crust and an Rb depleted lower crust.

Although this postulated sequence of events seems capable of explaining the geological, petrological, geochemical and isotopic characteristics of massif anorthosites, the source of heat required to produce massive lower crustal melting is a major problem. Two heat sources are available for melting continental crust: (1) heat released by the decay of radioactive elements within the crust; and (2) heat released from the underlying mantle and conducted through the crust. The low Rb/Sr ratio of anorthosites indicates that the parent magmas were generated from a source depleted in Rb and other incompatible elements including the heat-producing elements K, U and Th. Most concepts of crustal differentiation, including intracrustal melting and fluid migration models, similarly predict low abundances of the heat producing elements in the lower crust. We suggest that these elements were effectively removed by earlier intracrustal melting episodes which produced the granitic upper crust, and concentrated the bulk of the crustal complement of K, U and Th in the upper 10 km of the continental crust.

Accordingly, it is necessary to invoke a mantle source of heat to generate the anorthositic magmas. Such a heat source must be extensive, linear (to account for the observed geological distribution[3]), operate on a time scale of up to several hundred million years and be capable of heating the base of the crust to temperatures in excess of 1,300 °C. The temperature of basaltic magmas extruded at the surface of the Earth rarely exceeds 1,250 °C, but it has been shown[18,19] that volcanic magmas occupy a density minimum in a tholeiitic fractionation trend with the suggestion that both the crust and crustal magma chambers act as a density filter, preventing dense, primitive magmas from reaching the surface. Parent magmas for mid-ocean ridge basalts (MORB) probably had MgO contents of ~18% (refs 20–22), and liquidus temperatures around 1,400 °C (ref. 23). If a continent migrates over a mantle line plume of the mid-ocean ridge type, then temperatures in excess of 1,400 °C are likely for the upper mantle adjacent to the base of the crust. If such a plume persisted for an extended period of time, as required by our model, temperatures in excess of 1,300 °C do not seem unreasonable for the base of the crust.

Our assessment of the available data reveals that a lower crustal origin for massif-type anorthosites is plausible. On the other hand, if anorthosites can be shown to be derived from mantle sources, then these must have many of the isotopic and chemical characteristics of our lower crustal models. This implies that the magnitude of mantle isotopic and chemical heterogeneity is very much greater than presently recognized.

Role of paternal and maternal genomes in mouse development

Sheila C. Barton, M. A. H. Surani* & M. L. Norris

AFRC Institute of Animal Physiology, 307 Huntingdon Road,
Cambridge CB3 0JQ, UK

There has been much speculation on whether mammalian eggs with two male pronuclei can develop normally. Eggs with two female pronuclei can sometimes develop as far as the 25-somite stage[1–3] but with only very meagre extraembryonic tissues[2,3]. We suggested that the genome undergoes specific imprinting during gametogenesis[3] and that some paternal genes may be necessary for normal development of the extraembryonic tissues[3,4], in which only the maternal X chromosome remains active[5–9]. However, the need for the maternal genome for development to term is not yet unequivocally established. The detailed study described here demonstrates that while between 40 and 50% of heterozygous reconstituted eggs with a male and a female pronucleus develop to term, none of the eggs with two male pronuclei does so. Furthermore, embryos in the latter case are very retarded, even though the trophoblast develops relatively well compared with embryos having two female pronuclei[1–3]. Our combined results indicate that while the paternal genome is essential for the normal development of extraembryonic tissues, the maternal genome may be essential for some stages of embryogenesis.

Fertilized eggs were obtained from (C57BL/6J × CBA/Ca) F_1 females (henceforth called F_1) mated with MF1 albino outbred males or from MF1 ♀ × F_1 ♂ pairings. The female pronucleus was removed from the recipient eggs (usually from F_1 ♀ × MF1 ♂) and replaced with a male pronucleus from MF1 ♀ × F_1 ♂ to yield MF1 ♂ + F_1 ♂ androgenetic eggs. In a small series, F_1 ♂ + F_1 ♂ (MF1 recipient egg) or MF1 ♂ + MF1 ♂ (F_1 donor and recipient eggs) were also prepared. As a control for these experiments, the male MF1 pronucleus from F_1 ♀ × MF1 ♂ eggs was removed and replaced with another F_1 male pronucleus from MF1 ♀ × F_1 ♂ eggs, or the female F_1 pronucleus was removed from F_1 ♀ × MF1 ♂ eggs and replaced with another MF1 female pronucleus from MF1 ♀ × F_1 ♂ eggs (see Table 1). All the reconstituted eggs with two pronuclei were cultured overnight, when the majority of them cleaved to the two-cell stage. These embryos were transferred to the right oviducts and the control MF1 × MF1 eggs (except in the case of the MF1 ♂ + MF1 ♂ experimental eggs, when F_1 ♀ × F_1 ♂ eggs served as controls) to the left oviducts of day 1 pseudopregnant mice (day 1 = day of vaginal plug).

The results (Table 1) demonstrate that 28 androgenetic eggs implanted (23%), and eight of these contained very retarded embryos (4–6 somites) or embryonic remains when examined on day 10 or 11 of pregnancy. All the embryos showed substantially better development of extraembryonic membranes and trophoblast compared with the embryo itself (see Fig. 1 for a description of all the embryos obtained). Poor development of androgenetic embryos cannot be attributed to manipulation of the egg because, in the first series of experiments, three reconstituted eggs out of five containing a male and female pronucleus, developed normally to produce embryos with between 25 and

Fertilized eggs, F_1 ♀ × MF1 ♂ and MF1 ♀ × F_1 ♂, were recovered 16–21 h after an injection of 5 IU human chorionic gonadotropin (HCG) in animals which had been injected previously with 5 IU pregnant mare's serum (48 h before injection of HCG) to induce superovulation. The cumulus cells were dispersed by incubation in 300 IU ml^{-1} hyaluronidase (ovine testis; Sigma) in phosphate-buffered medium (PBI)[20] +0.4% bovine serum albumin (BSA) for 3–5 min at 37 °C. Eggs were then washed 6–9 times in M16[21] +0.4% BSA and cultured in this medium under paraffin oil at 37 °C in humidified 5% CO_2 in air. Micromanipulation of eggs was done on a Leitz micromanipulator as described previously[2]. The donor and recipient eggs (10–15 of each) were placed in PBI +0.1% BSA containing the cytoskeletal inhibitors cytochalasin D and Nocodazole (Sigma) at a final concentration of 1 $\mu\text{g ml}^{-1}$ and 0.05 $\mu\text{g ml}^{-1}$ respectively, dissolved in 1.5 µl dimethyl sulphoxide[2]. After 30–45 min at 37 °C, the eggs were suspended in hanging drops for micromanipulation. One of the pronuclei was first removed from all the recipient eggs with a 25 µm bevelled needle using the technique described by McGrath and Solter[22], to prepare haploid recipient eggs. Using the same needle, a pronucleus from donor eggs was drawn into the needle and the membrane pinched off to make a small karyoplast fragment[22], followed by approximately 6 pl of β-propiolactone-inactivated Sendai virus[23,24] (3,000 haemagglutination units ml^{-1}) to induce fusion[25]. Virus and karyoplast were then gently released into the perivitelline space underneath the zona pellucida of the recipient egg[22]. The procedure was repeated for each recipient egg. The recipient eggs with adhering karyoplasts were washed twice in PBI +0.1% BSA and cultured in M16 +0.4% BSA at 37 °C as described above. The eggs were checked for fusion of the karyoplast ~4 h after the completion of manipulation on the last group of eggs. Fusion was confirmed by the disappearance of the karyoplast and the appearance of two pronuclei within the recipient egg. The fusion rate was 80–100%. The diploid reconstituted eggs were separated, washed nine times in equilibrated M16 +0.4% BSA and cultured overnight in this medium at 37 °C in 5% CO_2 in air under paraffin oil. The following morning, 98% of the eggs had cleaved and these were transferred to the oviducts of day 1 MF1, CFLP or F_1 pseudopregnant mice which were obtained by mating with vasectomized males of proven sterility.

* The F_1 animals are non-albino homozygous for glucose phosphate isomerase, GPI-*bb*, while the MF1 are outbred albino, GPI-*aa*.

† Ak, androgenetic; Gk, gynogenetic.

‡ Androgenetic embryos were examined on day 10 of pregnancy (groups 1–4) while the reconstituted eggs with a male and a female pronucleus were allowed to proceed to day 19 (group 5) when live young were obtained by autopsy. The embryos were typed for GPI[26] and confirmed as GPI-*ab* (group 1), GPI-*aa* (group 2), GPI-*bb* (group 5) and GPI-*aa* (group 6).

§ Twenty-two females and 13 males were obtained by autopsy on day 19 of pregnancy.

‖ Thirteen females and 14 males were obtained by natural birth. All live young from groups 5 and 6 have reached adulthood and bred normally.

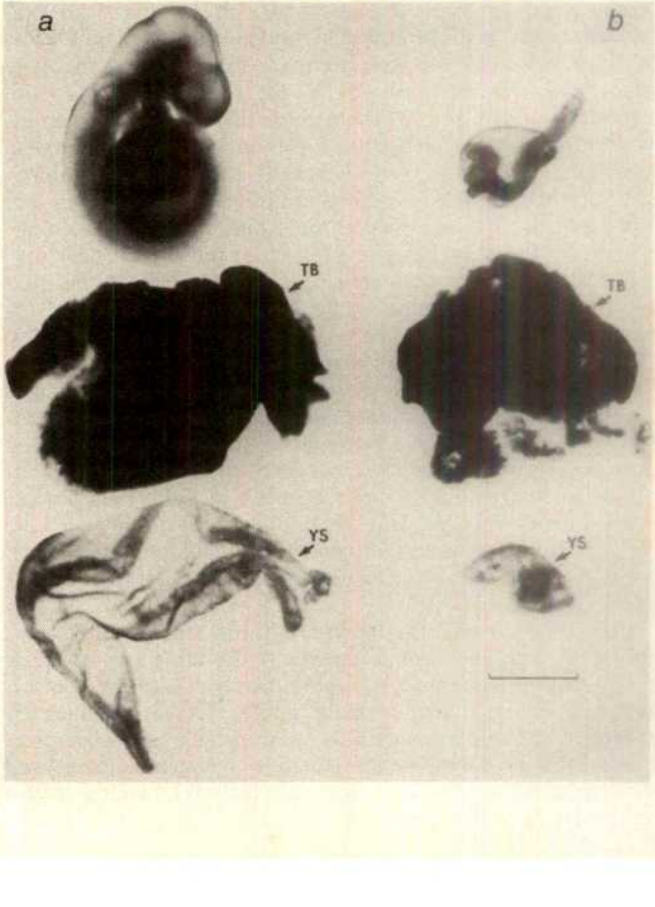

Fig. 1 Normal control embryo (*a*) and androgenetic embryo (*b*) from the same recipient on day 10 of pregnancy, each with its trophoblast (TB) and yolk sac (YS). The retarded androgenetic embryo has ~5 somites and is well formed but rather small for its stage; the trophoblast apparently is normal. The control embryo is at the 25-somite stage (scale bar 1.0 mm). Of the androgenetic embryos transferred, 23% implanted and a quarter of the decidua contained embryos or embryonic tissue at day 10. The decidua were uniformly smaller than those of the concurrent normal controls, whether or not embryos were present. Where embryos were present there was a substantial amount of trophoblastic tissue (giant cells and ectoplacental cone), and the yolk sac was substantial and expanded considering that the embryos were very retarded, unlike embryos from eggs with two female pronuclei[1-3]. Of the embryos present, four had reached the 4–6-somite stage (one of these was examined on day 11 and showed no signs of further development; tissue thickening and the onset of deterioration was evident). The fifth embryo had no somites but was rather large for a headfold embryo. A sixth embryo consisted of substantial but poorly organized neural tissue and somites, and a seventh had ~10 somites from the beating heart downwards, but had no head. One deciduum contained a tiny yolk sac vesicle inside a solid lump of trophoblastic tissue. There were no detectable embryonic remains in the rest of the 20 decidua. The three reconstituted control embryos analysed on day 10 were 25–35-somite embryos of normal size and in normal size decidua, indistinguishable from unoperated controls.

35 somites. The remainder of these normal reconstituted eggs were allowed to proceed to term, when 62 live young (43%) were obtained on day 19 of pregnancy (Table 1).

This study demonstrates that heterozygous androgenetic embryos are unlikely to develop to term. Three different types of androgenetic embryos would be expected, nearly 25% of them containing two Y chromosomes and dying within a few cleavage divisions[8], 25% XX, and 50% XY. It is unknown which of the last two categories of embryos develops better. The maternal X chromosome is preferentially active in the extraembryonic tissue whereas X-inactivation is random in the embryonic ectoderm from which the fetus develops[5–7]; this may partly influence development of androgenetic embryos. In our previous study, homozygous androgenetic embryos (which are YY or XX) had an exceptionally low implantation rate (6%) and no embryonic derivatives were detected[2]. Our results contrast with the reported birth of two homozygous androgenetic females[9], but this and similar findings[9,10] have not yet been substantiated[2,3,11–13]. The embryos with two male pronuclei in this study differ from those with two female pronuclei[2,3], especially with respect to better development of the trophoblast in the former but a better embryo in the latter. There is, however, no consistent development of the experimental embryos. This could be partly due to the necessary interactions between embryonic and extraembryonic tissues[14], which may be impaired to a varying extent.

We have recently suggested that the presence of a male and a female pronucleus is usually necessary for development to term and that this is probably because the paternal and the maternal genomes undergo specific imprinting as a result of epigenetic influences during gametogenesis[3]. There is some evidence to suggest that the differences between the paternal and the maternal genomes are recognized and may be used in embryogenesis. The nonrandom activity of the maternal X chromosome in the extraembryonic tissues is an example of such recognition[5–7]. Furthermore, specific paternal genes may also be necessary for the normal development of the trophoblast, as shown by studies on DDK mutant mice[4]. The absence of a paternal genome in an egg does result in the poor development of extraembryonic tissues[2,3], for example, both triploid and dygynic embryos develop poorly but the latter in addition have meagre extraembryonic tissues, which is attributed to the removal of the male pronucleus[2]. By contrast, we show here that eggs with two male pronuclei have substantial trophoblast but a very retarded embryo. In the human, androgenetic embryos (both XX and XY) sometimes display development as hydatidiform moles which consist of abundant chorionic vesicles and trophoblast, but the fetus is usually absent[15]. Furthermore, studies on the T^{hp}-deletion mutation of chromosome 17 in the mouse suggest that a normal chromosome 17 in the maternal, but not the paternal, genome is essential for normal development[16–18]. Hence, reconstituted eggs lacking entirely the maternal genome, as in this study, would not be expected to complete embryogenesis.

Our studies suggest that eggs with either the paternal or maternal genomes can only develop up to the blastocyst stage; some of these embryos implant and develop to a varying extent partly depending on the genotype. We suggest that the differences in the paternal and maternal genomes are recognized and may be important during embryogenesis in the establishment of the primary lineages. How these differences are involved in the interactions between the paternal and maternal genomes[12] and in gene expression during development remains to be determined.

After submission of this paper, results of a similar study were reported[19], with conclusions essentially the same as ours (refs 2, 3 and the present study); approximately 5% of the control reconstituted eggs with a male and a female pronucleus developed to term but none of the androgenetic or gynogenetic embryos did so. Two post-implantation gynogenetic embryos, one of them with 11 somites, were detected but no androgenetic embryos were obtained.

A biological consequence of variation in the site of D–J_H gene rearrangement

One mechanism which generates diversity in immunoglobulin variable (V) regions is flexibility in the site of recombination among the constituent genetic elements[1–7]. Within a specific antibody family (that is, a particular V_H–V_L combination), variability in *V–D–J* rearrangement not only leads to sequence diversity at the boundary of the juxtaposed genes, but also enables the total length of the third complementarity-determining region (CDR-3) of the heavy chain to be conserved[8]. We demonstrate here that the junctional diversity inherent in rearranged immunoglobulin genes can have consequences for the biology of the immune system. Sequence analysis of the expressed immunoglobulin genes of idiotypically variant as opposed to conventional B lymphocytes of a dominant antibody family showed that the variant B cells undergo a novel D–J_H joining event such that an extra amino acid is inserted into the heavy chain CDR-3. The unique D-region conformation possessed by the variant B cells accounts for previous observations which showed that variant and conventional B cells could be differentially regulated *in vivo* by an autologous set of idiotope-specific B lymphocytes[9]. Our findings indicate that D-region structure can determine the expression of regulatory idiotopes and suggest that the conservation of heavy-chain CDR-3 length within an antibody family may reflect regulatory as well as functional constraints.

Serological studies using monoclonal anti-idiotype antibodies and sequence analysis of monoclonal immunoglobulins have shown that there is a significant degree of structural diversity among BALB/c anti-phosphorylcholine (anti-PC) antibodies belonging to the dominant T15 idiotype antibody family[10–12]. Using the A/J anti-T15 monoclonal antibodies AB1-2 and GB4-10, a minor subset of T15$^+$ anti-PC IgM antibodies can be detected in BALB/c mice which do not express the latter idiotope (constituting 0–3% of the normal *in vivo* anti-PC IgM response[10]). The biological significance of this particular idiotypic heterogeneity became apparent when an *in vivo* B-cell counterpart to the GB4-10 anti-T15 hybridoma was found in

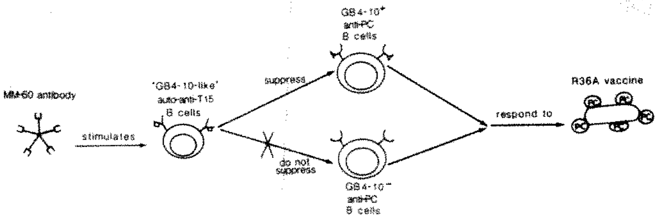

Fig. 1 Schematic diagram of a monoclonal model for idiotype-directed regulation of immunoglobulin production. *In vivo* administration of the auto-anti-(anti-T15) monoclonal antibody, MM-60 (ref. 13) induces proliferation among a restricted, possibly clonal, set of auto-anti-T15 B cells possessing a specificity identical to the A/J anti-T15 hybridoma GB4-10 (ref. 9). Once stimulated, 'GB4-10-like' anti-T15 B cells suppress anti-PC IgM production from only those B cells bearing the GB4–10-defined idiotope; anti-PC IgM production by GB4–10⁻ B cells is unimpaired. The anti-PC humoral response of BALB/c mice is dominated by the GB4-10⁺ component, with 95–100% of all anti-PC serum IgM bearing the GB4–10-defined idiotope[10]. All GB4–10⁺ anti-PC antibodies are also T15⁺, while 40% of GB4–10⁻ anti-PC IgM antibodies in primary immune response are T15⁺ (that is, the variant population studied here), the remainder belonging to the M511 and M603 idiotypic families[10,34].

BALB/c mice and was shown to specifically suppress the production of anti-PC IgM from B cells bearing the GB4-10-defined idiotope[9]. Figure 1 summarizes, from previous work[9,13], the cellular and humoral interactions involved in this differential regulation of the primary *in vivo* B-cell response to PC and how it approximates to a monoclonal model for autologous idiotype-directed immunoregulatory processes. Determining the structural correlate of the GB4-10-defined idiotope would indicate which region(s) of the immunoglobulin molecule are responsible for the expression of regulatory idiotopes and also what genetic changes lead to the loss of such idiotopes, thereby permitting a B lymphocyte to avoid regulation.

To achieve this, four B-cell hybridomas secreting a monoclonal anti-PC IgM of the T15⁺ GB4-10⁻ phenotype (designated 2-21, 5-18, 7-22 & 12-3) were identified following fusion of the nonproductive plasmacytoma Ag8.653 (ref. 14) to spleen cells from BALB/c mice undergoing a primary immune response to R36A pneumococcal vaccine. The monoclonal antibodies from all four variant hybridomas bind PC–protein conjugates and R36A bacterial cells; the purified IgM from the variant 12-3 hybridoma appears to bind PC with an affinity comparable with that of BH8, a monoclonal T15⁺ GB4-10⁺ anti-PC IgM of germ-line sequence (B. A. P., unpublished observation). To prove that those hybridomas from the same fusion (2-21, 5-18, 7-22) were the immortalized products of distinct B-cell clones, the nonproductively rearranged heavy-chain gene of each hybridoma was examined by Southern blot analysis using a J_H region-specific probe[15]. Each hybridoma possessed a different sized J_H-containing *Eco*RI restriction fragment from its nonproductive allele, demonstrating that each hybridoma was derived from independent anti-PC B-cell precursors (data not shown). In addition, no gross structural differences in the T15 V_H–J_H1 gene complex were detected between the variant hybridomas and the prototypic T15⁺ anti-PC plasmacytoma S107 (heavy- and light-chain genes of germ-line sequence[16,17]) as shown by the presence of a 7.5-kilobase (kb) J_H-containing *Eco*RI fragment[5] in all cases.

Loss of expression of GB4-10-defined idiotope could be due to subtle alterations in light- and/or heavy-chain structure as both T15 V_L and V_H regions contribute to idiotope expressions[9,10]. Examination of light-chain structure by isoelectric focusing showed that purified κ light chains from two variant hybridomas (5–18, 7–22) co-migrated with the secreted κ chain of S107 (*p*I 8.0) (ref. 9). The germ-line character of the light chains produced by GB4-10⁻ variant B cells was confirmed by sequencing portions of the κ-chain mRNA from the hybridomas 12–3 and 5–18 (see Fig. 2 legend); the κ mRNA sequence from both variant hybridomas was identical to the S107A κ gene[17] from the beginning of CDR-2 (codon 50) to $J_\kappa1$ (codon 108) (data not shown). The presence of mutations upstream of CDR-2 in the T15 V_L gene of the variant is highly unlikely as somatic mutation in the expressed light-chain genes of IgM-producing B cells (as seen in representative hybridomas) is rare[12,18,19]. In support of this, experiments using recombinant immunoglobulin molecules from GB4–10⁺ and GB4–10⁻ T15⁺ anti-PC hybridomas confirm that expression of the GB4–10-defined idiotope in the T15 family is associated with the heavy chain[9]. Hence, alterations in the T15 V_L structure do not appear to be the basis for the absence of expression of this regulatory idiotope.

Fig. 2 Nucleotide sequence of the V_H–$5'C_\mu$ region for several idiotypically variant and conventional T15⁺BALB/c monoclonal anti-PC immunoglobulins. The heavy-chain sequence of the S107 plasmacytoma[5] serves as the prototypic sequence for BALB/c anti-PC antibodies as it expresses the germ-line T15 V_H, *D*FL16.1 and J_H1 gene sequences in rearranged form[5,19]. The IgM constant-region gene sequence[35] replaces the IgA constant region in the S107 prototypic sequence as all the immunoglobulins studied here are of the IgM class. Undetermined bases (sequence ambiguities) are denoted by dashes and reactivity with the anti-T15 idiotope antibody GB4–10 is shown as (+) or (−). Sequencing of the hybridoma heavy-chain mRNA was performed as described by Caton *et al.*[36]. A 17-base synthetic oligonucleotide primer complementary to the 5′ end of the first exon of the μ heavy-chain constant gene (underlined nucleotides) was used to initiate reverse transcription of poly(A)⁺ cytoplasmic RNA. Specific dideoxynucleotides were included in the reaction mixtures to create base-specific stops during cDNA synthesis with [$\alpha-{}^{32}$P]dATP or [$\alpha-{}^{35}$S]dATP as the incorporated label. The nucleotide sequence of the cDNA was determined by electrophoresing the labelled cDNA fragments on polyacrylamide gels, followed by autoradiography of the gel. The first 10 bases distal to the primer were consistently indiscernible and the maximum sequence length accurately readable by this method was approximately 250 bases, which permitted sequencing of the entire CDR-2. The confirmatory heavy-chain sequence of the T15⁺ GB4-10⁺ anti-PC IgM-secreting BALB/c hybridoma BH8 (ref. 10) eliminates the possibility that the insertion of the TAC codon at the D–J_H junction is an artefact of our procedure for sequencing μ heavy chains.

Fig. 3 Pattern of D–J_H gene rearrangement in GB4–10$^+$ versus GB4–10$^-$ anti-PC B-cell precursors. Rearrangement between the *D*FL16.1 and J_H1 genes could occur at five and two alternate sites in GB4–10$^+$ nonvariant and GB4–10$^-$ variant anti-PC immunoglobulins, respectively (designated by arrows); the two D–J_H joining positions for GB4–10$^-$ variant antibodies are distinct from all the possible sites used by the GB4–10$^+$ nonvariant group. The boxes show the conserved heptamer recognition sequences defined by Sakano *et al.*[7]. The J_H1 and *D*FL16.1 gene sequences have been described previously[5–7,20].

The primary structure of the heavy chain expressed by each variant and a nonvariant hybridoma was examined by sequencing the μ heavy-chain mRNA in the same way (Fig. 2). The heavy chains of all the variant hybridomas are coded by T15 V_H (ref. 6), DFL16.1 (ref. 20) and J_H1 (ref. 5); the same V_H, D and J_H genes as the two nonvariant heavy chains. The heavy-chain gene sequences of the variants are also identical with the germ-line (that is, unmutated) sequence of the constituent T15 V_H, *D*FL16.1 and J_H1 genes (for codons 50–113). The only notable difference in heavy-chain gene structure exhibited by the variant group is the presence of an extra tyrosine codon (TAC) at the D–J_H gene junction. That this structural peculiarity is the sole basis for loss of the GB4–10 regulatory idiotope is strengthened by the finding that amino acid substitutions present throughout V_H of T15$^+$ anti-PC antibodies (including those in regions not sequenced here, such as in CDR-1) have no effect on idiotope expression (ref. 9 and B.P., unpublished data).

Examination of the nucleotide sequence at the 3′ end of the germ-line *D*FL16.1 gene[20] indicates how this insertion might occur (Fig. 3). Although the site of D–J_H joining cannot be precisely defined for either the conventional or the variant T15$^+$ antibody group, generation of the two distinct heavy chains is clearly dependent on different D–J_H gene recombinations. Considering the consistency in length and composition of this site, it is highly unlikely that it derives from an 'N segment'—the non-templated, G+C-rich region often present at the D–J_H boundary[21]. Detection of functional variants within the virgin anti-PC B-cell repertoire of neonatal mice by the clonal splenic focus assay[22,23] (B. A. P. and M. V., unpublished observations), is consistent with the molecular evidence showing that generation of these variant B cells is determined at an early stage of B-cell ontogeny. Although insertion of an extra codon at the site of recombination among immunoglobulin genes is not a rare occurrence, the heavy-chain gene structure of the T15$^+$ GB4–10$^-$ B cells is unusual because the insertion here is not accompanied by a compensating deletion of a codon at the V_H–D junction; this results in a heavy-chain CDR-3 longer by one amino acid residue than the CDR-3 length of all other sequenced T15$^+$ antibodies.

Consistency in heavy-chain CDR-3 length is not unique to the T15 antibody family, but is an apparently universal characteristic among antibody families which dominate a particular antigen response; paucicional systems which exhibit this trait include the anti-α-1, 3 dextran[24], anti-galactan[25], anti-inulin[26], anti-'GAT'[27,28] and anti-phenyloxazalone responses[29]. Although conservation of a particular CDR-3 conformation would most reasonably be based on some functional criterion such as antigen binding activity or light-chain pairing potential, this may not necessarily be the case. Variation in CDR-3 primary structure due to utilization of different D genes and/or flexibility in V_H–D–J_H joining apparently alters neither the antigen specificity nor the ability to pair with the respective light chain for anti-dextran, anti-galactan and anti-PC antibodies[8]. In addition, consistency in CDR-3 length for conventional T15$^+$ anti-PC antibodies cannot be due to a highly preferential V–D–J recombination which precludes all others, as several anti-PC antibodies containing non-T15 light chains and heavy chains coded for by the T15 V_H, *D*FL16.1 and J_H1 genes do exhibit different CDR-3 lengths[12]. Our results indicate that deviation from uniformity in CDR-3 length does not necessarily affect antigen binding or light-chain pairing, but can lead to destruction of a regulatory idiotope and possibly, to the creation of a regulatory idiotope(s) unique to CDR-3 length variants. Conservation of a particular CDR-3 length within a dominant antibody family may be necessary to ensure that target idiotopes responsible for the coordinated regulation of an immune response are properly displayed to the surrounding milieu. The validity of such a model is supported by studies on tertiary structure of V regions of monoclonal anti-PC[30] and anti-galactan[31] antibodies which show that D-region residues are prominently exposed on the external surfaces of the immunoglobulin molecule. Regularity in heavy-chain CDR-3 length within an antibody family may thus reflect a B lymphocyte's niche in the idiotypic network rather than being due solely to antigen binding or light-chain pairing.

It is intriguing that most of the family-specific idiotopes defined so far on mouse immunoglobulins using mouse anti-idiotypic antibodies have been mapped to the D regions[25,32,33]. However, a model of idiotype-specific immunoregulation based on recognition of D-region-determined idiotopes presumably necessitates the existence of an extensive number of anti-idiotypic elements considering the degree of D-region sequence variability often present within an antibody family[25]. Our studies on the 'mini-network' described here suggest an alternative model; the expression of a D-region-determined regulatory idiotope can be resistant to many of the sequence substitutions in a given D-region (ref. 9 and B.P., unpublished data), with loss of idiotope expression brought about by only a few, significant perturbations in D-region tertiary structure (for example, insertion of a bulky, non-polar amino acid at the D–J_H junction). Examination of other autologous idiotype-specific immunoregulatory systems which function *in vivo* should help to resolve whether expression of regulatory idiotopes are generally determined by D-region/CDR-3 conformation.

We thank Dr S. Clarke for instruction on RNA sequencing by primer extension, and Dr M. Weigert for providing the C_μ primer and for valuable discussions. The late blood stages of the human malaria parasite, *Plasmodium falciparum*, carry a major surface antigen, p190, of molecular weight (M_r) 190,000 (ref. 1). This antigenically variable protein[1–3] is actively processed, first as the parasite matures and again when it is released into the blood stream and invades a new erythrocyte to initiate a cycle of growth[1]. It elicits a strong immune response in man; all tested adult sera from endemic areas have antibodies against this protein[1]. Our evidence indicates that purified p190 can alter the course of parasitaemia in monkeys with falciparum malaria. We have also succeeded in cloning part of the gene for p190 and expressing it in *Escherichia coli*. To this end we have developed a new technique, antibody select, which greatly simplifies final identification of expressing clones.

The protein p190 was first defined[2] and later purified[1] by monoclonal antibodies. It begins to be made in schizogony as a 190,000 M_r protein. Processing creates smaller peptides, notably major species of approximately 160,000, 125,000, 106,000 and 82,000 M_r (ref. 1 and R.H., unpublished). These and other features strongly suggest that p190 is related to the 195,000 M_r protein studied by Holder and Freeman[4], and to similar proteins in rodent[5–7] and simian[8,9] parasites. One part of p190, defined by monoclonal antibody 2.2, is present in all isolates of *P. falciparum* tested; another part, defined by antibody 7.3, is present in p190 purified from the Thai isolate Kl (ref. 10) but absent from some other isolates[2,3]. Genetically pure lines from a single Thai patient vary in this part of the protein[11]. The antigenically variable part of the protein is cleaved off during release and re-invasion, whilst the constant part survives into the next cycle[1].

Preliminary studies suggest that p190 can protect monkeys against falciparum malaria. Immunization with the affinity-purified native protein modifies the course of infection by the parasite. We treated four control monkeys (Fig. 1) with Freund's complete adjuvant for the first immunization only and with incomplete adjuvant for subsequent immunizations before challenge with the parasite. All show a rapid rise in parasitaemia to the level (20%) at which drug treatment is given to prevent death of the animals. By contrast, two of the three immunized monkeys after an initial rise, rapidly lose detectable parasites and recover. All the immunized monkeys develop antibodies against p190 and show an anamnestic response after challenge (Table 1). Interestingly, the variable part of the p190 protein used in this experiment (purified from isolate K1), was different from its homologue in the challenge parasite (Palo Alto strain)[2,3]. This suggests that the constant part of p190 may have protective value.

Table 1 Antibody response to p190 immunization

Monkey	Inoculated with:	Antibodies against p190 (reciprocal titres) *a*	*b*	*c*
Sven	FCA	<100	<100	100
Uli	FCA	<100	<100	100
Dora	FCA	<100	<100	900
Ronnie	FCA	<100	100	100
Laura	p190+FCA	<100	24,300	>72,900
Anita	p190+FCA	100	8,100	>72,900
Hugo	p190+FCA	<100	24,300	>72,900

Anti-p190 antibodies assayed by ELISA in the treated monkeys. *a*, Before immunization; *b*, after immunization; *c*, 30 days after challenge. FCA, Freund's complete adjuvant. Microtitre plates (Nunc) were coated with affinity-purified p190: 50 μl containing ~100 ng were added to each well and incubated (room temperature; overnight), washed thoroughly (×5) with tap water. Remaining sites were blocked with 100 μl of bovine serum albumin (BSA) solution (3% in phosphate-buffered saline, PBS) for 30 min (room temperature). Threefold dilutions (50 μl) of monkey sera (in 1% BSA in PBS) were incubated (room temperature; 6 h) in each well; the plate was washed (tap water) before adding urease-conjugated rabbit anti-Saimiri IgG antiserum (50 μl of an appropriate dilution in 1% BSA (as above), overnight at room temperature and washed again (×4 in tap water ×2 in distilled water). 150 μl of urease substrate (urea, 0.1%; 0.008% bromocresol purple; 0.2 mM EDTA; *p*H 4.8) was added to each well and incubated (37 °C, 45 min). A positive reaction registers as a change from purple to yellow[27].

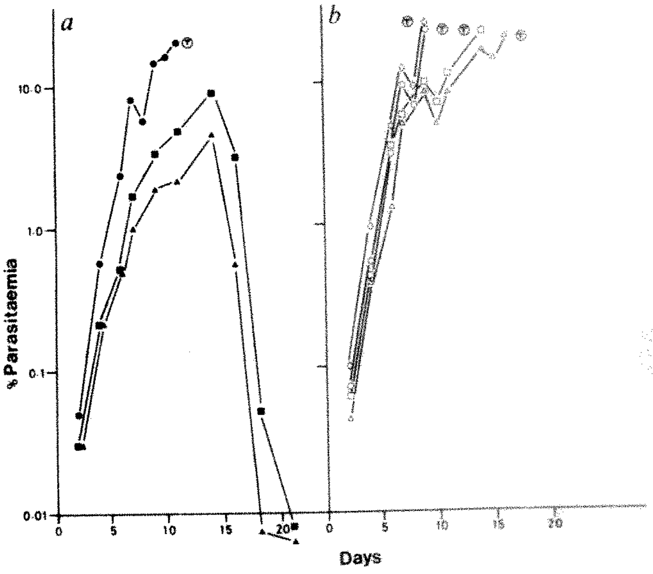

Fig. 1 Effect of p190 on the course of parasitaemia in Saimiri monkeys. *a*, Immunized monkeys. Affinity-purified p190 was injected into three monkeys with Freund's complete adjuvant—Anita (●), Hugo (■) and Laura (▲). Each received subcutaneously 50 μg at day −52, 50 μg at day −39 and 50 μg at day −19. *b*, Controls (open symbols) received adjuvant alone. After immunization, all the monkeys were challenged intravenously with ~2×10^7 parasitized erythrocytes (*P. falciparum*, Palo Alto strain) from a single donor monkey. Ⓣ indicates drug treatment. Parasitaemias were estimated by Giemsa-stained smears.

Much could be learned about this protein from cloning its gene. In addition, clones expressing the gene in bacteria would be a ready source of a protein which is a strong candidate for a subunit vaccine against falciparum malaria. Recently, DNA sequences encoding antigens from both *P. knowlesi*[12] and *P. falciparum*[13] have been cloned. These studies showed that clones

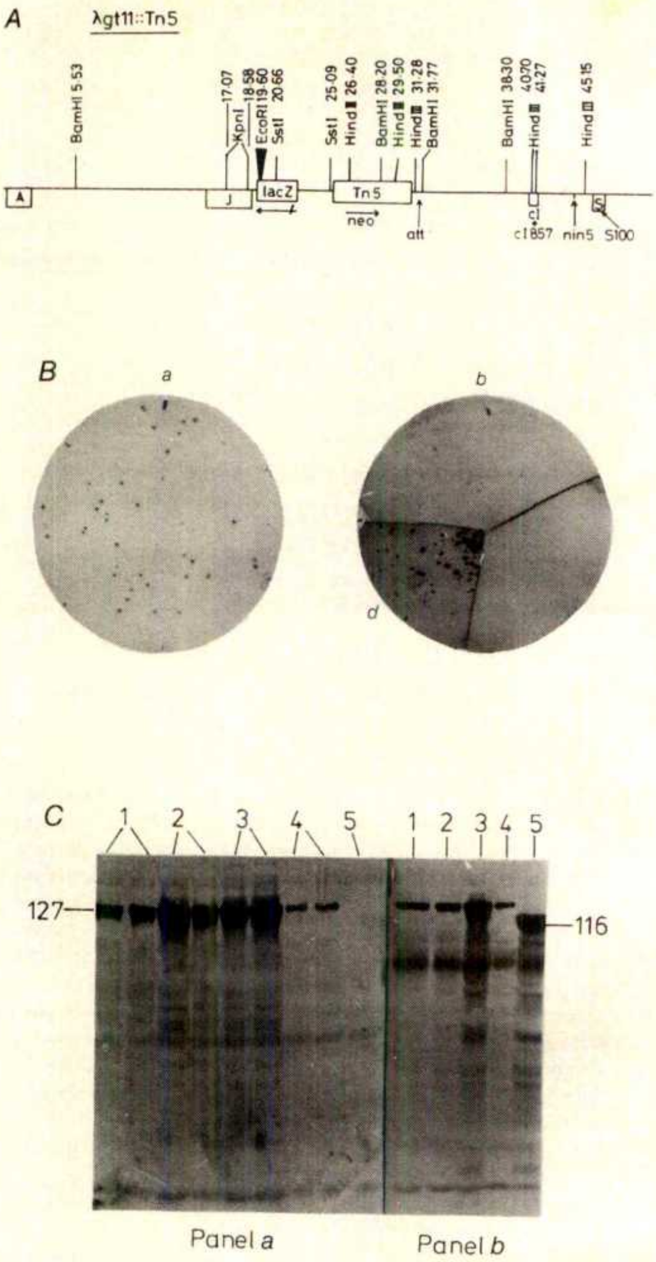

Fig. 2 Isolation of cDNA clones containing p190 sequences. *A*, Cloning vector. Phage $\lambda gt11$ :: Tn*5* was isolated following transposition of Tn*5* to $\lambda gt11$[14]. The cDNA is inserted at the unique *Eco*RI site in *lacZ*, positions of important restriction sites are indicated in kb. The phage is temperature-inducible (cI_{857}) and carries the *nin5* deletion and an amber mutation (S100) preventing lysis in the absence of a suppressor. The presence of Tn*5* greatly simplifies isolation of lysogens, as these derivatives are resistant to kanamycin. *B*, Colony screening of the $\lambda gt11$ :: Tn*5* cDNA expression library by ELISA. *a*, Positive colonies from the primary screen transferred to nitrocellulose and probed again with rabbit anti-p190 serum. *b*, p190 negative colonies from the primary screen probed with anti-p190 serum. *c*, Positive colonies from the primary screen probed with non-immune rabbit serum. *d*, p190-negative colonies from the primary screen probed with anti-β-galactosidase serum. *C*, Western blots of total protein from four p190 lysogens probed with anti-p190 serum (panel *a*, lanes 1–4, each clone run in duplicate) and anti-β-galactosidase serum (panel *b*, lanes 1–4). Lane 5 in each panel shows a control lysogen carrying the vector with no cDNA insert.

Methods: The $\lambda gt11$ :: Tn*5* cDNA library in BTA282, $\Delta lac_{U169}\Delta lon$ *araD*139 str^R *thi hfl* A150 (chr :: Tn*10*) *hsd*R^-M^+ (a derivative of RY1083, see ref. 14) was grown overnight at 30 °C on L-agar with 1555 μg ml^{-1} tetracycline and 40 μg ml^{-1} kanamycin. Colonies were replicated onto nitrocellulose and incubated 2 h at 30 °C. Phage were induced by incubation at 42 °C for 90 min. Colonies were lysed by a modification of the method of Stanley[28]. Nitrocellulose disks were placed on a pad soaked in 5% SDS and heated in a 100 °C oven for 15 min. They were immersed (1 h, 20 °C) in 5% ovalbumin in 10 mM Tris-Cl, *p*H 8.0, 150 mM NaCl (5% OA/TS) containing 0.01% NaN_3, 0.2 mg ml^{-1} henylmethylsulphonyl fluoride (PMSF) and 10 μg ml^{-1} DNase I, washed twice in TS and electroeluted (1 h, 50 V) to remove SDS. The filters were further blocked in 5% OA/TS (15 min, 20 °C) and incubated overnight in rabbit anti-p190 serum diluted 1 : 150 in 5% OA/TS (5 ml). They were washed 5× in TS and incubated in 1 : 1,000 dilution of peroxidase-conjugated goat anti-rabbit IgG in 5% OA/TS (4 h, 20 °C). After a further five washes in TS, the ELISA reaction was developed[29]. The anti-p190 serum was raised in a New Zealand White rabbit against affinity-purified p190 protein[1]. It was extensively preadsorbed on induced $\lambda gt11$ :: Tn*5* lysogens of BTA282 to remove nonspecific anti-*E. coli* antibodies. Total proteins from lysogens for gel analysis were obtained as follows: Young L-broth cultures of lysogens (in BTA282), containing 15 μg ml^{-1} tetracycline and 40 μg ml^{-1} kanamycin, were induced (90 min, 42 °C), centrifuged (1,500*g*, 10 min) and the bacteria ($\sim 2 \times 10^9$) resuspended in 60 μl of 10% SDS, 0.1 mg ml^{-1} PMSF (15 min, 20 °C) and boiled (2 min). 180 μl of Laemmli[30] sample buffer containing 7% 2-mercaptoethanol was added and after further boiling, the samples were electrophoresed on 7.5% SDS-polyacrylamide gels and Western blotted essentially as described previously[29,31]. The filters were probed with antibody as above. Markers used to calibrate the gels were ferritin (220,000 M_r), phosphorylase *b* (94,000 M_r), bovine serum albumin (69,000), catalase (60,000), ovalbumin (46,000), lactate dehydrogenase (36,000) and carbonic anhydrase (30,000).

can be detected using antibody probes to screen bacteria expressing parts of the parasite protein. We report here isolation of a p190 cDNA clone detected by a similar strategy. It includes the 3′ terminus of the messenger RNA and the sequence encoding the final 70 aminoacids at the C-terminus of the protein.

We have made a useful derivative of phage $\lambda gt11$ to serve as the cloning vector for cDNA from cultured *P. falciparum* blood stages. Like its parent,[14,15] our derivative ($\lambda gt11$ :: Tn*5*) facilitates expression of cloned cDNA in *E. coli.* The transposon Tn*5* confers kanamycin resistance on lysogens, which can thus be very easily selected (M.G., N. Bone and J.S., unpublished results). The cDNA was made from total poly$(A)^+$ RNA of blood stage *P. falciparum* isolate Kl, ligated to *Eco*RI linkers and cloned[16] into the unique *Eco*RI site of the vector. The cDNA is thereby inserted into the *lacZ* gene, encoding β-galactosidase (Fig. 2*A*). In the correct frame and orientation at this site, a cDNA molecule is expressed as a hybrid protein comprising most of the β-galactosidase molecule fused to a *P. falciparum* polypeptide (the *Eco*RI site is 153 base pairs (bp) from the C-terminus of the gene)[14,17].

Recombinant phages (~7,000) were screened for synthesis of p190 peptides. Small colonies lysogenic for the phages were transferred to nitrocellulose, induced to stimulate fusion protein synthesis and probed (see Fig. 2) with a polyclonal rabbit antiserum raised against affinity-purified p190[1]. Positive candidate clones were detected by enzyme-linked immunosorbent assay (ELISA) with horseradish peroxidase-conjugated goat anti-rabbit IgG antiserum (Fig. 2*B*). Four apparently identical clones were obtained from this screening. They each encode a hybrid protein (Fig. 2*C*) significantly larger (127,000 M_r) than native β-galactosidase[15]. In Western blots (Fig. 2*C*) they can be seen to have epitopes recognized by both the anti-β-galactosidase (right panel) and the anti-p190 (left panel) probes. By contrast, control clones synthesizing native enzyme only respond to the anti-β-galactosidase probe.

To confirm that our clones encode a p190 sequence, we have developed a rapid and simple technique which we call antibody select. This method eliminates false positive clones which could register in the initial screening if, for example, the anti-p190 probe contained antibodies against other *P. falciparum* pro-

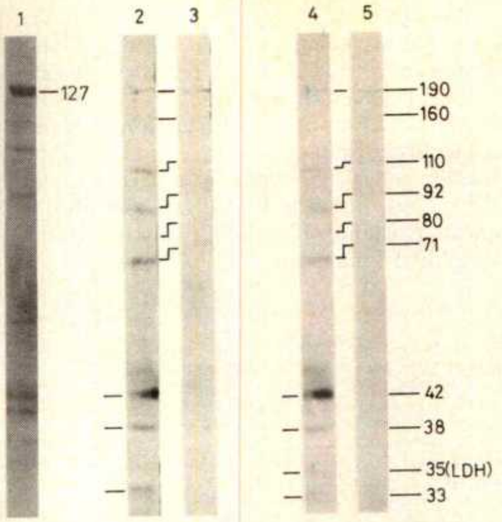

Fig. 3 Confirmation of a λp190 clone by antibody select. Lane 1, p190 hybrid protein used in antibody select (see lanes 3, 5). The protein isolated from an induced lysogen (see below) and run on an SDS-polyacrylamide gel was stained with Coomassie blue. The major band is at 127,000 M_r (see Fig. 2*C*). Lanes 2–5, Western blots of total Kl parasite proteins using the following probes: lane 2, whole anti-p190 serum; lane 3, immunoglobulins affinity-purified from the whole serum by the hybrid protein; lane 4, whole serum with added rabbit antibody against parasite lactate dehydrogenase (LDH); lane 5, immunoglobulins affinity-purified from the mixed sera of lane 4 by the hybrid protein.

Methods: p190 hybrid protein for antibody select was purified as follows: Approximately 10^{11} lysogens (in BTA282) harbouring p190-1 were grown up and collected as described in Fig. 2 legend. The bacterial pellet was resuspended in 4 ml cold 10 mM Tris-Cl, *p*H 8.0, 100 mM NaCl, 1 mM EDTA (TNE) and left on ice 5 min. 4 ml of 50% sucrose in TNE were added, followed 10 min later by 8 ml of 4 mg ml^{-1} lysozyme. After a further 15 min on ice, 4 ml of 0.25 M EDTA, *p*H 8.0 and 2 ml of 10% Nonidet P-40 were added. The suspension was freeze-thawed and the DNA sheared by 5× extrusion through a 19-gauge needle. The extract was then spun at 13,000*g*, 4 °C, 30 min and the pellet suspended in 15 ml of 8 M urea. After a further spin (13,000*g*, 4 °C, 20 min), the supernatant, which contained purified fusion protein, was retained. For antibody select, 4 ml of this supernatant was incubated with 5 cm^2 of nitrocellulose (2 h, 20 °C). After washing and blocking the filter as described for Fig. 2, it was incubated with 5 ml of undiluted rabbit anti-p190 serum plus 5 ml 5% OA/TS overnight at 20 °C. After five washes in TS, specifically bound antibodies were eluted by incubation with 2 ml of 0.1 M glycine-Cl, *p*H 2.6, 0.15 M NaCl (15 min, 20 °C). The eluted material was neutralized with 2 ml 1 M Tris-Cl *p*H 8.0 and 16 ml 5% OA/TS plus 0.01% NaN_3 were added. This solution was used to probe Western blots (lanes 3, 5). Total Kl proteins were prepared from parasite pellets (~2×10^9 mixed stage parasites) after saponin lysis of erythrocytes[1]. The pellets were boiled in 500 μl of Laemmli sample buffer and after spinning on a microfuge (5 min) 80 μl of the supernatant were run on a 7.5% SDS-polyacrylamide gel.

tein(s). Such proteins can be minor contaminants in the p190 preparation used to raise the polyclonal rabbit antiserum.

The hybrid protein of a true p190 clone should be able to bind specific anti-p190 immunoglobulin molecules, permitting them to be affinity purified from the original anti-p190 probe. By contrast, the hybrid proteins of false clones would select immunoglobulin molecules against the contaminating protein.

Hybrid protein from a candidate p190 clone (λp190-1) was bound to nitrocellulose and used to affinity-purify antibodies from the original probe (Fig. 3). The selected antibodies, when eluted and used to probe Western blots of total parasite proteins, prove to bind to p190 and its processed products (160,000, 110,000, 92,000, 80,000 and 71,000 M_r). Moreover, the selection is quite specific. When antibodies against another parasite protein (lactate dehydrogenase, M_r 35,000) were added to the anti-p190 probe, these were not selected (compare lanes 4 and

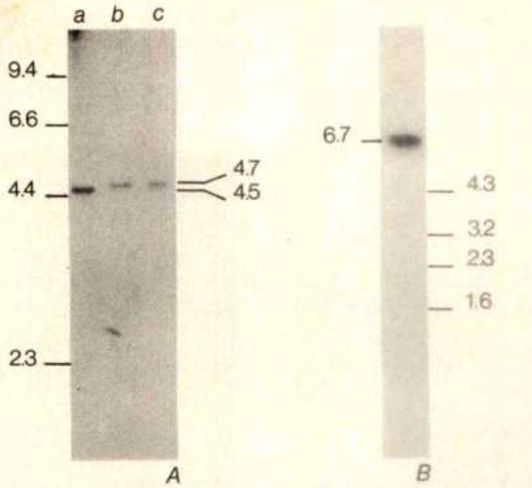

Fig. 4 Parasite sequences hybridizing to the λp190-1 cDNA insert. Panel *A*, Southern blots of *Eco*RI cleaved genomic DNA from different isolates of *P. falciparum*. Lane *a*, isolate Kl (Thailand)[10]; lane *b*, isolate MAD20 (Papua, New Guinea)[3]; lane *c*, Tak9 clone 96 (Thailand)[21]. Markers are *Hin*dIII fragments of λcI_{857} (kb). Panel *B*, Northern blot of total poly(A)$^+$ RNA from isolate Kl. Markers are *E. coli* 16S and 23S RNA and *P. falciparum* '18S' and '28S' RNA[20] (kb).

Methods: For Southern blots 6 μg of genomic DNA were cleaved with 10 U of *Eco*RI (overnight, 37 °C) and electrophoresed on a 0.7% agarose gel. For Northern blots 3 μg of poly(A)$^+$ RNA were run on a 0.8% agarose gel in 2.2 M formaldehyde[20]. Both DNA and RNA were transferred to nitrocellulose in 1 M NH_4Ac, 0.02 M NaOH (1 h). The probe was prepared by digesting λp190-1 DNA with *Kpn*I and *Sst*I to yield a 2.4 kb fragment which includes the 300 bp cDNA insert (see Fig. 2*A*). This was separated from other fragments on a preparative 0.6% agarose gel and after purification, nick-translated with [α^{32} P]dCTP to a specific activity of 1.7×10^7 c.p.m. μg^{-1}. After hybridization, filters were washed to a stringency of 0.1 ×SSC at 37 °C.

5), nor were antibodies already present in the probe against 42,000, 38,000 and 33,000 M_r contaminating proteins (compare lanes 2 and 3).

Antibody select is a rapid and convenient way to confirm or identify any foreign gene sequences expressed in bacteria. It provides an alternative to both hybrid selection of mRNA[18], which requires a large amount of mRNA from the parent organism, and immunization of mice with the fusion protein, followed by immuno-identification of the parent protein in extracts[13,19]. This latter approach is slow and we find that fusion proteins do not always elicit a strong immune response. Antibody select has the added advantage that the antibody probe used in the initial identification of the clones provides the immunoglobulins for the confirmation step. It also provides a way to purify from complex sera antibodies against defined regions of a single antigen molecule.

The clones and their hybrid protein are stable during growth in *E. coli*. Their inserts, which can all be excised with *Eco*RI, hybridize strongly to a total cDNA probe (made from blood-stage parasite poly(A)$^+$ RNA) and give an identical fragment of approximately 300 bp (data not shown). We have therefore studied one clone, representing a small fraction of the protein coding sequence in detail. We can detect the p190 message in total poly(A)$^+$ RNA extracted from mixed blood stages of the parasite. In Northern blots of denaturing gels[20] it has an apparent length of 6.7 kilobases (kb) (Fig. 4*b*), which agrees with the estimate that a coding sequence of at least 5 kb would be required for a 190,000 M_r protein.

The gene can be detected in total genomic DNA. When cut with *Eco*RI, it reveals a single major band which hybridizes strongly to the probe (Fig. 4*a*). Interestingly, when we compare DNA from three different isolates, we find a small but significant difference between Kl (4.5 kb) and two others, MAD20 and the

Fig. 5 Nucleotide sequence of λp190-1 cDNA. Sequence determination was carried out by the chain termination method[32] after subcloning *Eco*RI fragments of λp190-1 cDNA into M13mp9 (ref. 33) in both orientations. The putative polyadenylation signal is underlined. The reading frame is shown in phase with β-galactosidase. The two *Eco*RI linkers are indicated by a line above the sequence.

genetically pure clone Tak9/96 (4.7 kb). Kl and Tak9/96 are from Thailand[10,21], whilst MAD20 is from Papua, New Guinea[3]. This result may be particularly important as MAD20 and Tak9/96 differ from Kl with respect to the antigenic properties of p190[2,3].

We have estimated the frequency of the cloned p190 sequence in the *P. falciparum* DNA from the intensity of the 4.5 kb band in Southern blots of total genomic digests. Standard copy-number analysis[22,23] using the λp190-1 clone suggests that the number of copies of the p190 sequence per parasite genome is between one and five (data not shown). The part of the gene in p190-1 does not contain tandem repeats (see below and Fig. 5) as has recently been reported in coding sequences for *P. falciparum* S-antigens[13] and *P. knowlesi* circumsporozoite protein[12].

Sequencing studies (Fig. 5) in this laboratory on the p190-1 insert reveals a single open reading frame encoding 70 amino acids in phase with β-galactosidase, terminating with a UGA codon followed downstream by two other stop codons. The clone has a run of 26 A residues at its 3′ terminus. In addition, the sequence ATTAAA starts 24 bases upstream from the first terminal adenine, the expected position for a polyadenylation signal. This function has recently been attributed to the above sequence in several different systems[24-26]. We therefore suggest that the cloned sequence encodes the 3′-terminus of the p190 mRNA and the C-terminus of the polypeptide.

Our conclusion affects the interpretation of the mechanism by which p190 is processed from a primary product of 190,000 M_r to apparently smaller products. Examination of the parasite proteins reacting to the antibodies selected by the p190 clone reveals that in addition to p190, large product bands are also found (Fig. 3, lanes 3, 5). This strongly suggests that epitopes in the C-terminus are not removed by processing. The simplest interpretation of our result is that processing removes the N-terminus of the p190 polypeptide.

We have been unable to detect in the polypeptide encoded in p190-1 epitopes defined by monoclonal antibodies, including 2.2 and 7.3. This may simply reflect the fact that p190-1 contains less than a tenth of the total coding sequence. An alternative explanation is that the C-terminus of p190 cannot elicit an immune response because it is sequestered inside the parasite, as the monoclonal antibodies were obtained after immunization Hwith a whole parasite preparation[2].

The present report describes a cloned gene for a *P. falciparum* protein known to be both strongly immunogenic in man and a candidate for a subunit vaccine against malaria. We now have clones with larger p190 sequences which will test whether, HHlike the native protein (and its homologue in *P. yoelii*[5]), p190 synthesized in bacteria can elicit a protective response against blood stages of the parasite.

We thank David Finnegan, Clare Lister and Andrew Coulson for help and advice on sequencing, John Pugh, David Walliker, Jana McBride and Neil Willetts for discussions and materials, Jackie King, Neil Bone, Ines Calligari and Marija Komarica for technical assistance, Betty McCready for typing the manuscript, and MRC for support.

Human antisera detect a *Plasmodium falciparum* genomic clone encoding a nonapeptide repeat

Plasmodium falciparum causes malaria infections in its human host. Its wide distribution in tropical countries is a major world health problem. Before a vaccine can be produced, the identification and characterization of parasite antigens is necessary. This can be achieved by the cloning and subsequent analysis of genes coding for parasite antigens[1-4]. Recently established cDNA banks allow the expression of cDNA derived from the simian parasite _Plasmodium knowlesi_[5] and _P. falciparum_[6,7] in _Escherichia coli_. Recombinants encoding parasite antigens have been identified by immunodetection in both banks. Two of them contain repetitive units of 11 (ref. 7) or 12 (ref. 5) amino acids. We describe here the construction of an expression bank made directly from randomly generated fragments of _P. falciparum_ genomic DNA. We detect several clones which react strongly with human African immune sera. One clone expresses an antigenic determinant composed of occasionally degenerated repeats of a peptide nonamer.

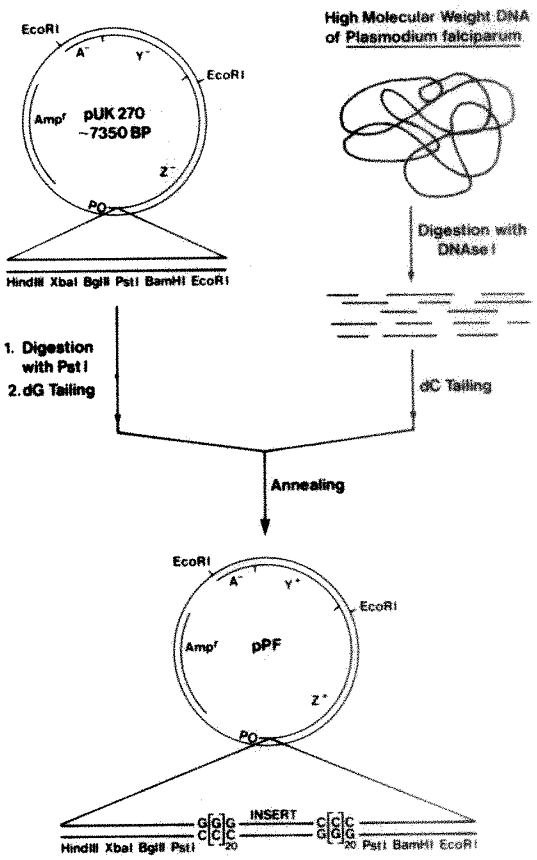

Fig. 1 Cloning of genomic DNA from *P. falciparum* in the expression vector pUK270. The vector pUK270 carries the *lacZ* and *lacY* genes with six unique restriction sites and a frameshift mutation in the promoter proximal part of the *lacZ* gene. Introduction of DNA inserts into the *Pst*I site after dG/dC tailing may overcome the frameshift mutation. Such plasmids will confer a Lac$^+$ phenotype on *E. coli* hosts which carry a deletion in the *lacZ* gene[8]. Such Z$^+$ clones can be isolated either as lactose-positive colonies on lactose minimal agar or as blue colonies on rich plates containing isopropyl-1-thio-β-D-galactoside as inducer and 5-bromo-4-chloro-3-indolyl-β-D-galactoside as indicator. The vector carrying no insert gives a pale blue colour to *E. coli* strains carrying a *lac* deletion on lactose indicator plates but does not allow growth on lactose plates. The lactose-positive recombinants express the inserted DNA as part of the N-terminus of β-galactosidase. Such chimaeric antigen-producing clones can be easily identified if antibodies directed against the expressed antigen are available[8]. Here we have modified the immunoenzymatic detection method described previously[8]. We have used nitrocellulose filters placed on lactose agar for colony replication and growth. Colonies grown on filters were lysed by dipping the filters for 1 min in chloroform at room temperature. Chloroform was removed from the filter by exposure to air for 5 min at 37 °C. Polyvinyl chloride sheets (80 mm diameter) were coated with antibodies and saturated with serum albumin[10]. We used IgG raised in rabbits immunized with Triton X-100 soluble *P. falciparum* asexual blood-stage antigens. The antibody-coated sheets were placed on the lysed colonies. After incubation for 1 h at 4 °C, the sheets were taken off and soaked in wash solution containing 0.5% Triton X-100 for 20 min. The adhering cell debris was removed by squirting with a 20-ml syringe containing wash solution over the sheets. To remove the last traces of cell debris the sheets were placed once more in fresh wash solution. The immunocomplexes were identified as described previously[8]. We used Kemp's method[6], which needs less antibody, to screen the Lac$^+$ colonies with a pool of four human African sera with high IFA titres directed against *P. falciparum* (gift of Professor Mannweiler). The mixture of antisera was cleared of antibodies directed against *E. coli* with sonicated extracts of *E. coli*. Immunocomplexes were detected with iodinated Protein A from *S. aureus*[6]. The lysed colonies were incubated with the treated human antisera after a ×25 dilution.

Fig. 2 *a*, DNA sequence of the insert of clone pPF11-1; *b*, the derived protein sequence.

We digested high-molecular weight DNA from the Palo Alto Uganda (FUP) strain[4] of *P. falciparum* with DNase I. Fragments of 50–1,000 base pairs (bp) were separated on a polyacrylamide gel and cloned into the 5′ end of the *lacZ* gene by dG/dC tailing (see Fig. 1 legend). We used the vector pUK270 that carries in the non-essential 5′ end of the *lacZ* gene several unique restriction sites. These sites introduce a frameshift into the *lacZ* gene which renders the *Z*, *Y* and *A* genes phenotypically Z$^-$, Y$^-$ and A$^-$. After cutting the vector with *Pst*I, dG-tailing and annealing with genomic fragments, only recombinants allowing read-through or restart in phase are phenotypically Lac$^+$. We identified these positive recombinants and isolated and screened 10,000 Lac$^+$ clones with antisera (Fig. 1). We screened the clones with rabbit antiserum, obtained after immunization with Triton-

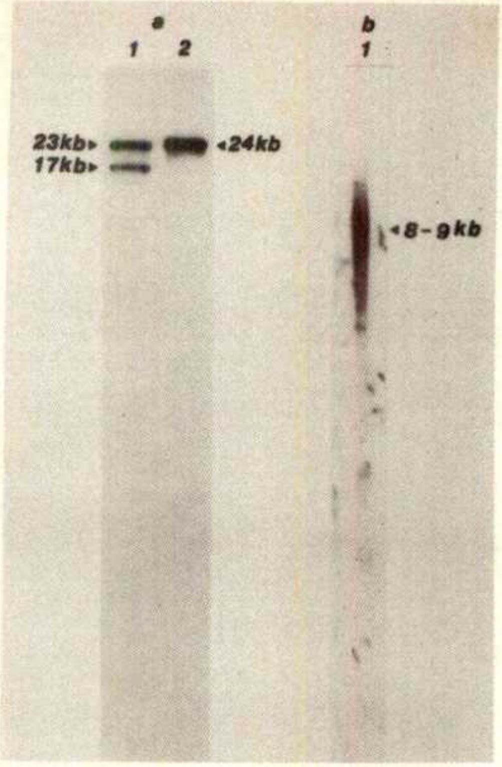

Fig. 3 *a*, Hybridization of genomic DNA of *P. falciparum* (FUP strain) with the 620-bp insert of clone pPF11-1. The genomic DNA (2 μg DNA per track) was cut with *Eco*RI (track 1) and *Hin*dIII (track 2). The DNA was fractionated on a 0.8% agarose gel, and transferred from the gel to nitrocellulose paper[13], hybridized with ^{32}P-labelled pPF11-1 probe, and autoradiographed. *b*, Hybridization of polyadenylated mRNA isolated from *P. falciparum* (blood stage) with the 620-bp insert of clone pPF11-1. 1.5 μg of polyadenylated mRNA was fractionated on a 1% agarose–formaldehyde gel, transferred to nitrocellulose paper, hybridized, washed and autoradiographed[15].

extracted proteins from *P. falciparum* asexual blood stages, using an immunoenzymatic technique[8–10]. Colonies producing antigen are visualized directly; we identified 36 positive clones with the rabbit antibodies.

We then screened 10,000 Lac$^+$ recombinants with a mixture of human sera from adult Africans living in areas endemic for malaria. Here, we visualized immunocomplexes with iodinated Protein A from *Staphylococcus aureus*[6]. Several positive clones were identified, most of them identical to those previously detected with the rabbit antisera. We present here the analysis of one antigen-producing clone, pPF11-1, which reacts strongly with both the rabbit and the human antisera in both tests. It produces a β-galactosidase fusion protein of about 140,000 molecular weight (MW) which is found in cytoplasmic extracts as a stable soluble protein and accounts for approximately 10% of the total protein. This clone contains 620 bp of *P. falciparum* genomic DNA. An insert of this length is consistent with the increase in size of the β-galactosidase fusion protein.

We next determined the complete sequence of the insert by the method of Maxam and Gilbert[11], and we found a 27-bp repeat running throughout the entire fragment. DNA sequence analysis reveals that only one reading frame contains no stop codons (Fig. 2). This frame codes for the ideal sequence Glu-Glu-Val-Val-Glu-Glu-Val-Val-Pro, but shows little similarity with the 12-amino acid repeat reported for the CS protein of *P. knowlesi*[5] or the 11-amino acid repeat found in *P. falciparum* S-antigen[7]. There is some variation in our polypeptide sequence as alanine, isoleucine or leucine can replace valine and aspartic acid or valine can replace glutamic acid. We conclude that the polypeptide probably exists as an α-helix, possibly interrupted by the prolines. The representation of this presumed α-helix according to Schiffer and Edmundson[12] reveals alternating amphipathic nonapeptides separated by proline residues, which suggests a superstructure of intertwined α-helices.

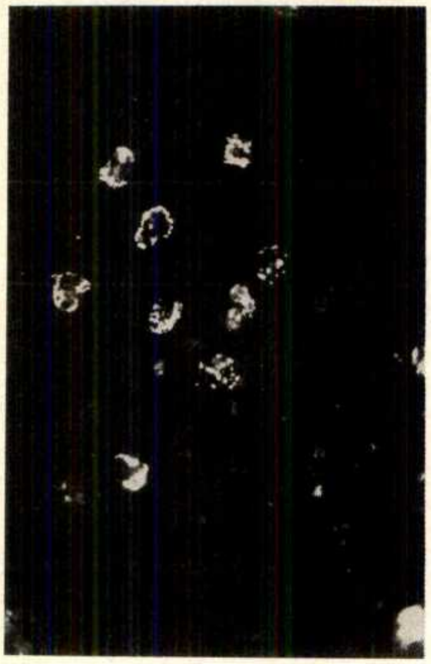

Fig. 4 Indirect immunofluorescence of *P. falciparum* antigen with anti-pPF11-1 antibodies. Thin smears of cultured parasites were fixed by acetone. The parasites were incubated with a 1/20 dilution of mouse antiserum raised against SDS-denatured 11-1 proteins and then revealed by fluorescein-conjugated anti-mouse IgG rabbit antibodies. Examination by phase-contrast microscopy (not shown) indicates that the immunofluorescence is not associated with the mature intracellular parasite but with the surrounding red blood cell membrane.

The pattern generated when pPF11-1 was hybridized[13] to FUP genomic DNA (Fig. 3*a*, track 2) demonstrates homology to a single *Hin*dIII fragment of approximately 24 kilobases (kb). We can identify two *Eco*RI fragments of 23 and 17 kbbbb (Fig. 3*a*, track 1), and single large *Bam*HI, *Aha*III, *Nde*I, *Hin*fI and *Bgl*II fragments. Sequences homologous to pPF11-1 are found in DNA extracted from a Thai isolate, K1 (ref. 14), and clone T9.96 (ref. 15)(data not shown). Our finding that the inside of pPF11-1 contains no *Eco*RI site, whereas two *Eco*RI fragments are observed in both FUP and T9.96[15] DNA, suggests that the repeated sequence spans more than 620 bp. Furthermore, a transcript of blood-stage *P. falciparum* of approximately 8–9 kb is identified[16] using pPF11-1 DNA as a probe (Fig. 3*b*). A mRNA of this apparent size could encode a protein of approximately 250,000 MW.

We raised rabbit and mice antisera against the purified fusion protein. In late trophozoites and schizont-infected red blood cells (RBC), a parasite protein can be detected by indirect immunofluorescence using these sera. The combination of phase-contrast and fluorescence microscopy indicates that the protein is located in patches associated with the membrane of the infected RBC (Fig. 4) and is not detected in ring-infected RBC or in merozoites. Using the same sera we are unable to immunoprecipitate an antigen from boiled culture supernatant in conditions where immune monkey serum immunoprecipitates an S-antigen of 200–220,000 MW. Preliminary data suggest that the 11-1 antigen has a higher molecular weight and is a minor constituent of the parasite protein. Several antigens are associated with the surface of erythrocytes infected with late stage parasites: schizont-infected cell agglutination antigen[17] which undergoes antigenic variation may be related to sequestration on endothelial cells[18]. We are currently investigating whether pPF11-1 is an antigen of this type.

Finally, concerning the difference between the commonly used cDNA expression banks (see refs 5–7) and our genomic expression bank, in a cDNA bank the most commonly expressed gene products are overrepresented. In searching for cDNA coding for a rare protein, the overrepresented cDNAs of frequent gene products have to be accounted for. In a genomic bank all genes are equally represented, therefore only one bank is needed for one organism. In cDNA there is a bias for clones coding for the C-terminal end of the particular protein; a genomic bank shows no such bias.

We thank Professor Mannweiler for the gift of the human sera, Dr J. Scaife for the K1 and T9.96 parasite DNA, Dr M. Cramer for iodination of Protein A, Dr A. Ullmann for purification of the fusion protein, Sigrid Quester, Evelyne Brunet, Micheline Guillote for technical assistance and Thierry Blisnick for growing the parasites. G.L. is a MRC/INSERM exchange fellow. This work was supported by the Deutsche Forschungsgemeinschaft through Schwerpunkt Gentechnologie and Institut Pasteur Production.

An essential property of the immune response is its ability to distinguish between self and non-self and to generate enormous diversity in antibody and T-cell immune responses. Although the genetic and molecular mechanisms responsible for antibody diversity have now largely been elucidated, the structure of the T-cell receptor and the diversification of the receptor repertoire have only recently become amenable to study. One approach has involved immunochemical studies of the protein precipitated by monoclonal antibodies which react specifically with the immunizing T-cell clones[1–3]. Another approach has been to clone and sequence a human[4] or a murine[5] T-cell specific message that may specify part of the T-cell receptor. We present here results of Southern blot analysis of non-T, immature T, and mature T-cell genomic DNA, and provide evidence that rearrangements of the *YT35* sequences do occur in the DNA of thymic leukaemia T cells. This suggests that *YT35* codes for at least part of the T-cell receptor and that rearrangements occur at this early stage of thymic ontogeny. Furthermore, DNA rearrangements are present in lymphocytes with phenotypic and functional characteristics of helper, killer, or suppressor T cells. We conclude that the three subpopulations of T cells operate via receptor molecules encoded by the same gene family.

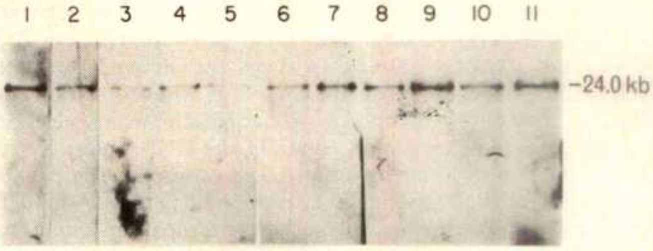

Fig. 1 Southern gel analysis of the T-cell receptor gene *YT35* in non-T-cell DNA. DNA was extracted from 11 independent samples of non-T cells and digested with 3 units of *Bam*HI per μg DNA overnight. DNA was then electrophoresed through 0.8% agarose gel as previously described[19]. DNA was transferred to nitrocellulose filters and hybridized to ^{32}P-dCMP-labelled nick-translated C35, a *Hpa*I (nucleotide 430) to *Eco*RV (nucleotide 1,087) subclone of *YT35* (ref. 4) by the method of Southern[6]. For detailed procedure, see ref. 19. Lane 1, DNA from granulocytes of a donor; lane 2, DNA from fibroblasts of the donor; lane 3, DNA from B-cell line RPMI 3638; lane 4, DNA from myeloid leukaemia cell line HL-60; lanes 5–11, DNAs from fibroblast cultures from seven different donors.

In order to determine the germ-line organization of the gene(s) corresponding to the putative T-cell receptor cDNA *YT35* and to estimate the frequency of DNA polymorphism among individuals, we have used Southern blot analysis[6] on 23 samples of genomic DNA extracted from fibroblasts (15 samples), B-cell lines (five lines), a bladder tumour cell line MGHU-1 and myeloid cell lines (two lines). The DNA samples were digested with the restriction enzyme *Bam*HI and probed with C35, a constant-region subclone of *YT35*. One 24-kilobase (kb) restriction fragment band was observed in each of the non-T cells examined (see Fig. 1). We also obtained similar results showing unchanging patterns and intensities of restriction fragment bands in non-T-cell DNA using four other restriction enzymes, *Bst*EII, *Hin*dIII, *Eco*RI and *Sph*I. These data establish that the non-T-cell DNAs from a variety of sources show no rearrangement of sequences corresponding to the putative T-cell receptor cDNA clone *YT35*. It also appears that DNA polymorphism between individuals is rare for sequences homologous to the *YT35* constant region.

To determine whether DNA rearrangements occur during or after intrathymic differentiation, we next investigated the rearrangement patterns of several thymic leukaemia lines. DNA was extracted from leukaemic T-cell lines and treated as described above. Our results show that DNA of non-T cells (Fig. 2*a*, lanes 4 and 5) contain the same restriction fragment band typical of germ-line DNA as summarized in Fig. 1. DNA from the thymic leukaemia cell lines (Fig. 2*a*, lanes 1, 2 and 3; Fig. 2*b*, lanes 2, 3 and 4) contains bands not found in the germ-line DNA lanes. When hybridization was carried out using the entire *YT35* cDNA, data consistent with DNA rearrangement in T-cell DNA were also observed, but the number of bands increased to 6 or 7 (Fig. 2*c*, lanes 2–4). In addition to the germ-line bands presented by the C35 probe, hybridization with the entire cDNA *YT35* probe reveals four new bands corresponding to the homologous variable gene segments.

Regulatory (helper and suppressor) and effector (killer) T-lymphocytes probably cooperate via complex interactions to establish a successful immune response, but the existence and relative role of the T-cell receptor in each of these subpopulations is unknown. In order to ascertain the presence of the T-cell receptor in functionally distinct T-cell subpopulations, we analysed four mature T-cell clones with helper, killer or suppressor function for possible gene rearrangements of sequences corresponding to the putative T-cell receptor clone *YT35*. All these T-cell clones were derived from the same individual and were generated by *in vitro* alloactivation against stimulating cells from a single donor[7,8].

The biological activities of these T-cell clones are summarized in Table 1. Total genomic DNA was extracted from these T-cell clones and from the autologous B-cell line derived from the same individual by Epstein–Barr virus transformation of peripheral blood B-lymphocytes. After digestion with restriction enzyme (*Eco*RI, *Bam*HI and *Hin*dIII), the DNA was analysed by the method of Southern using C35 as a probe. The results are similar for all the restriction enzymes used (Fig. 3). Although the B-cell bands (Fig. 3*a*, *b*, lane 1) retain a pattern similar to the germ-line DNA (Fig. 1), all four T-cell-clone DNA samples exhibit rearrangements of DNA homologous to *YT35* (Fig. 3*a*, *b*, lanes 2–5). Our results indicate that T-cell clones with helper, killer or suppressor activity exhibit gene rearrangement of sequences corresponding to the putative T-cell receptor gene *YT35*. The use of twin clones derived from the same individual excludes the possibility that the rearrangement is a reflection of an individual characteristic trait.

The results presented here are consistent with the somatic rearrangement of genomic T-cell DNA sequences corresponding to the putative human T-cell receptor cDNA clone *YT35*. The unchanging or germ-line restriction fragment band patterns found in the numerous non-T-cell DNA samples (Fig. 1) indicate

Table 1 Characterization of functional T-cell clones

Clone	Phenotype	T-cell functions		
		Blastogenic	CML	PFC formation
19	OKT4	DR1(r.086)	None	Helper
22	OKT4	DR1(r.083)	None	Helper
209	OKT4	DR1(r.083)	None	Suppressor
26	OKT8	None	B35	No effect
207	OKT4	DR1(0.83)	DR1	Helper

T-cell phenotype was determined by cytofluorimetric testing of reactivity with murine monoclonal antibody reacting with human T-cell surface antigens[16] (Ortho Diagnostic). Blastogenic response was determined in a 92-h ^{3}H-TdR incorporation assay. Cell-mediated lymphocytolysis (CML) was ascertained by ^{51}Cr-release assay[17]. Plaque-forming cells (PFC) induced by T-cell clones were tested as described[18].

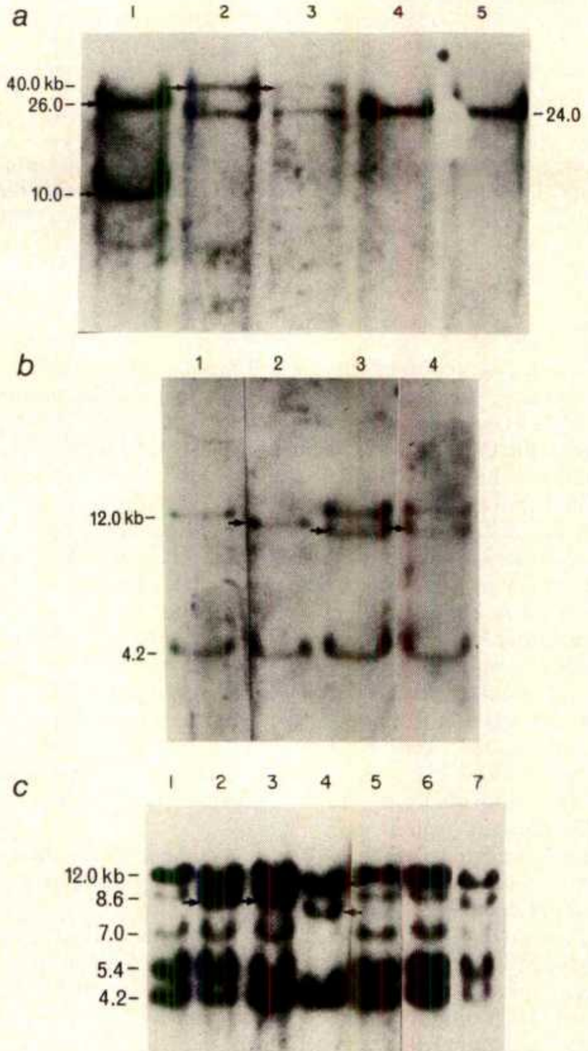

Fig. 2 Southern gel analysis of T-cell receptor gene *YT35* in DNA from thymic leukaemia lymphoblastic cell lines. DNA from thymic leukaemia cell lines MOLT-3, Jurkat and CEM, and control DNA from four non-T sources were analysed by Southern gel analysis (described in Fig. 1) using either the C35 constant-region probe (*a*, *b*) or the entire *YT35* cDNA (ref. 4) (*c*) as a probe. Arrows indicate rearranged bands. *a*, DNA digested with *Bam*HI and hybridized with C35 constant region as a probe. Lane 1, CEM; lane 2, Jurkat; lane 3, MOLT-3; lane 4, RPMI 3638; and lane 5, HL-60. *b*, DNA digested with *Eco*RI and hybridized with C35 constant region as a probe. Lane 1, fibroblast from a donor; lane 2, CEM; lane 3, Jurkat; lane 4, MOLT-3. *c*, DNA digested with *Eco*RI and hybridized with the entire *YT35* (ref. 4) as a probe. Lane 1, fibroblast from a donor; lane 2, MOLT-3; lane 3, Jurkat; lane 4, CEM; lane 5, RPMI 3638; lane 6, HL-60; lane 7, bladder tumour cell line MGJU-1.

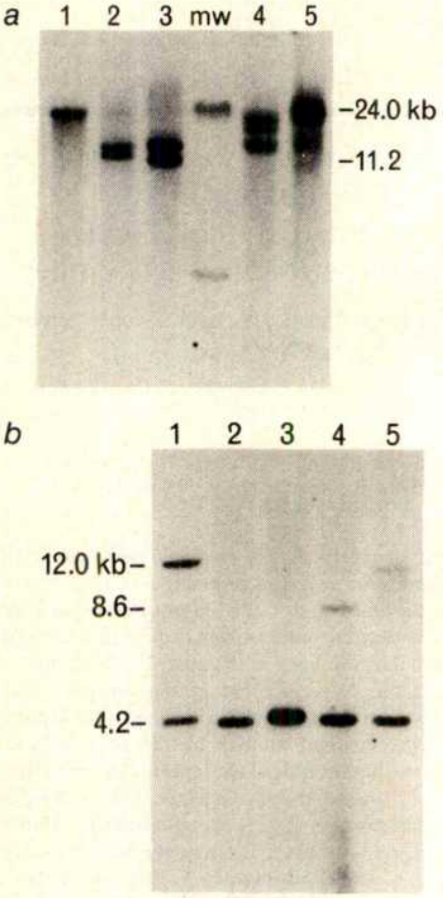

Fig. 3 Southern gel analysis of T-cell receptor gene *YT35* in DNA from five mature functional T-cell clones. DNAs and an autologous Epstein–Barr virus-transformed B-cell clone from the same individual were digested with *Eco*RI or *Bam*HI and examined by Southern gel analysis using C35 constant region as a probe (described in Fig. 1). *a*, *Bam*HI; *b*, *Eco*RI. Lane 1, LBCL (B-cell line); lane 2, clone 209 (suppressor); lane 3, clone 22 (helper); lane 4, clone 207 (helper and killer); lane 5, clone 19 (helper).

that DNA polymorphism is infrequent in genomic sequences homologus to *YT35*. The *YT35*-encoding protein thus resembles the κ light chains of mammalian immunoglobulin, where DNA polymorphism is not common[9]. It is possible that polymorphism gives rise to the inconstant restriction fragment band patterns of thymic leukaemic T-cell DNA (Fig. 2*a–c*), because we did not have the autologous non-T-cell DNA samples for comparison. To rule out this possibility, we observed DNA rearrangements in several mature T-cell clones where the autologous B cells from the same individual retain the germ-line patterns. These results (Fig. 3) suggest that DNA rearrangement in leukaemic T cells is not due to DNA polymorphisms among individuals. The increased complexity of the restriction band pattern observed on probing with the entire cDNA *YT35* (variable and constant regions) (Fig. 2*c*) implies the existence of multiple variable segments in the genome which is consistent with data analysing the germ-line genomic DNA (G. Siu *et al.*, unpublished observations). Thus, it appears that the generion of T-cell receptor diversity is accomplished by a rearrangement mechanism similar to that found in immunoglobulin production[10,11]. Immunoprecipitation of T-cell membrane glycoprotein by use of clonotypic monoclonal antibodies suggests the existence of two distinct chains in the T-cell receptor molecule[1–3]. *YT35* appears to code for one of these polypeptide chains, and further diversity can be expected to emerge through interactions with the other chain.

The non-germ-line patterns observed in monoclonal thymic leukaemia cell lines clearly indicate that rearrangement of the putative T-cell receptor gene *YT35* occurs during intrathymic differentiation in ontogenesis. Recent data demonstrate that the T-cell receptor for alloantigens is probably the most primitive one[12], and is also associated with the receptor for well-defined soluble antigens[13,14]. Our finding that helper, suppressor and cytotoxic T-cell clones exhibit rearrangement of DNA fragments corresponding to the *YT35* cDNA clone demonstrates that this gene codes for a receptor molecule which is present in all T-cell subpopulations. Furthermore, the level of mRNA expression of the cDNA *YT35* clone has been found to decrease following post-thymic differentiation of helper, suppressor and cytotoxic T cells[15]. Our data, combined with these findings, show that the *YT35* clone corresponds to a T-cell receptor gene and that rearrangement of this gene is involved in the diversification of the T-cell receptor repertoire.

Receptor gene rearrangement occurs in early ontogenetic stages of intrathymic differentiation, when T cells acquire the capacity to recognize both self and allogeneic MHC antigens. Rearrangement can also be found in helper, killer and suppressor T cells, suggesting that the three classes of cells operate via receptor molecules encoded by the same gene family. We hope that the isolation of the T-cell receptor gene from human and mouse will help in dissecting these complex interactions between lymphocytic and non-lymphocytic cells necessary for successful humoral and cytolytic immune responses.

The humoral immune system antigen-binding proteins (immunoglobulins) are disulphide-linked heterodimers of light and heavy chains. The gene for the variable region which determines antigen specificity is assembled when one member from each of the dispersed clusters of variable (*V*) gene segments, diversity (*D*) elements (for the heavy chains only) and joining (*J*) segments rearrange and fuse during B-cell development (reviewed in ref. 1). Short recognition sequences adjacent to these elements appear to be involved in the recombination process. The cellular immune system antigen recognition proteins are receptors on the surface of T cells, which are composed of disulphide-linked α-chains and β-chains, each of which has a variable and constant region[2–4]. Recently, cDNA clones of the β-chain[5] mRNA have been isolated[6,7]; the genomic arrangement is very similar to immunoglobulin genes with multiple V_β genes[8], and two clusters of J_β segments, each of which is upstream from a constant-region gene segment[9]. The V_β and J_β segments have adjacent recombinational recognition sequences like the immunoglobulin elements. However, ~10 nucleotides of the cDNA clones between the V_β and J_β regions were not present in the corresponding genomic elements and may have been due to intervening D_β segments[8,10]. Here we describe a diversity element ($D_{\beta 1.1}$) in a region of high human–mouse homology about 650 bases 5′ to the first J_β cluster. Two transcripts which include sequences upstream of $D_{\beta 1.1}$ are found in the human thymus. This region may have some other function besides providing the β-chain with a diversity segment.

We have extended our previous sequence[8] of $J_{\beta 1}$, the first of the two human J_β clusters, from 750 bases 5′ to $J_{\beta 1.1}$ to 380 bases 3′ to $J_{\beta 1.2}$ (Fig. 1*a*). This cluster is about 4 kilobases (kb) 5′ to $C_{\beta 1}$. We identified what we believe to be a diversity element, $D_{\beta 1.1}$, 650 bases upstream from $J_{\beta 1.1}$. Its position with respect to the J_β cluster is similar to that of the murine immunoglobulin heavy-chain *D* element, D_{Q52} (ref. 11) and the equivalent human element, D_{HQ52} (ref. 12). However, there is no obvious homology between $D_{\beta 1.1}$ and the human or murine D_{Q52} element, other than the recombination signal sequences which flank the elements and the stretch of guanosine residues in the 3′ half of the protein coding region (comparisons not shown). $D_{\beta 1.1}$ has the typical recombination recognition heptamer and nonamer sequences[13,14] separated by 12 bases on the 5′ side and 23 bases on the 3′ side (Fig. 1*a*). This structure was expected because the germ-line V_β gene has a 23-base spacer between the two signal sequences and the *J* segments have a 12-base spacer (Fig. 1 and refs 8–10) and indicates that the β-chain follows the same 12/23 spacer rule for recombination that governs the

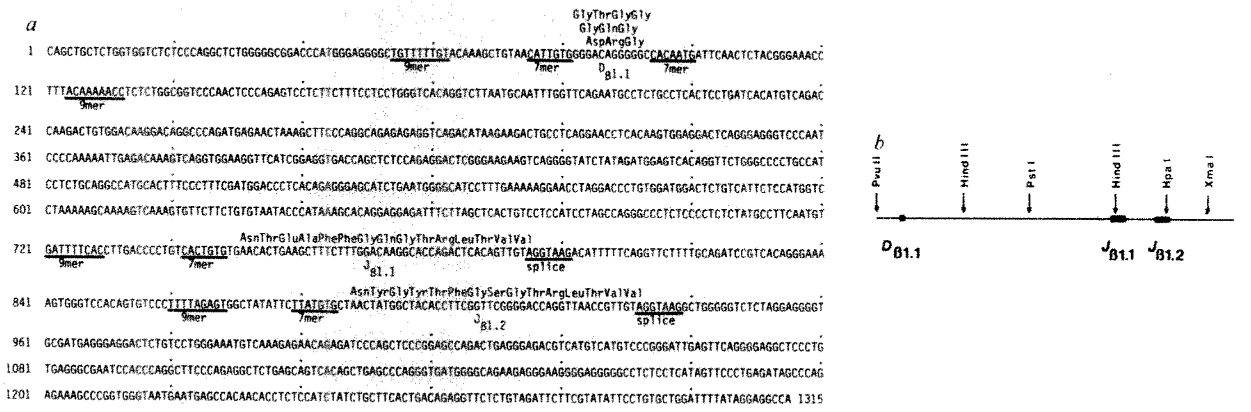

Fig. 1 The sequence which surrounds $D_{\beta 1.1}$, $J_{\beta 1.1}$ and $J_{\beta 1.2}$. *a*, The nucleotide sequence, with the $D_{\beta 1.1}$ element and the $J_{\beta 1}$ elements indicated and the translation products shown above the sequence. The heptamer and nonamer recombination signal sequences are underlined, as are the splice donor sites at the 3′ ends of the $J_{\beta 1}$ elements. *b*, A summary of the restriction sites used in sequencing and the positions of $D_{\beta 1.1}$ and the $J_{\beta 1}$ segments. The sequence was determined partly by the dideoxy chain-termination method[19] after cloning specific restriction fragments into the phage vector M13mp9 or M13mp10, and partly by the Maxam and Gilbert method[20] after 3′ end-labelling fragments at the *Xma*I site with [α-^{32}P]dCTP (Amersham) and the large (Klenow) fragment of *Esherichia coli* DNA polymerase I (New England Biolabs). All regions were confirmed by sequencing on both strands or using alternative procedures, and all restriction sites were sequenced across.

immunoglobulin genes[13,14]. Two elements can only rearrange and join if one has a 12-base spacer and the other a 23-base spacer between the recognition nonamer and heptamer sequences. However, the arrangement is different from the immunoglobulin heavy-chain *D* elements which have 12-base spacers on both the 5′ and 3′ sides. The reason for this difference, when the general organization of the β-chain elements so closely resembles that of the immunoglobulin heavy chain, is unknown but it may be a consequence of the evolution of the immune receptor family. It may be a part of a mechanism to allow the recombinatorial enzymes to distinguish between the T-cell receptor and immunoglobulin genes, or it may simply be a mechanism to allow greater flexibility in the structure of the variable region. The V_β gene segment (with the 23-base spacer) can attach directly to the J_β segment (with a 12-base spacer) without incorporating a D_β element at all (Y.Y. *et al.*, in preparation). Alternatively, it might also be possible to incorporate more than one *D* element into the rearranged β-gene.

The YT35 *D* element[8], $D_{\beta \mathrm{YT35}}$, and $D_{\beta 1.1}$ are not similar so they are probably members of distinct D_β families (comparisons not shown). Our cosmid clones of unrearranged DNA which contain about 20 kb 5′ to the $J_{\beta 1}$ cluster were analysed for other related D_β segments by probing with synthetic oligonucleotides complementary to $D_{\beta 1.1}$ and to $D_{\beta \mathrm{YT35}}$. No hybridization was observed, although the probes hybridized strongly to the positive controls (data not shown). This suggests that the D_β elements are dispersed much the same as the immunoglobulin *D* elements which are scattered over 80 kb 5′ to the J_H cluster[15]. The sequence presented in Fig. 1 was also searched by computer for human interspersed repetitive elements contained in the GenBank DNA sequences database, release 19.0, but none were found.

Northern blot analysis of T-cell RNA reveals two distinct bands that hybridize to a YT35 probe (Fig. 2). A constant-region probe detects a major band of 1.3 kb and a minor band of 1.0 kb in human thymus RNA and RNA from the leukaemic T-cell line MOLT-3 (ref. 16). The relative intensities of the two bands vary between experiments, as seen by comparing Fig. 2*a* and *b*, but the 1.3-kb band is always more intense. The C_β probe hybridizes to MOLT-3 and thymus RNA to the same extent, however, the YT35 V_β region probe hybridizes much more strongly to the 1.3-kb band of MOLT-3 than that of thymus (Fig. 2*a*), reflecting the heterogeneous mixture of *V*-region sequences found in the population of thymocytes, but does not detect the 1.0-kb band even after prolonged exposure. Thus, the 1.0-kb transcript contains no V_β sequences. To determine whether this species is the result of transcription initiating upstream of an aberrant or incomplete *D–J* rearrangement, a Northern filter was probed with the oligonucleotide D_βA30 as described in the legend to Fig. 2. Knowing the sequence of the 1.3-kb MOLT-3 message[6], we would not expect D_βA30 to hybridize to it. The two MOLT-3 bands that are observed after washing the filter and probing with this oligonucleotide may be due to traces of the C_β probe that remained on the filter, as the relative intensities of the bands are the same as when the C_β probe was used. For the thymus RNA, however, the 1.3-kb message hybridizes less strongly than the 1.0-kb message—the opposite of what is seen with the C_β probe—and a previously undetected transcript of ~0.8 kb appears. The 1.3-kb message is detectable partly because of hybridization to the 12 bases of coding region. The 0.8-kb species is not seen in the T-cell lines[16] MOLT-3 (Fig. 2*b*), Jurkat or CEM (data not shown). An oligonucleotide complementary to 40 bases immediately 5′ to the D_βA30 probe region also hybridizes to the 1.0-kb and 0.8-kb transcripts in thymus RNA (data not shown). These data indicate that at least some of the 1.0-kb transcripts initiate upstream from a $D_{\beta 1.1}$ element that has rearranged to be adjacent to a *J* segment but not to a V_β segment, as appears to occur in the mouse[17]. The lack of hybridization of D_βA30 to the MOLT-3 1.0-kb message suggests that it may be the result of rearrangement to some element other than $D_{\beta 1.1}$.

Figure 3 compares the sequences around $D_{\beta 1.1}$ with the murine $D_{\beta 1.1}$ and $D_{\beta 2.1}$ loci[17] and the similarities of the sequences in various regions are listed in Table 1. The $D_{\beta 1.1}$ elements have identical sequences, but the murine $D_{\beta 2.1}$ has an insert of two nucleotides. The high homology between human and murine $D_{\beta 1.1}$ (78% over 229 bases, which is as high as the homology between the coding regions of the human[6] and murine[7] C_β genes) was unexpected, considering the 85 Myr that these sequences have had to diverge since mammalian radiation[18]. Such conservation usually means that either the region encodes a protein with a conserved primary structure or that the region has a regulatory role. In addition, there may be overlapping functions. This extensive homology is probably not a requirement for general *D*-element rearrangement because the human and murine D_{Q52} immunoglobulin heavy-chain *D* elements do not have any similarity beyond the recombination recognition sequences (ref. 12 and our unpublished observations).

Sequences 5′ to the presumptive coding region of $D_{\beta 1.1}$ are present in the 1.0-kb transcript of immature thymocytes. Such transcripts are also found in the mouse[17]. An open reading frame extends upstream in the human and murine D_β segments, so it may be that these short transcripts encode a protein with

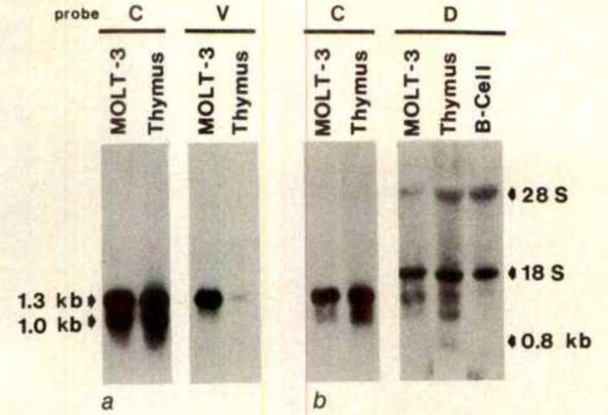

Fig. 2 Analysis of thymus and MOLT-3 RNA for transcripts containing V_β sequences, C_β sequences or 5′ $D_{\beta1.1}$ flanking sequences. RNA was extracted from the cells, electrophoresed and transferred to nitrocellulose membranes as previously described[6]. *a*, Hybridization of a YT35 constant- (*C*) or variable-specific (*V*) fragment. *b*, Hybridization with the YT35 constant-region probe (*C*).

Methods: *a*, The *C* or *V* fragment was gel-purified, nick-translated and hybridized to the nitrocellulose in hybridization solution (50% deionized formamide, 5×SSC (1×SSC is 150 mM NaCl, 15 mM Na citrate, *p*H 7.0), 50 mM sodium phosphate, 250 μg ml^{-1} salmon sperm DNA, 1×Denhardt's solution) and 1×10^6 c.p.m. per ml of probe at 40 °C for 16 h. The final wash was in 0.1×SSC, 0.1% SDS at 50 °C. *b*, The method for hybridization was as for *a*. After 80 h of autoradiography, the filter was washed three times in 0.1×SSC, 0.1% SDS at 90 °C, then exposed to film for 60 h to ensure complete removal of the probe. The 1.3-kb band was barely visible. The filter was then hybridized to the 30-base oligonucleotide probe D_βA30 (*D*; complementary to positions 93–64 in Fig. 1*a*, including 12 bases of $D_{\beta1.1}$ and 18 bases of the adjacent 5′ flanking region) which had been 5′ end-labelled with [γ-^{32}P]ATP (Amersham, specific activity 3,000 Ci mmol^{-1}) and T_4 polynucleotide kinase (Boehringer Mannheim). Hybridization was performed in hybridization buffer with 1×10^6 c.p.m. per ml at 37 °C for 16 h, then at 21 °C for 24 h. The filters were washed twice with 5×SSC at 21 °C and exposed for 10 days. The control lane of B-cell RNA shows that D_βA30 strongly hybridizes to 28S and 18S RNA, and that the 1.3-kb and smaller messages are specific to T cells.

Table 1 Homology between human and murine D_β elements and their flanking sequences

	Upstream of 5′ nonamer	Between nonamer recombination signals	Downstream of 3′ nonamer
Human $D_{\beta1.1}$ Murine $D_{\beta1.1}$	78%	90%	68%
Human $D_{\beta1.1}$ Murine $D_{\beta2.1}$	60%	75%	Random
Murine $D_{\beta1.1}$ Murine $D_{\beta2.1}$	54%	79%	Random

Fig. 3 Comparison of the human $D_{\beta1.1}$ and the murine $D_{\beta1.1}$ and $D_{\beta2.1}$ regions. The murine sequences are from Siu *et al.*[17]. Solid circles indicate identity between adjacent sequences, and dots show where gaps have been introduced to improve the alignment. The relevant regions are marked.

unknown properties and functions. A prediction arising from this hypothesis is that there should be no homology 3′ of the D_β region, which would be deleted during recombination with a J_β segment. This is indeed seen when murine $D_{\beta2.1}$ is compared with the other two D_β elements, but not when the human and murine $D_{\beta1.1}$ elements are compared (Table 1). Perhaps the 0.8-kb transcript observed in the thymus includes regions 3′ to $D_{\beta1.1}$, or possibly there is some transcript being produced on the opposite strand, where there are long open reading frames in the human and murine $D_{\beta1.1}$ regions, but not in the murine $D_{\beta2.1}$.

The presence of a prominent and discrete transcript of 1.0 kb in immature but not mature T cells from both man (Y.Y. *et al.*, in preparation) and mouse[17] suggests that this message has a function during T-cell development. The frameshifts upstream from the D_β elements suggest that any proteins resulting from distinct incomplete *D–J* rearrangements would be quite different, so might be involved in the generation of, or selection for, receptor specificity. Unfortunately, knowledge of the molecular biology of the processes of T-cell ontogeny is scarce, so it is difficult to suggest a function for this RNA species or the protein it may encode. Further characterization of the 1.0-kb transcript may allude to some of these processes, and might indicate a reason for the strong homology around $D_{\beta1.1}$ between species.

We thank S. Horvath and M. Malissen for synthesizing and purifying, respectively, the 14-nucleotide oligomer complementary to the YT35 *D* region. S.P.C. and Y.Y. are recipients of awards from the MRC of Canada. This work was supported by the MRC of Canada and the National Cancer Institute of Canada.

Isolation of UV-resistant revertants from a xeroderma pigmentosum complementation group A cell line

Brigitte Royer-Pokora* & William A. Haseltine

Department of Pathology, Dana–Farber Cancer Institute,
Harvard Medical School, Boston, Massachusetts, USA

Xeroderma pigmentosum (XP) is an autosomal recessive disease. Cells cultured from XP patients are hypersensitive to the lethal effects of UV light[1–6]. Most XP cells are defective in an early stage in DNA repair of UV light-induced damage. The nature of the genetic defect of the XP syndrome has not been defined. To address this problem, we attempted to isolate UV-resistant cells from a cell line derived from an XP complementation group A (XPA) patient. By using a selection scheme capable of detecting one UV-resistant cell in a population of 10^8 cells, several UV-resistant clones were isolated at frequencies between 1×10^{-7} and 2×10^{-8}. Here we describe the isolation and initial characterization of these phenotypic revertants.

We used the cell line designated M1 which has been characterized with respect to its histocompatibility locus antigen (HLA) type, karyotype, isoenzyme profile, restriction map of the integrated simian virus 40 (SV40) genome, and its ability to function as a recipient in transfection experiments[7]. Multiple exposures to UV light were used to select for UV-resistant clones. The frequency of occurrence of UV-resistant clones in different experiments (listed in Table 1) was in the range 1×10^{-7} to 2×10^{-8}, regardless of whether the cells had been exposed to DNA under transfection conditions, subjected to mock transfection, or subjected to selection without previous treatment. The observation that the frequency of appearance of UV-resistant colonies was the same regardless of the previous treatment of the cells indicates that the frequency of reversion to a UV-resistant phenotype is substanitally higher than the frequency of DNA-mediated gene transfer of the wild-type *XPA* allele in the conditions used. We have been unable to repeat the results of Takano *et al.*[8] using their cell line as recipient, the same source of donor DNA, and the same selection conditions. In control experiments we found that the transfection frequency of a single-copy *gpt* gene integrated into HeLa cell DNA was 2×10^{-6} per 20 μg of high-molecular weight DNA, indicating that transfer of single-copy genes can be detected using the methods outlined here.

Several tests were done to determine whether the UV-resistant cell lines were derived from the original M1 UV-sensitive parent. The morphology, doubling time and cloning efficiency of the UV-resistant cell lines were indistinguishable from those of the M1 culture. In all cases tested, the restriction map of the integrated SV40 genome was the same as that of the M1 culture (Fig. 1). The isoenzyme profile, HLA type and the karyotype are also identical to those of the parental M1 cell line (Table 2). We conclude that the UV-resistant colonies derived in these experiments are phenotypic revertants of the M1 XPA culture.

The cytotoxic effect of UV-irradiation of several of the UV-resistant colonies was compared with that of normal and SV40-transformed human fibroblasts. Figure 2 shows that although D_0 varied somewhat from clone to clone, they all were within the normal range. (D_0 is the dose required to reduce survival by $1/e$ on the exponential portion of the survival curve.)

The ability of several cell lines to support the replication of UV-irradiated herpes simplex virus was examined[9]. The plating efficiency of UV-irradiated herpes simplex virus on the resistant cell lines is comparable with that on normal cell lines and distinctly different from that of the M1 cells (Fig. 3*a*). Similar results were obtained using UV-irradiated SV40 DNA in transfection assays[10]. One revertant cell clone, XP-RH10, was tested and found to resemble the normal cells rather than the M1 cell line. We conclude that the UV-resistant cell lines tested have recovered the ability to carry out host cell reactivation.

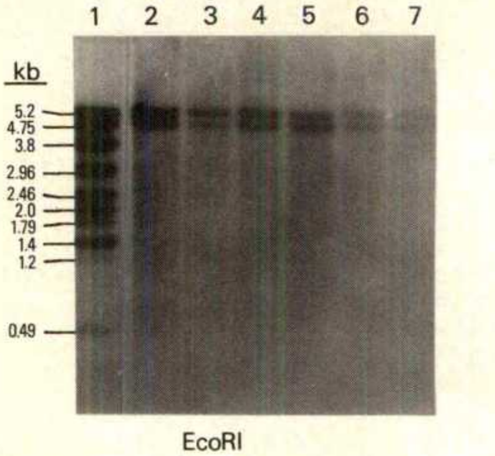

Fig. 1 Characterization of integrated SV40 DNA. DNA was isolated from the parental M1 cell line and from the revertants indicated below. The DNA was digested to completion with *Eco*RI and the sizes of the *Eco*RI DNA fragments determined by Southern blot analysis using SV40 DNA as probe, as described previously[7]. Lane 1, size markers (SV40 DNA digested with *Eco*RI, *Hha*I, *Pst*I, *Pvu*II, *Taq*I and *Hpa*II, as described elsewhere[7]). Lane 2, parental XP12RO-M1 clone; 3, XP-RE1; 4, XP-RH3; 5, XP-RH10; 6, XP-RG3; 7, XP-RG1.

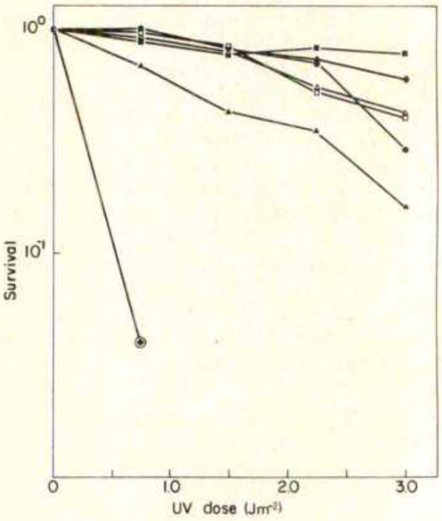

Fig. 2 Dose–response of M1 and revertant cell lines. ◈, XP12RO-M1; ▲, XP-RG1; ●, XP-RE1; □, XP-RH10; △, XP-RC12; ■, 1522, normal human fibroblasts; ◆, GM637, SV40-transformed fibroblasts. 1,000 cells were seeded per 60-mm dish and irradiated after 24 h under a layer of 1 ml Hank's buffer. After removal of the Hank's buffer, growth medium containing 15% serum was added. The medium was changed after 1 week and the plates were stained after 2 weeks. Colonies were counted and the relative survival determined as:

$$\frac{\text{number of colonies on UV-irradiated plates}}{\text{number of colonies on unirradiated plates}}$$

The relative survival values were found to be the same between experiments that were repeated at least three times for several of the clones. For the determination of D_0 values, plates were irradiated with higher doses of UV.

The ability of the cells to remove cyclobutane pyrimidine dimers from DNA can be measured by determining the number of UV-specific endonuclease-sensitive sites in DNA at several times post-irradiation. For this study, cells were irradiated with 2.5 J m^{-2}; DNA was extracted immediately and 24 h after

---

Table 1 Frequency of occurrence of UV-resistant M1 clones

Experiment	Treatment	No. of cells used	No. of revertants	Designation of clones	Frequency
a	None	1×10^7	0		$<1\times10^{-7}$*
b	None	5.3×10^7	11	XP-RB1-XP-RB11	2×10^{-7}
c	None	3×10^8	11	XP-RC1-XP-RC11	3.6×10^{-8}
c	$CaPO_4$+DMSO	2.6×10^7	4	XP-RC12-XP-RC16	1.5×10^{-7}
e	$CaPO_4$+DMSO	1×10^7	2	XP-RE1, XP-RE2	2×10^{-7}
f	$CaPO_4$+DMSO	1×10^7	2	XP-RF1, XP-RF2	2×10^{-7}
g	XP DNA	1×10^7	2	XP-RG1, XP-RG2	ND†
k	XP DNA	5×10^6	0		$<2\times10^{-7}$*
h	Normal human DNA	1×10^7	9	XP-RH1-XP-RH9	9×10^{-7}‡
g		1×10^7	7	XP-RG3-XP-RG10	ND†
k		5×10^6	0		$<2\times10^{-7}$*
g	Mouse DNA	6.5×10^6	3	XP-RG11-XP-RG14	ND†‡
h	Mouse DNA	3×10^6	2	XP-RH10, XP-RH11	6×10^{-7}‡
k	Mouse DNA	3.5×10^6	0		$<8.5\times10^{-7}$*

To select for UV-resistant clones, 2×10^7 M1 cells were seeded at a density of 4×10^6 cells in large plates (245 cm^2). Selection was begun with a UV dose of 1 J m^{-2} 24 h after seeding. The selective pressure was maintained by exposure to 0.5 J m^{-2} every other day for 2 weeks. At the end of this time cells were exposed to 1 J m^{-2} and allowed to grow for 1 week. Surviving colonies were picked and tested for UV resistance. Only colonies having a $D_0>2.2$ were scored as resistant in this assay. Reconstruction experiments using M1 and SV40-transformed normal human cells demonstrate that this selection method can detect 1 in 10^8 UV-resistant cells. The frequency represents the number of UV-resistant colonies per initial number of cells plated. Between the start of transfection experiments and plating out for UV selection, the cells doubled two or three times. For different treatments, the same letter (*a*, *b*, *c*, *e*, *f*, *g*, *h* or *k*) indicates that the experiments were done at the same time, for example in expt *c*, one part of a pool of cells was subjected to UV selection alone and another part to calcium phosphate + dimethyl sulphoxide (DMSO) plus UV selection. In a typical transfection experiment, 5×10^5 cells were plated on 60-mm plates, then treated either with 20 μg DNA per plate or with $CaPO_4$ precipitate alone, or left untreated. DNA was left on the plates for 24 h. Cells were then treated with 10% DMSO for 10–20 min. The medium was changed every day for 5 days and cells were split to low density on day 6 (3×10^6–1×10^7 cells per dish, 245 mm^2). The next day UV selection was initiated as described above. In experiments *g* and *k*, cells were split the day after DMSO treatment and UV selection was initiated on day 3 after addition of DNA.

* No UV-resistant clones were obtained for the number of cells plated, therefore the frequency is less than the indicated number.

† ND, not determined. In this experiment the frequency could not be calculated, as the colonies obtained after UV selection were pooled and reseeded before a second round of UV selection.

‡ The clones were analysed for donor DNA by Southern blotting. In the case of clones transfected with mouse DNA, DNA from the revertant clones was analysed for repetitive mouse DNA as described by Grusella *et al.*[15]. No repetitive murine sequences were found in the UV-resistant cells. XP-RH1-XP-RH9 clones were transfected with normal human DNA ligated to pSV$_2$gpt DNA, which codes for resistance to mycophenolic acid (MPA). The clones contained neither pBR322 sequences nor additional SV40 sequences, and were not resistant to MPA (data not shown). These results indicate that the UV-resistant cells contained no transfected DNA.

Table 2 Karyotype and isoenzyme analysis of the parental XP clone and the UV-resistant (UV^r) revertants XP-RE1 and XP-RG1

	Parental SV40 XP12RO-M1 clone	UV^r clones XP-RE1 and XP-RG1
Cytogenetics		
Sex	Male	Male
Near-diploid count	44%	30%
Near-tetraploid count	56%	62%
Highly polyploid	0	2%
Marker A (3q$^+$)	+	+
Marker B (14q$^+$)	+	+
Isozymes		
LDH	Human	Human
G6PD	B	B
PGM1	1–2	1–2
PGM3	1	1
ESD	1	1
Me-2	1	1
Ak-1	1	1
GLO-1	1–2	1–2

The methods used for karyotype, isoenzyme and HLA type analysis have been described previously[7]. LDH, lactate dehydrogenase; G6PD, glucose 6-phosphate dehydrogenase; PGM1 and PGM3, phosphoglucomutase-1 and -3; ESD, esterase D; Me-2, malic enzyme, mitochondrial; Ak-1, adenylate kinase-1; GLO-1, glyoxylase 1.

exposure. The DNA was treated with the UV-specific endonuclease isolated from *Micrococcus luteus*[11]. The size of the DNA samples after such treatment was analysed on alkaline agarose gels and the extent of removal of cyclobutane pyrimidine dimers from the DNA was calculated using the procedures described by Sutherland[12]. Removal of dimers from the DNA of the revertants was not distinguishable from that of wild type cells by this test.

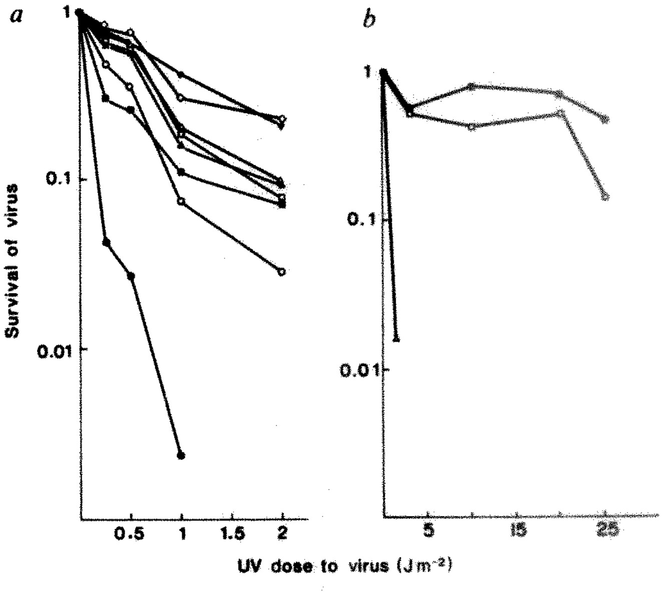

Fig. 3 Host cell reactivation of herpes virus (*a*) and SV40 (*b*). *a*: ●, XP12RO-M1; ○, XP-RE2; ■, GM637; □, SV80; ▲, XP-RE1; △, XP-RH10; ▼, XP-RH1; ◇, XP-RG3. For host cell reactivation of UV-irradiated herpesvirus, 7.5×10^5 cells were seeded on 35 mm plates. The following day, medium was removed and 0.2 ml of herpesvirus (UV-irradiated with the indicated doses) was added and the cells were incubated with the virus for 30 min at 37 °C. Then, 3 ml of medium containing 0.7% agar were added; 4–5 days later, when plaques were visible under the microscope, a fresh layer of medium containing agar and 0.015% neutral red was added. Plaques were counted either 24 or 48 h later. *b*: △, XP12RO-M1 cells; ●, CV-1 cells; □, XP-RH10. Host cell reactivation of UV-irradiated SV40 was done as described previously[10].

The ability of several of the isolates to undergo unscheduled DNA synthesis, both as measured by incorporation of ^{3}H-thymidine after irradiation of stationary cells and by counting grains overlying the nuclei, was determined as described by Royer-Pokora *et al.*[7]. These experiments showed that all the revertants tested (XP-RH10, XP-RG1, XP-RH2 and XP-RE1) were capable of unscheduled DNA synthesis.

Here we have demonstrated that phenotypic revertants can be isolated from the M1 (XP12RO) culture of XPA cells, in agreement with preliminary reports by others[13,14]. Phenotypic reversion may arise by several mechanisms including back mutation of the primary genetic defect, second-site compensatory mutations within the gene, suppression either by nonsense or missense suppressors, increased activity of a secondary pathway, or the overexpression of a defective gene product. The frequency of UV-resistant colonies observed in these experiments, between 1×10^{-7} and 2×10^{-8}, is comparable with reversion frequencies observed for other mutations. The observation that the revertants resemble the normal cells in all properties tested favours the possibility of a simple back mutation within the gene itself. Nonetheless, these experiments do not exclude other possible mechanisms of reversion. However, if phenotypic reversion has occurred by expression of a different repair mechanism, then this mechanism must resemble that which is defective in XPA cells with respect to certain biochemical properties, for example, excision of cyclobutane pyrimidine dimers.

The revertant cell lines isolated here should provide a convenient source of biological material for a future analysis of the defects of the XPA locus. These cell lines should be isogeneic with respect to all properties except for those encoded by the *XPA* locus itself.

We thank Debra Briggs for technical assistance, Judy Lippke for the *M. luteus* endonuclease preparation, Dr Betty Pancake for help with the herpes virus plaque assay, and Dr W. Peterson Jr for the cell characterization. This work was supported by NIH grant CA29294.

Genetic effects of injection of Rous sarcoma virus DNA into polar plasm of early *Drosophila melanogaster* embryos

Retroviral proviruses and the transposable elements of eukaryotic genomes are structurally similar[1–3]. The biological significance of eukaryotic transposable elements has not been examined extensively but it is known that, like prokaryotic transposons, these elements can induce mutations in adjacent genes and cause their transposition[4,5]. It is of interest to determine whether retroviral proviruses have the same mutagenic[6] and gene transposing ability as transposable elements, particularly because the retrovirus genome is assumed to have originated from transposable elements of lower eukaryotes[1]. The transfer of DNA sequences into animal zygotes or embryos by microinjection is a promising experimental approach for eluxidating their functions[7–11]: when foreign DNAs were introduced into a mouse germ line, mutations were induced[9–11] and at least in some mice, the mutation was caused by the insertion of a retroviral sequence[9,10]. We have introduced Rous sarcoma virus (RSV) DNA into a germ line of *Drosophila melanogaster*, and describe here the resultant genetic effects.

Retroviruses are evolutionarily remote from *Drosophila*. Nevertheless, when RSV was added to their food, *Drosophila* larvae and flies were found to carry such anomalies as necroses, tumours and chromosomal rearrangements. The progeny of these flies had recessive lethal mutations but no stable visible mutant lines were isolated, nor was the presence of the virus or its DNA detected in subsequent generations[12].

By using a microinjection technique, RSV or its cloned DNA fragment was injected into the polar plasm of *Drosophila* embryos at the stage when the nuclei of future germ cells migrate in that area (70–80 min post-oviposition, p.o.). We thus isolated a set of mutant lines in some of which the virus-specific sequence was detected by Southern blot hybridization. As this stage of embryogenesis takes only 10–15 min, we used a multi-dose injector[13] basically similar to that used by Spradling and Rubin[7], which allows ~1,000 microinjections per hour, so that several hundreds of synchronously laid eggs can be treated in a single experiment.

In the first series of experiments, we microinjected suspensions of 50–100 intact RSV infectious particles per embryo and among the F_2 progeny we observed some individuals with an altered eye structure, which gave rise to the *eye-deformed* mutant line[14,15]. Hybridization in solution revealed the presence of the virus-specific sequence in the DNA of the mutant flies (~1 copy of the viral genome per *Drosophila* haploid genome). It was unclear, however, whether the appearance of this mutation was accidental, or a result of the microinjection. In subsequent experiments (described below), we obtained a set of new mutant lines (Tables 1 and 2).

In some experiments we injected a fragment of RSV circular cDNA cloned in the pBR322 plasmid, pPrC 11 (see ref. 16 and the accompanying paper[17]). The use of this plasmid instead of RSV increased the yield of mutations (probably because in this way we introduced more DNA than can be formed in the embryonic cytoplasm by reverse transcription of the introduced viruses). The results of DNA analyses of several mutant lines are given in the accompanying paper[17]. The mutants analysed were: Dr-RSV^a, Dr-RSV^b (see Fig. 1*a*), Dr-RSV^c and Dr-PrC^d (see Fig. 1*b* and Table 2), the first three of which are allelic mutations that arose independently. The Dr-PrC^d mutant has a complex phenotype characterized by three types of wing anomaly: (1) dark, bubble-like wings; (2) wings with various outgrowths; and (3) wings spread out. We failed to isolate these in separate lines, as all three anomalies occurred in the progeny of each pair of flies originally carrying only one of the anomalies. It is interesting that the viral sequence is present in an unintegrated form (plasmid) in the DNA of Dr-PrC^d flies (ref. 17).

It is possible that the mutations observed in our experiments arose from genome rearrangements induced by exogenous DNA. If so, change in the level of recombination in the embryos at the stage of introduction of viral DNA might affect the mutation rate. To test this notion, we exposed the embryos to UV-light. We had found previously that irradiation of *Drosophila* embryos at stage 12 with short-wave (254 nm) UV light at 0.005 J cm^{-2}

Table 1 Results of microinjection of RSV or DNA preparations into embryos of *Drosophila melanogaster*

Material injected	No. of embryos injected	No. of surviving flies	Mutation found in F_2 progeny of a F_0 fly
RSV*	1,050	100	Dr-RSV^{a} (+)

Eggs collected during a 15 min interval were used in each experiment. Either 50–100 infectious particles of RSV in Eagle's medium, or $2–4 \times 10^5$ copies of the pPrC 11 plasmid containing the RSV DNA insert (see ref. 16 and the accompanying paper[17]) or an adequate amount of other DNA (as indicated), all in 0.2–0.4 nl, were microinjected using a multidose injector[13] into the polar plasm of embryos at the 70–80 min p.o. (25 °C) stage. The flies (F_0) that developed from the embryos were crossed individually with wild-type Oregon R, and the progeny of each pair were intercrossed to obtain the F_2 generation. F_2 flies having an altered phenotype were individually crossed with wild-type Oregon R flies; the F_3 progeny of each pair were intercrossed, then F_4 individuals with anomalies were used to obtain stable mutant lines (lethals and non-heritable anomalies were discarded by the crossing procedure). Independently obtained mutants of similar phenotype were tested for allelism by the standard complementation procedure. Brackets enclose one complementation group. Symbols in parentheses represent the results of analysis of the DNA for the presence of the RSV sequence (see accompanying paper[17] and ref. 18): +, sequence was detected; −, sequence was not detected; ?, line not analysed.

* Embryos used were wild-type Oregon R.

† Embryos used were mutant stock *wsn*; embryos were totally irradiated with UV (254 nm, 0.005 J cm^{-2}) 1 h after the microinjection.

‡ Dr-PrC^{c} proved unstable, giving rise to Dr-PrC^{e} (see Table 2).

§ Dr-UV^{a}, Dr-UV^{c} and Dr-UV^{h} proved unstable: the mutants obtained from them are being analysed.

increased the yield of recombination in the *wsn* stock by ~80% (S.D.N., unpublished observations). UV-irradiation (0.005 J cm^{-2}) of *wsn* embryos that had been injected with pPrC 11 increased several fold the frequency of occurrence of the same mutation that had been induced by the plasmid without exposure to UV (Table 1).

We obtained 18 mutant lines, five of which were unstable (one new mutation appeared spontaneously in each of these). The mutagenesis is clearly selective, and certain loci are preferred; it is unclear, however, whether this depends on the loci themselves or whether it is determined entirely by the mutagen, because the molecular mechanism of the mutations remains obscure. Virus-specific sequences were detected in five of seven mutant lines analysed (including the *eye-deformed* line described previously[13,14]). However, there is no reliable evidence that the mutations actually resulted from the insertion of virus-specific

Table 2 Characteristics of mutant lines obtained after microinjection of RSV or its cloned DNA into early embryos of *Drosophila melanogaster*

Mutation	Phenotype	Type of mutation, chromosomal localization*
Dr-RSV^{a-c}	Tergites diminutive, with uneven edges (see Fig. 1*a*)	Recessive; chromosome 2; expressed in ♀ only
Dr-PrC^{a}	Wings showing disturbed venation, fusion of M_{4+5} and R_{1+2} veins	Expressed in ♂ only; decreased viability
Dr-PrC^{b}	Black body pigmentation	Recessive; chromosome 3; expressed in ♂ and ♀
Dr-PrC^{c}	Wings showing shiny oval spots	Recessive; chromosome 2; expressed in ♂ and ♀
Dr-PrC^{d}	Wings showing three phenotypic anomalies (see text and Fig. 1*b*)	Dominant; chromosome 2; expressed in ♂ and ♀
Dr-PrC^{e}†	Tergites very small, some lacking	Dominant; chromosome 2; expressed in ♂ and ♀
Dr-UV^{a-k}	Tergites diminutive with uneven edges, some arranged cross-wise	Recessive; chromosome 2; expressed in ♂ and ♀

* For chromosome analysis, the mutants were crossed with Oregon R and *Cy*/*Pm*; *Ubx*/*Sb*.

† Dr-PrC^{e} was found among 6th-generation flies of the Dr-PrC^{c} line (see Table 1).

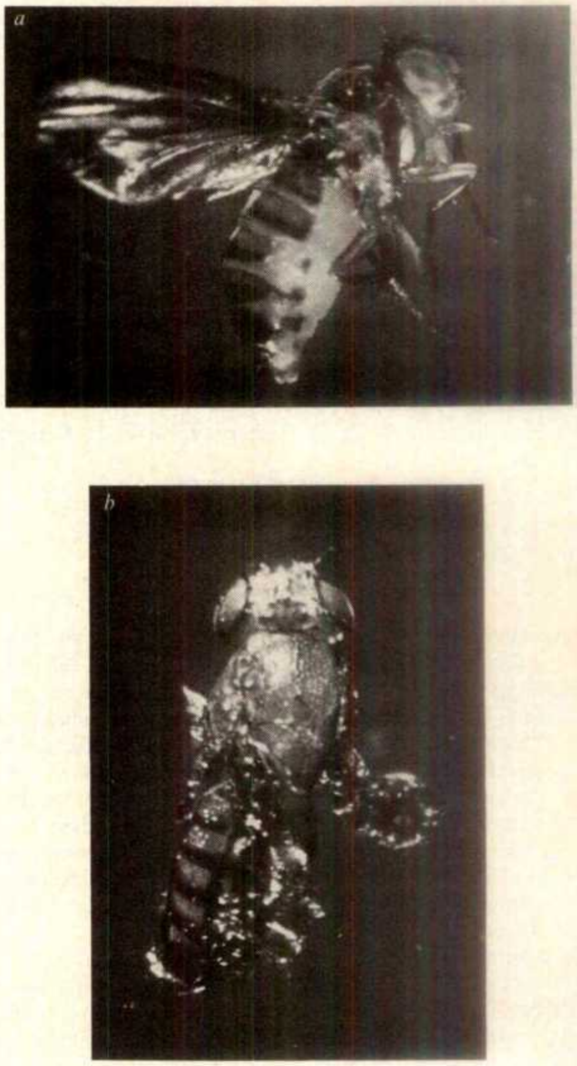

Fig. 1 Phenotypic appearance of flies of the mutant lines carrying the viral sequence (see accompanying paper[17]. *a*, Dr-RSV^{a}; *b*, Dr-PrC^{d} (the variant with outgrowths on the wings; see text).

sequences in the loci concerned, because our attempts to reveal the viral sequence in the polytene chromosomes, by hybridization *in situ*, were unsuccessful. We also considered the possibility that viral DNA derepressed endogenous elements of instability, activating them at their genomic sites or causing their transposition, a notion consistent with our major findings, namely that: (1) UV-irradiation, while increasing the general level of instability (gene recombinations), increases the frequency of plasmid-induced mutagenesis only at the locus which is already mutated without exposure to UV; (2) mutagenesis is highly selective, that is, some loci behave as 'hotspots' in the genome. It is clear, however, that some structural properties of RSV DNA are important in the development of these mutations because neither homologous DNA nor pBR32 showed any mutagenic effect (Table 1).

The injection of purified Rous sarcoma virus (RSV) (Prague strain) into *Drosophila melanogaster* (Oregon R line) eggs changes the fly phenotype in certain cases, and RSV-specific sequences can be identified in the *Drosophila* genome (ref. 1 and preceding paper[2]). Here we have used Southern blotting[3] to analyse in greater detail the proviral DNA present in several mutant lines of *D. melanogaster* produced by microinjection of intact RSV or plasmid DNA containing the viral insert. In certain populations of flies, RSV provirus was found to be incorporated into cellular DNA, and in one mutant family the unintegrated form of plasmid DNA was identified. Generally, the presence of injected genetic material in fly cells correlated with morphological changes in *Drosophila*.

DNA from mutant and wild-type lines was isolated by phenol extraction[1] and analysed by Southern blotting[3]; the morphological characteristics of the mutant *Drosophila* lines are described in detail in the accompanying paper[2]. Here we present restriction analyses of three of the mutant lines, which are quite different with respect to their viral sequence arrangements.

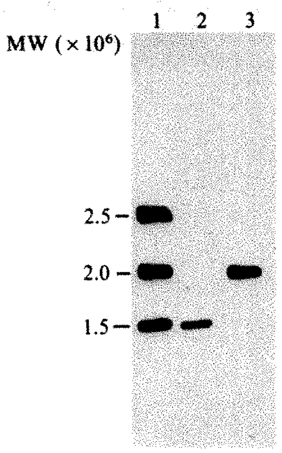

Fig. 1 Presence of RSV-specific sequences in the Dr-RSV^a genome. DNA was extracted from 1 g of flies (F_{8-10} generations) as described previously[1] and 15 µg were digested with *Eco*RI in standard conditions recommended by the supplier. Fragments were separated by electrophoresis on a 1% agarose gel. The DNA was denatured, transferred to nitrocellulose as described by Southern[3] and hybridization was performed in 50% formamide, 4×SSC at 41 °C. The probes (1.2×10^8 c.p.m. ^{32}P µg^{-1}) were: lane , RSV cDNA, prepared on 35S RSV RNA with calf thymus DNA as a primer[7]; lane 2, nick-translated pPrC-*gag* DNA containing the 1.5×10^6 dalton fragment of *Eco*RI-digested RSV provirus; lane 3, nick-translated pPrC-*src* DNA containing the 3′ part of the RSV genome located between the *Eco*RI and *Hin*dIII sites[4].

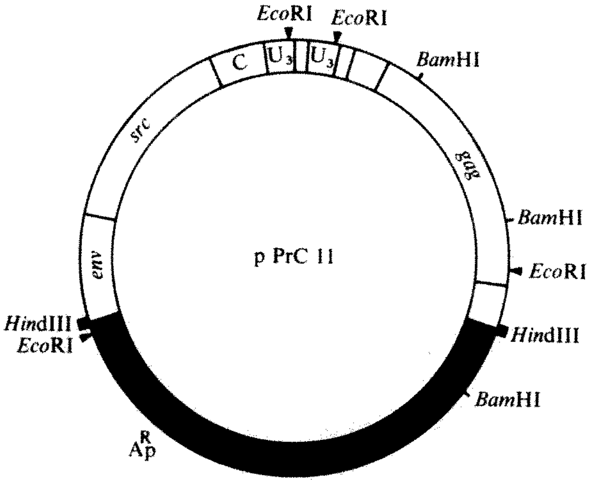

Fig. 2 Structure of pPrC 11 (ref. 4). Circular RSV (Prague strain) DNA was cloned on the *Hin*dIII site of pBR322. The total molecular weight of pPrC 11 is 6.9×10^6 daltons; the viral genome represents 4×10^6 daltons. This plasmid contains intact *src* and *gag* genes, two LTRs, the 5′ end of *pol* and the 3′ part of RSV *env* gene.

In the first restriction analysis, DNA was isolated from a mutant *D. melanogaster* population (designated Dr-RSV^a) induced by microinjection of purified RSV. The DNA was digested with *Eco*RI and, after immobilization on a nitrocellulose filter, either hybridized with total RSV cDNA or cloned fragments of viral genome containing *src* or *gag* sequences[4].

It is well known that *Eco*RI digestion of the RSV genome (Prague C strain) yields three major so-called internal fragments of molecular weight 1.5×10^6, 2×10^6 and 2.5×10^6. The two smaller fragments contain *gag* and *src* sequences respectively, while the 2.5×10^6 dalton fragment is localized in the middle of the genome and contains the *pol* gene and the 5′ part of *env*[5]. Figure 1 shows that a total DNA probe detected all three virus-specific fragments Hin the mutant line Dr-RSV^a (lane 1); the *gag* probe detected the 1.5×10^6 dalton fragment (lane 2); and the *src* probe the 2.0×10^6 dalton fragment (lane 3). These

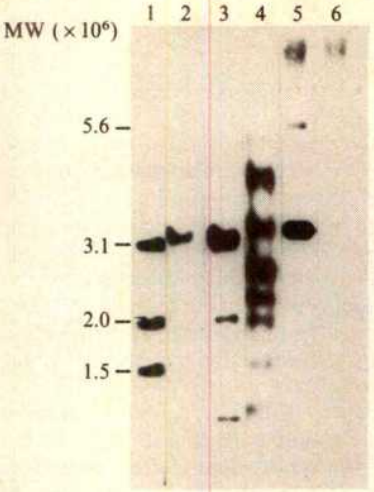

Fig. 3 The presence of pPrC 11 sequences in *Drosophila* 3A population and the Dr-PrC^d mutant line (F_{8-9} generations). 15 µg of DNA from each fly family were separated on a 1% agarose gel. Lanes 2, 3 and 5, Dr-PrC^d DNA; lanes 4, 6, *Drosophila* 3A DNA. Lane 1 contains 0.5 µg of pPrC 11 DNA. DNAs in lanes 1–4 were digested with *Eco*RI, DNAs in lanes 5 and 6 received no restriction endonuclease treatment. The probes were: lanes 1, 3–6, nick-translated pPrC 11 DNA; lane 2, RSV cDNA. Lanes 2 and 3 represent the same nitrocellulose filter which was hybridized first with RSV cDNA and, after dehybridization in 60% formamide at 70 °C, rehybridized with nick-translated pPrC 11 DNA.

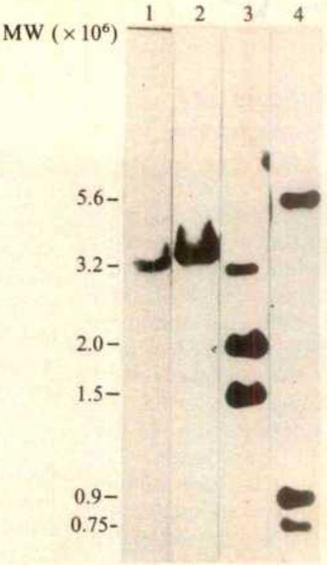

Fig. 4 Comparative restriction enzyme analysis of pPrC 11 and pDr 2A DNAs. 0.5 µg of each plasmid was digested with *Eco*RI (lanes 1 and 3) or *Bam*HI (lanes 2 and 4) then, after electrophoresis and blotting, hybridized with RSV cDNA. Lanes 1, 2, pDr 2A DNA; lanes 3, 4, pPrC 11 DNA.

data show that in this mutant *Drosophila* line, RSV provirus is co-linear with the well known genetic structure of the viral genome[5]. This DNA may persist in an integrated or extrachromosomal form, but our preliminary results with *Bam*HI and *Hin*dIII restriction lead us to suggest that provirus is associated with chromosomal DNA (data not shown).

The second example of interaction was observed on analysis of the DNA from the mixed progeny of 11 flies obtained after microinjection of bacterial plasmid pPrC 11 (*Drosophila* 3A family). pPrC 11 contains a fragment of circular RSV DNA with two long terminal repeats (LTRs) inserted in the *Hin*dIII site of pBR322 (Fig. 2). This fly population was not controlled by genetic analysis because we could not obtain a stable line. Compared with the Dr-RSV^a mutant line, the arrangement of virus-specific sequences in this population is much more complex (Fig. 3, lane 4) and essentially different from the genetic map of plasmid pPrC 11 (Fig. 2, Fig. 3, lane 1). These data show that plasmid DNA containing the viral insert can be integrated in the *Drosophila* genome. As we have been unable to obtain lines from such flies, we have not analysed further the integrated sequences.

Another example of interaction of pPrC 11 with the *Drosophila* genome was observed during analysis of the mutant line, Dr-PrC^d; this family consists of flies with dominant mutations influencing wing structure and producing three characteristic types (see accompanying paper[2]). Analysis of Dr-PrC^d DNA showed the presence of deleted plasmid DNA in which RSV sequences were observed. The main hybridization band after *Eco*RI digestion of fly Dr-PrC^d DNA was equivalent to a size of 3.2×10^6 daltons; the intensity of this band on autoradiography was much greater than that of other bands (Fig. 3, lanes 2, 3). On the basis of these results, we suggest that injected DNA may persist in fly cells of this population as an extrachromosomal element, and analysis of Dr-PrC^d DNA that had not been digested with restriction enzymes supported this suggestion. In this case, we also observed pPrC 11 sequences in the band of 3.4×10^6 daltons (Fig. 3, lane 5). In some experiments we found an additional band of 5.6×10^6 daltons, which may represent an open circular form of unintegrated DNA (Fig. 3, lane 5).

In an analogous experiment, DNA from the 3A family that had not been digested with restriction enzymes showed no indications of persistence in an unintegrated form (Fig. 3, lane 6).

We have tried to 'rescue' the unintegrated form by transformation of *Escherichia coli* HB101 strain with total DNA isolated from the mutant line, Dr-Pr^d (ref. 6). Ampicillin-resistant *E. coli* were produced which contained a new plasmid designated pDr 2A. The structure of this plasmid is essentially different from that of the original plasmid pPrC 11 (Fig. 4); its detailed structure will be described elsewhere, but it has a molecular weight of 3.4×10^6 daltons, and except for LTRs, it does not contain the main part of the RSV sequence. The possibility of insertion of *Drosophila* sequences into this plasmid has been excluded by blot hybridization experiments with DNA from the Oregon R line which gave negative results (data not shown), although we cannot exclude the possibility that a few oligonucleotide sequences from the *Drosophila* genome are scattered within this plasmid.

Our preliminary results suggest that injection of the pDr 2A plasmid into *Drosophila* embryos induced offspring carrying different mutations which produced great variations in phenotype. We conclude, therefore, that microinjection of RSV or its cloned DNA into *D. melanogaster* embryos can lead to different types of proviral DNA interaction with fly cells—persistence of the intact viral genome, integration of a rearranged viral genome and existence of the viral genome in an unintegrated form.

15-Myr periodicity in the frequency of geomagnetic reversals since 100 Myr

MAZAUD *et al.*[1] have recently analysed geomagnetic reversal time scales, covering the past 100 Myr, and they concluded that the geomagnetic reversal rate has a 15-Myr periodicity superimposed on a monotonic function, which they modelled with a lorentzian function. However, because of the analysis procedure they used, the origin (and hence interpretation) of this periodicity must be questioned. The reversal frequency as a function of time was determined using a fixed-length, rectangular, sliding window: the estimated reversal rate for each position of the window being the number of reversals appearing within the window divided by the window length. Fixed-length sliding window techniques such as this are notorious for producing spurious frequencies when used to analyse time-sequenced data generated by a process which embodies a random element. This occurs because the random component typically has a fairly broadband spectral representation and the fixed-length window acts as a filter which allows through only certain frequencies.

McFadden and Merrill[2] have also analysed geomagnetic reversal time scales and found no indication of a 15-Myr periodicity in the reversal rate. Instead, they concluded that the geomagnetic reversal process is essentially a Poisson process and that since the Cretaceous Normal Polarity Interval the reversal rate has increased approximately linearly with time. Using a maximum likelihood method they concluded that λ, the reversal rate, is given approximately by

$$\lambda = \alpha + \beta t \qquad (1)$$

where $\alpha = 4.41 \pm 0.85\,(\mathrm{Myr}^{-1})$ and $\beta = -0.051 \pm 0.014\,(\mathrm{Myr}^{-2})$ with $t = 0$ now and increasing backwards in time. A Poisson process produces randomly distributed interval lengths, τ, between events (reversals) with probability density, $\rho(\tau)$, given by

$$\rho(\tau) = \lambda \exp(-\lambda\tau) \qquad (2)$$

Using a random number generator, random sequences of interval lengths have been generated from the distribution of equation (2) with λ given by equation (1), using the point estimates of $\alpha(4.41)$ and $\beta(-0.051)$. Analysis of such sequences by the method of Mazaud *et al.*[1], using as they did a window of 4 Myr, results in estimated λ curves strikingly similar to theirs. Autocorrelation of these λ curves (after subtraction of a linear component) gives periodicities very similar to that of Mazaud *et al.*[1], yet λ contains no periodic component. Using a 2-Myr window, a similar periodicity is still apparent but buried by the (expected) increased noise. Using an 8-Myr window the amplitude of the periodicity is decreased by the increased smoothing of the longer filter.

Thus, the evidence for the observed 15-Myr periodicity being a real geodynamo phenomenon may not be as convincing as the claim of Mazaud *et al.*[1], and the possibility that λ has simply increased linearly with time and that the observed periodicity is merely a by-product of the analytical technique must be strongly considered.

2. McFadden, P. L. & Merrill, R. T. *J. geophys. Res.* **89**, 3354–3362 (1984).

MAZAUD *ET AL. REPLY*—McFadden suggests that our report of a 15-Myr periodicity in the frequency of geomagnetic reversals arises from our use of a fixed-length, rectangular window to determine the number of reversals per unit time. We are well aware that the use of such a window can introduce apparent periodicities (even for random data) because the fixed-length window acts as a filter, permitting only certain frequencies to be seen. However, when such a filter does introduce spurious periodicities, the period is directly related to the window width. In our work, we used windows ranging from 1 to 10 Myr. Although the amplitude of our periodicities and the signal-to-noise ratio varied somewhat, the period itself was confined to the narrow range of 13–17 Myr. If the period had merely been the result of using a rectangular window, we would expect a much larger variation in its value.

We now turn to the more important and more interesting point of McFadden's comment, namely, the periodicity in his computer-generated time series. Following McFadden's method we produced over 50 different synthetic time series, which were then analysed by the fixed-length, rectangular-window method. Our goal was to determine whether all of the time series resulted in periodic oscillations of the same period. In our study, the answer was clearly no: while some of the time series did give rise to a distinct periodicity, this was not the general case. In fact, we found an nearly continuous range between time series which had well-defined periodicities and those in which no clear periodicity could be discerned. This result provides additional evidence that the periodicity which we observed in the reversal frequency did not arise from our method of analysing the data. However, it also shows that a completely random phenomenon can sometimes give rise to a periodic one. With regard to the frequency of geomagnetic reversals, we certainly cannot exclude the possibility that in this particular situation, the periodicity results from a probabilistic process. In this respect, McFadden's criticism has contributed to a deeper insight of our own data.

Finally, note that we never expected that our work should serve as the final word on the nature of the reversal process. The fact that McFadden and Merrill have reached a different conclusion only demonstrates that this is a complex problem whose final resolution requires further work.

Mr Gromyko and Mr Reagan

Last week's meeting in Washington seems to have something to do with future talks on arms control, but nobody knows quite what. The best hope is that Mr Reagan will redefine his policy.

MR Andrei Gromyko caused such a stir on his visit to Washington last week that observers could have been forgiven for thinking him a candidate for the US presidency. On the face of things, he has many of the essential attributes. He has been around for a long time and he is also an elderly gentleman. But his looks belie his age, suggesting that the longevity that comes with the successful exercise of power is on his side. He is also capable of those mercurial changes of mood that, in senior politicians, pass for inscrutability; a tough hardliner's speech at the United Nations on the Tuesday, an exit from the White House with his hands clasped in the traditional boxer's gesture of self-congratulation on the Thursday. By popping in and out of the United States like this, Mr Gromyko has cleverly changed the agenda of speculation from mundane questions such as whether interest rates will rise still further (and, if so, before or after the election) to simpler issues — what did he say to the real president (who is not quite as old), and in what tone of voice?

We shall have to wait until after the election to find out. It would have been no part of Mr Gromyko's purpose to help Mr Ronald Reagan to his re-election a month from now, for which reason it was never on the cards that a tangible agreement on anything would have emerged from last month's meeting. The Soviet Union has nothing to lose, and everything to gain, from postponing serious talk about East–West relations until after the election. But there was also, last week, much to be gained from emphasizing in the run-up to election-day the importance that the Soviet Union attaches to what politicians in the West may be tempted to say in the heat of an election campaign. Mr Gromyko, at least, will not have forgotten that President Reagan's previous election campaign was marked by repeated declarations that arms control negotiations then negotiated, Salt II in particular, were Soviet traps for the unwary. In the event, the first Reagan Administration took two years to learn that that position was untenable. Nothing could have been lost, and everything gained, by reminding the incumbent president of that waste of everybody's time and of the need to avoid a repetition of that error.

It is also in everybody's interest that the momentum of arms control negotiations should pick up again once the election result is known. On the assumption that Mr Reagan will not be a lame-duck president waiting for a successor to take office, the fallow period before the next inauguration day could be used constructively, especially if Mr Reagan should let slip during the election some strictly verbal promise likely to appeal to Mr Gromyko and his fellow-countrymen (not to mention many of Mr Reagan's). An undertaking that a moratorium on the testing of anti-satellite weapons would be a precondition of negotiations on these instruments would suit capitally. (Mr Reagan will have had a chance to let that carrot show in his speech this week to the United Nations.) The temptation to seem conciliatory must be huge. There will be no complaint if Mr Reagan should succumb to it.

Preparing the ground for negotiations on anti-satellite weapons is not however what matters most. Both Mr Reagan and Mr Gromyko should remember that. For practical purposes, the agenda for arms control in the next few years should not be determined by the imagined anxieties of statesmen on either side. The US Administration's ambitions for a star wars defensive system are not an immediate threat to stability, but a threat to the anti-ballistic missile treaty (part of the Salt process) ten years from now, a threat to stability twenty or thirty years from now — and a threat to everybody's pocket-book in the meantime. The immediate issues, however, have been what they have been for ten years — the needless investment in missile systems on both sides, their fluctuating imbalance and needless pieces of irrationality such as chemical weapons. The United States is right to have been insisting that these are the subjects crying for discussion.

Can the present administration, or a successor in the same mould, bring itself to consider these questions constructively? Mr Gromyko may also have been looking in Washington for guidance on that point. Nobody can say for sure, and indeed in the past few months, there have been disconcerting signs that too many senior officials in Washington are convinced (entirely against experience) that agreements with the Soviet Union are not worth the paper they are written on. That mood, or those people, will have to be exorcised if ever there is to be serious negotiation on arms control measures that will count. Fortunately, the election provides the president with an opportunity to redefine the basis for negotiations without spilling the blood of those who have helped him loyally in the past four years. The perennial problem of politicians running for office, that of making too many speeches with too little material, might be deftly solved by using an occasional speech to lead the White House out of its old-fashioned xenophobia. It would be ironical if Mr Gromyko had been putting Mr Reagan up to that old democratic trick. ☐

Nature and the Soviet Union

ON 22 November, *Nature* will publish a survey of science in the Soviet Union.

When the project was first planned, early in 1983, it was hoped to visit a number of institutes and laboratories in the Soviet Union, but repeated requests for assistance have now been met with the information that arrangements cannot be made until 1985. Accordingly, *Nature* would be glad to hear from scientists with recent first-hand experience of work in the Soviet Union, or of collaboration with Soviet scientists and/or institutes.

Those able to help are asked to write to the editor as soon as possible at one of the editorial offices in London, Tokyo and Washington. Please include a telephone number.

Anonymous correspondence will not be dealt with. All correspondence will be confidential unless otherwise agreed. Information will not be published without corroboration. On this occasion, *Nature* is exclusively concerned with content and texture of Soviet research, not with problems of dissent and emigration. ☐

Another culprit

The largest of the British research councils is not blameless for the plight of British research.

BRITISH self-contentment over the mechanism of research support has taken several hard knocks in the past few years, nowhere more conspicuously than over what is called the dual-support system, the mechanism by which public funds for academic research are channelled from two supposedly independent sources, the University Grants Committee (which is supposed to equip university departments to carry out research) and the five research councils (which then provide project funds on a selective basis). That the system has not been working as intended has been clear at least since the 1970s, although people differ in their diagnoses of what is wrong. Two years ago, the Merrison committee (commissioned jointly by the research councils and the grants committee) put most of the blame on the universities, but last month's forward strategy published by the University Grants Committee proudly took credit, on behalf of the universities, for roughly two-thirds of the cost of academic research with British public funds. The issue of which has been the weaker link is bound to be influential in the next few months, when the British Government will have to respond both to the grants committee's strategy document (probably early in 1985) and, more immediately, to the research councils' appeal (now lodged) for extra funds.

So where should the blame lie? The universities have been lackadaisical offenders for several years, adjusting to shrinking budgets by skimping on discretionary expenditure (among which research expenditure has been conspicuous), while the general increase of teaching loads casts doubt on the grants committee's assumption that something like 30 per cent of the university salary bill is a direct contribution to research. But the faults are not all on one side. The research councils are in their separate ways vulnerable to a variety of complaints, of which the most familiar is that so much of what they have to spend is committed to their own research institutes that they have too little to spend on newly arising projects. The research council responsible for the underlying welfare of British agriculture has been the most consistently pilloried on this count, but perhaps unfairly — many of its institutes are legacies from the distant past, not merely from the time, fifteen years ago, when prudence required that research councils should keep their fixed obligations to a minimum for the sake of flexibility. In any case, this line of defence continues, agencies with responsibility for research which is strategic in character (in Britain, medicine, the natural environment as well as agriculture) must seek some measure of continuity by institutionalizing parts of their programmes. The result, however, is the now notorious difficulty of effecting change. The problem for managers in the months ahead is to create room for manoeuvre.

Headhunting

In case there are doubts about the need, the curious circumstances of the British Government's difficulty in recruiting able people as heads of the research councils is a telling reminder of malaise. The post of chairman of the Natural Environment Research Council has been filled on a caretaker basis after one person to whom the job was offered stipulated "impossible conditions" — no doubt another way of referring to a demand for assurance about the council's future prospects and its chairman's freedom of action. The vacancy at the agricultural council, which has been put out to headhunters, is yet another sign that working researchers of distinction are unwilling to turn their backs on active science so as to administer the funds that help to keep other people active. The disincentive is that both research councils' funds are too meagre to serve their stated purposes and that an applicant for one of the top jobs cannot know in advance whether some of what there seems to be to spend will be snatched away from one year to the next.

This dilemma will be further sharpened in the next few months, when the government will be required to find a successor to Dr John Kingman, the chairman of the Science and Engineering Research Council who will be leaving less than a year from now to become vice-chancellor of the University of Bristol. On the face of things, this is the most attractive of all the top jobs. The council is the largest of all, with an annual budget equal to all the others put together. Moreover, this council differs from the others in that its terms of reference are explicitly to further the cause of academic science (which is why the council was not directly constrained by the Rothschild reorganization of 1973). Yet even this huge organization is now almost as hamstrung as the others. Only a few months ago, one of the council's own sub-committee's was wringing its hands over the tiny uncommitted sums of money available for spending on what was called "core" research — research in the physical sciences not tied to one of the council's national programmes of research in high-energy physics, astronomy, information technology or what have you. The difference is that while the strategically-orientated research councils can plead that their inflexibility has been wished upon them by historical accidents, the Science and Engineering Research Council has wished its problems on itself.

Costly trends

Over the years, several tendencies have been mistakenly allowed to perpetuate themselves, not the least of which is the growth of the share of the council's budget spent on central facilities ostensibly intended as services to academic science. The cost of the annual subscription to the CERN laboratory is the most conspicuous (and recently, the most contentious) of these costs, but is a declining proportion of the whole. Other facilities, such as the neutron spallation source in Berkshire (due to come on stream in November, six months late) are modest in scale (£18 million in capital cost) but justifiable against the background of possible cancellation chiefly by the argument (as at a recent council meeting) that completion would then cost next to nothing, and thus yield the cheapest machine of its kind anywhere in the world. The council's weakness for bricks, mortar and institutions is similarly evident; its agonized consideration a year ago of the question whether there should be two major observatories in Britain (Greenwich, Edinburgh) ending with the decision to keep both (as well as a castle near the Sussex coast). In recent years, the council seems to have found it difficult to make decisions.

Matters are further complicated by the council's way of dealing with the funds it has to spend. Everybody acknowledges that spending £250 million a year is difficult, but that simple consideration does not fully account for the council's predilection for distributing spending authority to four powerful committees (called boards) rolling logs for their own special interests. Weakly, the council has allowed (even encouraged) the growth of the board responsible for engineering research without providing much in the way of objective evidence that the pattern of academic engineering research resembles in any important way that common in other fields; the most charitable explanation is that engineering is politically popular (and that engineers are a turbulent group). It is especially iniquitous that the council should have parcelled out to its spending boards responsibility for the allocation of research studentships, the stipends by which graduate students are supported in Britain. The consequence is that by the allocation of research studentships to particular university departments (in whose gift their ultimate award to students rests), the boards are able to insulate themselves from suspicions that young people's estimation of what is interesting may be different from their own. In recent years, the council as a whole has further reduced its own freedom of manoeuvre by its willingness to set up earmarked funds (trendily called "directorates") to spend money on fashionable causes, biotechnology or information technology, as the fashion strikes.

To be fair, there have recently been signs that the council has occasionally seen the error of its ways. Within the past year, Dr Kingman has tried (and failed) to combine the two most powerful of his boards (nuclear physics and astronomy), hoping in the process that similar criteria would have applied in the two very different fields. It is now also firm council policy that the proportion of the council's budget spent on central facilities will in future decline from its peak (in 1982–83) of 37 per cent. There is no sign of repentance on the way in which research studentships are allocated, but that may yet come. In all this, the council's strongest defence is that even its comparatively large budget is far too small to accomplish everything it is supposed to do, and there is force in that claim. All the more reason, however, why the council should be more vigilant than in the past in creating some flexibility within the straitjacket it has made for itself. But that will be a thankless task, hardly the kind of job which people will be flocking to secure. ☐

European synchrotron source

Strasbourg and Grenoble battle for site

THE European Synchrotron Radiation Source (ESRS), a world-rank 5 GeV electron synchrotron first planned and championed in the late 1970s by the European Science Foundation (ESF), seems likely to be built at last, at Strasbourg on the Franco-German border. Or so the auguries suggested last week, in the midst of an extraordinary political and "scientific" battle now raging between the little tourist town of Strasbourg and the French alpine city of Grenoble, both potential sites for ESRS.

The battle is all the more extraordinary after the years ESRS has spent in the wilderness. The idea for an intense next-generation synchrotron radiation source was first canvassed in 1979, when ESF (a consortium of European research councils) began touting its technical study around Europe — without success. But now, partly as the result of a poll showing a potential ESRS user community of 2,000 scientists and 600 research groups in Europe, and much interest in industry, Cinderella has become the belle of the ball.

In the latest move, the French and German research ministers have reached a deal that will place ESRS in France and (as compensation) a "European trans-sonic wind tunnel" in Cologne, West Germany. (Britain was originally in the running for ESRS, but dropped out because of the high expenditure expected of successful bidders.)

Now, with the main battle settled in favour of France, the two regional governments that might benefit have raised the stakes by throwing money (and glossy brochures) at the project. Strasbourg, the home of ESF, has bid FF 100 million ((£85 million) to win the project, and Grenoble has offered FF 80 million (£65 million) towards the FF 900 million (£750 million) cost of the machine. If ESRS were built at Grenoble, it would go alongside the high-flux neutron beam facility, the Institut Laue-Langevin (ILL), which is insisting that the "scientific case" would favour such a link.

French regional, economic and scientific policy, however, favours Strasbourg. And this is a powerful force in Paris at present, with the government seeking to decentralize and to create new regional centres of excellence. Strasbourg is also more centrally located in Europe, which is why West Germany favours it. Although Britain would prefer Grenoble, its lack of cash gives it no leverage. The choice now rests with the French Goverment. Paris sources say that Strasbourg is the likely but not certain bet in a decision that should be taken in a few weeks.

On the scientific side, the battle for ESRS appears at first sight to be between the biologists (in whose discipline the University of Strasbourg and surrounding institutes excel) and the physicists (where Grenoble is on a level with Paris).

But do the biologists want the machine? Some say yes, some say no. The directorate of the major French research council, the Centre National de la Recherche Scientifique (CNRS), wants ESRS for the biologists and so favours Strasbourg, where CNRS already runs a centre for low-energy nuclear physics and a number of important laboratories in molecular biology and where it plans a major research centre in plant biology. Many individual CNRS biologists, however, have a different view: they would prefer that ESRS stayed with the physicists in Grenoble.

According to CNRS, a Strasbourg location for ESRS would help biologists (and chemists) to become more involved with the use of synchrotron radiation and break down interdisciplinary barriers. It would also contribute to the development of Strasbourg as a centre of European science, close to West Germany and Swiss centres. CNRS biologists are worried about having to help pay for a facility that in practice they will not use. They say their budget within CNRS is already tight, burdened as it is with more than their share of an existing French synchrotron source (LURE) at Orsay, whence their preference for Grenoble.

The director of the European Molecular Biology Laboratory (EMBL) at Heidelberg is said also to be in favour of Grenoble, where EMBL has a neutron scattering facility. ILL's own case is that its own work — the instrumentation as well as scientific interests — is similar but complementary to that of ESRS, so that a Grenoble site for ESRS (or "Maxwell Institute" as ILL has already dubbed it) would be more productive than at Strasbourg. ILL says there is room (just) on its compact site for the 772-metre-circumference synchrotron, and that vibration from the nearby autoroute should not be the nuisance once feared.

Grenoble's case is strong, but Strasbourg has politics on its side. No wonder that the French science minister, Hubert Curien, says that the decision "is not proving easy".

Robert Walgate

Marinov

Further threat of immolation

BRITISH diplomatic missions in Genoa (Italy) and Vienna (Austria) have been under siege in the past few weeks by Dr Stefan Marinov, the Bulgarian physicist now living in the West, with threats of self-immolation. Dr Marinov is protesting at the refusal of the Editor of *Nature* to publish three long scientific articles, one of which is a restatement of Marinov's theory of absolute space-time, another of which announces the design of a *perpetuum mobile*.

Dr Marinov first embarked on self-immolation in Genoa on 8 August, outside the British Consulate, but by his own account was held in conversation for half an hour by staff from the consulate and was compelled to flee when the staff sought the assistance of the police, knowing that he was present illegally in Italy (having been denied entry in 1980).

At a press conference held in Austria last week, Dr Marinov again announced his plan for self-immolation, this time outside the British Embassy in Vienna. On the telephone earlier this week, he said that he would take this step at 10 a.m. local time on 2 October but, on being informed of the appearance of this piece, said "Now I don't know whether to immolate myself tomorrow".

Dr Marinov's claims that Einstein's theory of special relativity is misplaced were first made in 1974 (*Czechoslovak J. Phys.* B24, 965; 1974), on the basis of an experiment carried out in Bulgaria that purported to show that the velocity of light is direction-dependent. Marinov has since claimed to have repeated the experiment. The paper describing that investigation, "New measurement of the Earth's absolute velocity with the help of the coupled shutters experiment", says that the experiment was carried out in his girl-friend's apartment, that the rotating shutters, functioning as a siren, disturbed the neighbours and that "after a couple of altercations, my girl-friend threw away from her apartment not only my apparatus but also me".

The two other papers submitted for publication are called "On the action and interaction of stationary currents" and "*Coup de grace* to special relativity and to something else". All three papers have now been published by Marinov in his book *The Thorny Way to Truth* (Part II).

Marinov's complaint against *Nature* is primarily that publication of these three papers has been refused, but also that "milliards of dollars" are being lost each day the world remains ignorant of his perpetual motion machine. Other matters in dispute are *Nature*'s refusal to publish an appeal to the late Yuri Andropov at the end of last year and, earlier, a manifesto called the "Ten Jena Commandments".

John Maddox

Canadian science

New brooms plan clean sweep

Ottawa

CANADA's science chiefs are expecting great things from their new progressive conservative minister, Thomas Siddon. With a professional engineering background and a PhD in aero-acoustics, Siddon is highly spoken of as a friend of science and may be the man to gain some much-needed political clout for his office as minister of state for science and technology.

One of the first signs of renewed emphasis on science may be the creation of a standing parliamentary committee to deal with technology development. And by all accounts the recent Wright Task Force report urging more demand-led research and development (see below) is being taken very seriously. While some science administrators admit to private doubts about the numbers, Siddon intends to deliver his party's pledge to double Canadian research and development to C$ 10,600 million within its first term of office.

Most of this increase needs to take place within industry. Canada suffers from being a "branch plant" economy — many companies based in the United States use Canada simply for warehousing and distribution — and this Siddon is determined to change. The activities of major companies will be examined and government investment and tax measures deployed to favour more innovation within the country. There is a strong feeling that trading competitors have been making gains from various forms of hidden assistance to their domestic industries, and the intention now is that Canada should use every fiscal measure permitted under the General Agreement on Tariffs and Trade to protect its home base.

One high priority is to revise the scientific research tax credits introduced earlier this year. That scheme, intended to help young high-technology companies that did not benefit from traditional tax incentives, has already proved an embarrassment: although a boon for investment dealers, it has cost the government significant revenue and has failed to generate innovation on the scale intended.

Changes can be expected at laboratories run by government departments and by the National Research Council (NRC), which cover everything from measurement standards to cancer research. A proposed manufacturing technology centre to be run by NRC was planned by Wright as representing "everything that is wrong with federal technology policy": industry was not consulted and the facility may be redundant before it is built. NRC's technology transfer programme has failed to make a real impact on Canadian industry, and Siddon wants to contract out some NRC work to make more productive use of the laboratories.

While most Canadian universities have science departments, subject cover is patchy and there is serious concern about the future supply of highly qualified manpower. Despite Siddon's obvious enthusiasm for development as opposed to research, he "can give an assurance" that federal support for university-based research will be "continued and expanded". But this will require difficult negotiations with provincial governments, which, though supposed to support education, have in practice ensured a creeping increase in the unit cost of research supported by the research councils. Siddon also wants to encourage academics to follow through development of important discoveries by promoting the idea that consultative work for industry as well as peer-reviewed academic publications can advance a university career.

Much of this ambitious programme will depend on what sort of influence Siddon can wield in cabinet. There is room only for improvement: science and technology has at different times had to share a minister with other departments and there have been 10 incumbents of the office since 1971. But Siddon, who was a critic of science and technology in the last parliament, has 5 years' parliamentary experience, making him almost a veteran in the cabinet. The traditional hewers of wood and drawers of water had better watch out. **Tim Beardsley**

Looking south

THE Canadian economy is beset with problems stemming from its historical reliance on natural resources and its poorly-developed indigenous industry: more than 50 per cent of manufacturing industry is foreign-owned, and the *per capita* budget deficit is much larger than that in the United States. Research and development accounts for only 1.28 per cent of the Gross National Product, less than half the figure in the United States, and by the latest unofficial estimates the proportion is actually decreasing.

One major difficulty is the lack of venture capital: unlike their entrepreneurial neighbours to the south, Canadians prefer to save their money than to put it at risk, and insurance is big business. Many banks refuse to make loans for commercial ventures unless the idea has previously been tried in the United States. Canada also lacks the defence-based industries of the United States.

A hard-hitting task force report released in July urged the government to stimulate private sector research by rationalizing and simplifying industrial support schemes, providing better tax incentives and redirecting government procurement policies. The task force, under the chairmanship of Douglas Wright of the University of Waterloo, said the federal government should pay the full cost of university research, thus eliminating the political dimensions of the present research support system under which indirect research costs ("overheads") are met by provincial governments. Cooperation between universities and industry should be strengthened by a flat-rate grant to universities undertaking industrial research and development by tax concessions for industrial companies making use of universities.

Wright was highly critical of Canada's federal laboratories, some of which are "struggling to find appropriate challenges". The suggested solution was that directors recruited from industry should be given authority to set goals for federal laboratories, encouraging them to contract out research as much as possible. A formal government response to Wright is in preparation. Tim Beardsley

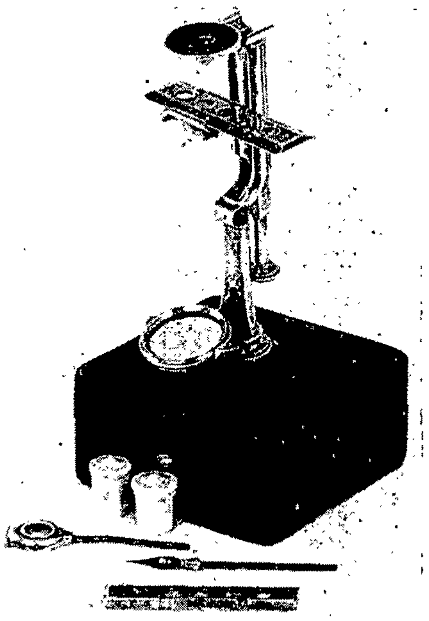
Microscope acquired



ONE of the earliest British scientific instruments to be designed, constructed and marketed outside London has just been acquired by Edinburgh's Royal Scottish Museum. The instrument, a 2-inch high silver microscope made in 1749, was a product of the workshop of John Clark, an Edinburgh goldsmith, jeweller and instrument maker. Although its eighteenth century purchaser would have been a Scots gentleman of leisure, desiring a novel curiosity, it was nevertheless the patronage of such customers that spurred instrument makers to develop the skills they would need to meet the demands of their first scientific and medical customers. The museum was assisted in making the purchase by the National Heritage Memorial Fund. □

European pollution

Towards lead-free auto fuel

Brussels

EUROPE is edging closer to a substantial reduction in exhaust pollution. But the ride has been far from smooth. Last week, the European Commission added the final flourish to proposals designed to phase lead out of petrol (gasoline). But only a few days earlier, West Germany announced its intention to apply US exhaust emission standards, which are twice as strict as those now in force in Europe, by 1989, rather than following the Commission's two-stage timetable.

With many of the 90 million cars on European roads expected to be running on super petrol by the early 1990s, the European Commission has ruled that the EEC countries should sell a single super-grade unleaded petrol from October 1989, although countries such as Italy and France, with a considerable market for small-engined cars, will still be able to sell a normal lower octane-rating unleaded petrol as well. (Unleaded petrol in Europe in fact means a lead content of between 0.01 and 0.02 grams per litre. The US content is 0.0135 grams per litre.)

Since both leaded and unleaded petrol will have to be available until old cars have been phased out, the super-leaded petrol will be marked with a red dye, to avoid mistakes in filling but also to make spot checks on "wilful misfuelling". The Commission feels price incentives should be encouraged, but this has so far been left to national governments.

Other technical specifications for the petrol (density, volatility, etc.) will be standardized by the European standards body, Le Comité Européen de Normalisation (CEN).

The proposals are the final touch to a series of European emission controls which environment ministers have to decide upon by the end of the year:

- Reducing the lead content of leaded petrol throughout the Community to 0.15 grams per litre, by 1989. Only two EEC countries, West Germany and Denmark, apply the minimum limit laid down by the 1978 EEC directive. But it is likely that the United Kingdom and the Netherlands will be allowed to impose that limit in 1986.
- Introducing unleaded petrol for new models of cars from 1989, and for all new cars sold from 1991 onwards.
- Imposing a limit of 5 per cent for benzene contained in the new petrol "cocktail" dictated by the removal of lead. Benzene is thought to be the source of a particularly toxic aromatic hydrocarbon in automobile exhausts. Some EEC countries would like the 5 per cent limit to apply to leaded petrol as well.
- Reducing other exhaust emissions (carbon monoxide, hydrocarbons, nitrous oxides) to Japanese and US standards in two stages by 1995.

Last June there appeared to be a consensus among environment ministers to adhere to the Commission's timetable. But more recently Denmark, Luxembourg and the Netherlands have seemed inclined to change to US standards in an earlier single move, and West Germany announced on 19 September that from 1 January 1989 new models of cars would have to be fitted with anti-pollution devices. The law would apply to 2-litre engines from 1988.

Whether West Germany will dare to go it alone is questionable, because of EEC rules on competition and free movement of goods. The European Commission is also doubtful about the tax incentives linked to the purchase of cars which are "environmentally friendly" (*Umweltfreundlich* in German), which could be seen as an unfair subsidy for the West German motor manufacturing industry.

While British and French car manufacturers have been quick to protest about unfair competition in Europe, West Germany fears competition just as much from the Japanese, whose ready-made models already fitted with catalytic converters for the home and US markets will, they fear, invade the West German market.

Meanwhile, Chancellor Helmut Kohl has also been severely criticized by the opposition parties for bowing to the industrial lobby, and delaying West Germany's original move to lead-free petrol scheduled for 1986.

West Germany's unilateral intentions have made a breach in the European consensus and could slow down progress on emission control in Europe unless ministers can reach a compromise before their meeting on 6 December.

Once the decision on these emission controls is taken, perhaps attention will be directed to the 10 million lorries and the 10 per cent of private cars that run on diesel fuel.

In addition to other pollutants (but not lead), diesel engines spew carcinogenic unburnt particulates (smoke) into the air. So far neither the United States nor Japan has been able to solve that problem either.

Anna Lubinska

Lead and pollution

Brussels

TWENTY per cent of air pollutants such as carbon monoxide, nitrous oxides and hydrocarbons come from the exhausts of motor vehicles. Permitted emission levels have been lowered four times since the European Community started regulating exhaust emissions in 1970.

The latest proposal involves reducing emissions in two stages to the very strict US and Japanese levels. These are as follows:

	Japan (grams per km)	United States (grams per mile)
Hydrocarbons	0.39	0.41
Carbon monoxide	2.7	3.4
Nitrous oxides	0.48	1.0

The first stage — by 1989 — aims at reducing emissions of carbon monoxide by 20 to 50 per cent (depending on the type of vehicle), hydrocarbons and nitrous oxides (which together form smog) by 20 to 40 per cent, and nitrous oxides alone by 30 to 45 per cent. Although emission levels in diesel-run cars are also to be reduced, they cannot be reduced to the same extent.

But the second stage, by 1995, requires the use of further technology. Although the development of lean-burn and fast-burn engines (which would produce less pollution in the first place) has been stepped up, the most efficient anti-emission pollution technology available today is the three-way catalytic converter. Fitted to the exhaust of a car, it chemically converts polluting exhaust emissions into the harmless components of the air we breathe: carbon dioxide, water, oxygen and nitrogen. Although research has been carried out into catalytic converters which have some tolerance of leaded petrol, their efficiency is limited.

Catalytic converters now in use are damaged by lead. Hence the need, even if lead were a doubtful health risk, to remove it from petrol. In order to fit "cats", which would reduce smog, in the early 1970s, the United States had to get rid of lead first. Europe has approached the problem from the opposite angle. Anna Lubinska

---

Weinberg *et al.* threat from animal lib

"Researchers beware!" was one of the immediate and somewhat unexpected British responses to the *Nature* conference on the molecular biology of cancer, at Boston two weeks ago. Within a week of the meeting, a document was widely distributed to laboratories in Britain, insisting that the paper presented by R. Weinberg ("Neoplasms as uncontrolled regenerative hyperplasia") would produce "horrible tissue trauma and wound healing experimentation. . . that must be publicly revealed, legally examined, morally questioned and humanely stopped".

Weinberg was accused of secretly communicating his "wretched and detestable experimentation" at a closed meeting rather than openly publishing it in the literature. How the Animal Liberation Front, the authors of the warning, intends to "punish those responsible" is unclear, but the organization claims that it will not tolerate the use of experimental animals in cancer research.

ICSU

Grand plans for global changes

Ottawa

THE International Council of Scientific Unions (ICSU) last week approved in principle a major international interdisciplinary research programme on interactions of the geosphere and the biosphere. The aim of the programme is to understand global change over long timescales, and in particular the influence of man on the environment.

Advocates of the venture, to be called the International Geosphere Biosphere Program (IGBP), argue that instruments now becoming available should be used in a coordinated fashion to monitor environmental changes that might affect human civilization as the Earth's population increases. Specific proposals are so far lacking; but the fate of carbon in the ocean and the long-term effects of high-yield agriculture on soils are likely to figure prominently.

But despite the laudable sentiments expressed last week by those seeking to avert possible environmental disaster, many were critical of what they saw as woolly thinking. Professor Tom Malone of the US National Academy of Sciences, a prominent champion of IGBP, promoted J. E. Lovelock's "Gaia" superorganism concept of the global environment, an idea most biologists find untenable. Speaker after speaker at a day-long symposium at last week's ICSU meeting emphasized the inter-relatedness of various facets of the geosphere and biosphere without specifying what new studies were needed.

Interestingly, some of the reactions heard last week may reflect the different styles of science in Europe and North America. One summary talk that featured a slide of starving children was privately criticized by some European delegates for using cheap tactics, while being praised for its effectiveness by American scientists. The second group argued that the purpose of the symposium was to stir delegates to action rather than to advance understanding.

The British Royal Society has been the leading the opposition to IGBP, believing that unless it was more carefully focused, the project could divert attention, and possibly resources, from existing international studies such as the World Climate Research Program. Some of the ideas canvassed for IGBP last week were nothing if not ambitious, with up to 50 dedicated Earth satellites being proposed. A compromise put forward by Academician V.V. Belousov of the Soviet Union and agreed by the general assembly calls for an *ad hoc* committee to work out specific proposals for IGBP in time for the next ICSU general assembly in 2 years' time. Sir Arnold Burgen, foreign affairs secretary of the Royal Society, said he was "quite happy" with Belousov's formula.

Everybody stresses that the programme is unlikely to produce data before the 1990s, and that the sort of long-term data acquisition needed will require a shift of attitudes from short-term fashionable projects towards more methodical data collection. But the success of International Geophysical Year in the late 1950s is being held up as an example of what might be achieved.

Tim Beardsley

Visas denied

THE Ottawa meeting of ICSU was marred by angry exchanges and protests by the Soviet delegation at the denial of entry visas to two Soviet representatives. A statement by the Canadian Ministry of External Affairs read out at the meeting said the government had ensured visas for "all *bona fide* scientists" to facilitate free association.

The two excluded Soviets were Dr V. K. Dobrosel'skii and Mr A.A. Kokoshin. Dobrosel'skii is, ironically a member of ICSU's standing committee on the free circulation of scientists. He is also widely rumoured to hold the rank of brigadier in the KGB (the Soviet secret police) and has previously been denied entry to other Western countries. Soviet delegates, insisted however, that Dobrosel'skii has several "outstanding" inventions to his credit. There was more puzzlement over the exclusion of Kokoshin, who is a member of ICSU's committee on science and technology in developing countries.

Most found the exclusions surprising and regrettable. There is no obvious rationale for a political reprisal by the newly elected Canadian Government, and some observers from Western nations believe Dobrosel'skii has genuinely worked for free movement of scientists regardless of what other positions he may hold. Everyone recognizes a grey area — ICSU has never consisted solely of active research scientists — and, as one US delegate observed, "we've some good scientists in the CIA" (Central Intelligence Agency). The assembly passed a resolution expressing its "deep concern" that entry visas were still being denied to scientists attending international meetings, singling out the governments of India, the Soviet Union and Canada. ICSU-sponsored activities will not be held in these countries until solutions have been found.

Visa problems also explain the Indian National Science Academy's decision to withdraw its offer to host the next ICSU general assembly; it has apparently been unable to secure the guarantee required by ICSU that scientists would be allowed entry visas. The 1986 general assembly will instead be held in Switzerland, but India may still be the host in 1988. Tim Beardsley

Drugs in athletics

Mortality of Soviet athletes

SUSPICIONS that the Soviet Union, and possibly some other socialist-bloc countries, routinely use anabolic steroids and other biochemicals in the training of athletes have now been fanned by an underground report which reached the West at the end of July, just in time for the Los Angeles Olympic Games. The report lists the names of 59 former Soviet Olympic competitors (including 26 medallists) from the 1952 games onwards, who have since died. The list, it is claimed, was compiled with the participation of Soviet athletes, many of whom fear for their own life-expectancy as a result of training procedures.

Although the list includes a few cases of accidental death not related to sports, the overall figures show a death rate of 17.1 per thousand competitors, whereas the corresponding figure for the United States over the same period is 4.5 per 1,000 and for the United Kingdom 2.1 per 1,000. Deaths occurred most frequently in the 41–50 age group (18), 31–40 (11) and under 30 (9). The death rate, according to these figures, has more than doubled since 1976, while remaining stable or even decreasing elsewhere.

We stick in doorways, and suffocate...
CCCP
BIRCH

The conclusion that these figures are related in some way to specifically Soviet training practices has been challenged by Michael Kessis, a physical education instructor in California who edits the *Soviet Sports Review* (a collection of translations from the Soviet sports press), but not, so far, by the Soviets themselves.

Thus, in a comment on "anti-Soviet" attitude in Los Angeles, *Literaturnaya Gazeta* did not deny the deaths but merely pointed out that Vsevolod Bobrov, the hockey-player, had been "approaching 60" when he died (he was in fact 57) and that Valerii Kharlamov (another hockey-player) and Valerii Popenchenko (a boxer) had died in "tragic accidents".

Apart from accidental victims, the

deceased athletes received no obituaries in the Soviet media, but the TASS correspondent in New York, Vladimir Kikilo, was able to confirm a number of the deaths. Given the uncertain provenance of the document, it would otherwise have been necessary to check its contents by a scan of the Soviet sporting press for the last recorded appearance of the listed competitors.

Mortality of Olympic medallists (1952–76*) by age group at time of death

Age	Soviet Union	United States	Germany (FRG & GDR)**
30 and under	9	7	3
31–40	11	1	3
41–50	18	4	4
51–60	7	1	2
61 +	1	1	0

*The 1980 Moscow games are omitted from this survey due to the US boycott.

**Figures amalgamated because in 1952 East Germany did not compete and from 1956 to 1964 the two Germanies fielded a joint squad.

The ban on the use of anabolic steroids for athletes makes it difficult to obtain statistically significant data on their long-term effects. Earlier this year, however, *The American Journal of Sports Medicine* listed no fewer than twelve steroid-related disorders, ranging from testicular atrophy in males and virilization in females to hepatic dysfunction, hypertension, changes in cholesterol composition, tumours, changes in connective tissue and psychosis.

There have also been suggestions that the Soviets may be administering to their athletes carnitine (involved in fatty acid metabolism), potassium orotate (an intermediary in the biosynthesis of pyrimidine nucleotides) and inosine (also involved in pyrimidine nucleotide synthesis and in the formation and breakdown of high-energy phosphates). Such compounds could serve both as performance enhancers and to counteract the short-term side effects of steroids. The long-term effects of high dosages are, however, unknown.

The mortality report on Soviet athletes — if accepted abroad — could serve as a grim warning to athletes and trainers in other countries who might feel tempted to resort to unauthorized aids. The status of the document, however, is still far from decided. Attempts by the "Smolosky" human rights group in the United States to bring it to the attention of the International Olympic Committee in Los Angeles proved unsuccessful.

Part of the explanation for that may have been the absence of a Soviet Olympic team, which in turn is held by many in Eastern Europe as well as the West to have been caused by Soviet reluctance to submit athletes to the sophisticated drug tests installed at Los Angeles. **Vera Rich**

Heavy-ion research

European ambitions multiply

GANIL, the new French accelerator for heavy ions at Caen in Normandy, is to close down for January to save electricity. GANIL must save 12 per cent as its contribution to last year's budget cuts, but director Claude Detraz is not perturbed. "We're stopping in January when electricity is most expensive", he says, "and anyway we're finding we've got plenty to do when the machine's off."

In fact, Detraz is buoyant about the performance of his accelerator. He is even happy with his budget — which he believes to be quite sufficient to "sweep the field" in intermediate energy heavy-ion collisions. Detraz claims that GANIL is three years ahead of any other accelerator in performance and beam intensity and is making many interesting — and unexplained — discoveries. What GANIL needs, he says, is not money but a team of committed theorists to help explain the effects being revealed.

The accelerator at Caen is the latest of a clutch of European heavy-ion machines (others are in West Germany and Britain) dedicated to the study of the gross properties of nuclei rather than the structure of nucleons and other particles, with which high-energy physics is now preoccupied.

Detraz says he is enticing French theorists to GANIL with discoveries such as that of isolated excited states of the nucleus 100 MeV above the ground state (where previously only a continuum of states was expected), the apparent failure of thermodynamic models of the excited nucleus and strong forward scattering (a kind of nuclear transparency) at total nuclear energies above 40 GeV. Other GANIL products (detectable because of high beam intensity) are exotic neutron-rich nuclei such as nitrogen-23, neon-29 and neon-30 as well as highly-charged positron-emitting atoms. "It's a gold-mine", says Detraz.

GANIL, however, is not alone in the mine. In Britain, working another seam, the Nuclear Structure Facility (NSF) may have taken a lead in high-spin nuclear physics, where nuclei are spun to such angular momenta that Coriolis and centrifugal forces are comparable with nuclear forces. NSF is planning a major extension of its Van de Graaff accelerator, the largest in existence, by means of a superconducting linac.

In West Germany also, the heavy-ion laboratory (GSI) near Darmstadt is basking in the discovery of elements 108 and 109, and has won outline approval for a substantial extension. And Italy is building an advanced superconducting cyclotron in Milan, although the project was set back recently by the untimely death of its designer.

GANIL itself uses a pair of separated-sector cyclotrons to accelerate a wide range of nuclei from 100 MeV per nucleon (for light ions) up to 10 MeV per nucleon (for the heaviest). In low-energy nuclear accelerators (such as NSF), nuclei approach at velocities that are small compared with the internal velocities of their nucleons, so that internal structures are rearranged before collisions. At much higher energies (such as the GeV per nucleon available at Berkeley, California), on the other hand, collision velocity is much faster than the internal motions, and nuclei collide like bags of stationary separate particles. But at GANIL — the intermediate region — the velocities are roughly equal, so that simple approximations do not apply. Hence perhaps, the lack of enthusiasm of theorists, whom Detraz claims are nevertheless being won round by the challenge of GANIL.

NSF (at Daresbury, Cheshire) is making its mark because of its stable and turnable particle beams (a consequence of eletrostatic acceleration), the range of nuclei which can be accelerated ("virtually the whole periodic table" according to a Daresbury experimenter), and a superb detector of gamma-emission from high spin states which can discriminate against Compton-scattered radiation.

Daresbury now plans to abandon the original target of a 30 MV terminal voltage, to stay with the present 20 MV but to put all its effort into developing a superconducting linac stage after the Van de Graaff. This would give NSF the capability of colliding uranium with uranium. The proposal has not yet gone to the nuclear physics board of the Science and Engineering Research Council that would fund it, but the extension could be built segment by segment without increasing the budget, they say in Cheshire.

Meanwhile, GSI Darmstadt plans to add a synchrotron and a storage ring to its present UNILAC linac (which is capable of colliding nuclei at around 20 MeV per nucleon). The additions would bring GSI up to 1.3 GeV per nucleon at high intensity, making possible a search for new states of condensed nuclear matter. The GSI additions are all but finally approved, a federal government spokesman in Bonn said last week, with a decision due "before the end of the year".

With work in this field also at CERN (the European Organisation for Nuclear Physics near Geneva) and progress in Italy, the chauvinistic cry is getting louder in Europe that the old continent has taken "an unquestionable world lead" in nuclear matter studies. That, of course, was what the particle physicists were saying until President Reagan gave the go-ahead to the super-conducting super-collider now being built as an adjunct to the Stanford Linear Accelerator Center and which may steal a march on CERN's new large electron-positron storage ring. **Robert Walgate**

Japanese research

Companies go for basics

Tokyo

A BUILDING boom for basic research laboratories is under way in Japan — but neither the government nor the universities can take credit. Instead it is large private corporations that have begun to invest in academic research.

The latest is Meiji Milk Products, whose brand-new Institute for Basic Research in the Life Sciences, located in Odawara City, some 80 km from Tokyo, will be completed in the next few weeks. The initial outlay has run to 5,000 million yen ($21 million). Around 50 scientists will be employed, together with 50 support staff, to carry out research in eight divisions spanning the whole of molecular biology.

Before Meiji Milk came onto the scene, some fifteen other companies had opened basic research facilities this year alone. The biggest surge has come for the life sciences, with six new laboratories — and a demand for researchers that has sent head-hunters in search of Japanese working in US and European laboratories. Close behind come laboratories for new materials and electronics. Famous names include robot-builders Fanuc, whose factory, where robots build robots, was toured by Mrs Margaret Thatcher, the British Prime Minister, and Toshiba, with a new very large scale integrated circuit research laboratory. Almost all the new high-technology fields are represented: artificial intelligence, molecular memories and conducting polymers all have their new facilities.

At Meiji Milk's Meiji Institute of Health Science (which bears an "MIH" logo reminiscent of a certain US laboratory) there is no pressure at all to perform applied research for company products, according to Norio Nakatsuji, until recently at the MRC Mammalian Development Unit in London and now head of the new institute's developmental biology division. He also points out that recruiting highly qualified staff has proved easier than expected — some have given up tenured positions at universities to join the institute where, with new facilities (including four P2 and two P3 biological containment research laboratories) and generous budgets, there will be no limits on research.

The basic laboratory boom is a very recent phenomenon — only one such laboratory was set up in 1982 and seven in 1983 — but it seems likely to continue. Fifteen companies have already announced plans to set up basic facilities in the near future.

What exactly is the thinking behind the boom and why are corporations prepared to spend huge sums of money to set up these laboratories? Financial analysts admit to finding the trend quite puzzling. Increased prestige is one factor they all cite, adding that prestige is often reflected in higher stock market prices when plans for basic research facilities are announced. But the real factor seems to be an underlying feeling that Japanese corporations have drawn level with or passed their Western competitors in mastering applications of current technology, and must now look for the seeds of new technology in their own basic research rather than continuing to import ideas or to look for ideas in their own universities.

Barriers between universities and industry are said to be just too high for effective research cooperation, and the new laboratory boom has not been accompanied by a boom in either university endowments or research contracts at universities. Instead, corporations seem intent on giving select groups of their own researchers the kind of freedom that they would enjoy in universities.

Given this trend, it is likely that the difference between Japan, where industry pays two thirds of the total research and development bill, and countries like the United States, where it pays only 40 per cent, is likely to increase — and Japanese university laboratories will have finance, equipment and technical support far inferior to those of their industrial counterparts. **Alun Anderson**

Virus diseases

Immunogen for herpes, AIDS?

A DRUG developed as long ago as the early 1970s is now being hailed by its makers, Newport Pharmaceuticals of California, as a possible "new hope in herpes and AIDS". Unlike the recently introduced drug acyclovir, the "new" drug (inosine pranobex, new UK trade name Immunovir) acts by stimulating the patient's immune system, not directly against the virus.

Going by the results so far, however, it is either too early or too optimistic to welcome Immunovir as a major weapon against either genital herpes or AIDS (acquired immune deficiency syndrome, linked with human T-cell leukaemia virus type III). Clinical tests, carried out by Dr R.D. Miller and co-workers at the University of California's Irvine Medical Center, have indeed shown an effect on recurrence rate in genital herpes. In 35 patients given Immunovir tablets, 18 (51 per cent) had only 0 to 1 recurrence during the six-month study, compared with 8 of 41 (19 per cent) on placebo. The relatively high apparent response to placebo, inevitable when considering symptoms that recur at unpredictable intervals, makes it impossible to assess the efficacy of Immunovir until more clinical trials have been completed.

But the initial clinical trials do suggest that Immunovir significantly reduces viral shedding — the number of viruses present in the body's secretions. This raises the hope that the spread of herpes might be controlled by treating infected individuals. The US Center for Disease Control (CDC) estimates that there are between 5 and 20 million cases in the United States, with some 300,000 new cases each year. Herpes is not a notifiable disease in the United States, hence the uncertainty of CDC estimates. Dr Miller's own estimate is as high as 30 million cases.

Whatever the true figure, there is clearly a place for a drug that would both reduce discomfort (number of recurrences) in those with the disease and reduce the possibility of them passing it on. The makers of Immunovir claim that it is cheap enough (compared with extremely expensive antivirals) and safe enough to be used in such a role. No side effects have yet been found, it is claimed, although the drug is metabolized to uric acid so cannot be used in patients with gout or kidney disorders. For treating primary herpes, with the aim of a cure that would mean no further need for treatment, it seems likely that an antiviral drug such as acyclovir will be necessary.

Immunovir has not yet been used to treat patients with AIDS, although Dr Joyce Wallace and Dr J.G. Bekesi of Mount Sinai Hospital and the AIDS Medical Foundation, New York, have treated patients with "pre-AIDS". That condition is characterized by depression of the immune system and lymphadenopathy, and may or may not develop into AIDS as defined by CDC. In these patients, as in others given Immunovir, the number and activity of natural killer cells in the blood and the number of (antibody-stimulating) T-helper cells were increased.

Improvements in laboratory tests of immune function may not always be accompanied by a clinical response. But in the 16 pre-AIDS patients with significantly improved immune responses (of 20 treated), 5 reported a subjective improvement in symptoms and were well a year after the study. Clearly, as Dr Wallace stresses, it is too early to say whether Immunovir is likely to revolutionize the treatment of AIDS and pre-AIDS, although she is encouraged to carry out further trials, and a new trial is due to begin in London later this year.

Although publicity for Immunovir has centred mainly on herpes and AIDS, the drug has shown some promise in a variety of virus diseases — hepatitis, mumps, subacute sclerosing spondylitis and influenza among them. Initial results, however, seem to suggest that amelioration of symptoms is more likely than a complete cure. **Charles Wenz**

Australian science

Budget dismays even ministers

Canberra

IF they needed reminding of it, Australia's scientists had their political impotence brought sharply home to them when the federal budget was announced at the end of August. In a fiscal strategy aimed at promoting business confidence by reducing the budget deficit to $A6,745 million (£4,500 million) from last year's $A7,961 million, and smoothing the Labor Party's path to re-election by means of a small tax cut immediately before the federal polls (now tipped for November or December), the feebleness of the science lobby was made painfully obvious.

The science and technology minister, Mr Barrie Jones, is reported to have contemplated resignation from the ministry over the budget cuts to his portfolio, and later to have earned the prime minister's displeasure by hinting publicly that taxation would increase after the election. Beyond exhorting scientists to make the public more aware of the value of their work, Mr Jones did not elaborate on the tactical details of the successful science lobbying.

Including government appropriations for salaries, administration and major capital expenditure of $A596 million — a monetary increase of 1.6 per cent over the 1983–84 figure — funds totalling $A660 million will be available through the Department of Science and Technology, if industry subventions and earned revenue are taken into account. Complaining of the new budget's effect on morale, Dr Paul Wild, chairman of Australia's largest research group, the 7,000-strong Commonwealth Scientific and Industrial Research Organisation (CSIRO), reported that CSIRO's direct budget appropriation of $A322 million intends no provision for inflation in non-salary operating funds and that most areas of CSIRO research will face cuts of up to 4.3 per cent.

An estimated 180 CSIRO jobs will be cut, mostly those of young scientists in short-term non-tenured positions. Already, the staff of at least one CSIRO division have agreed to take leave without pay to bring down salary costs and minimize retrenchments. To keep things in perspective, though, the government has set aside $A30 million for Australia's defence of the America's Cup yacht race in 1987.

The science portfolio has suffered considerably compared with the others, which is especially disappointing given the importance accorded it in the national technological strategy. The government's total outlays, excluding health, represent an average monetary increase of 10.7 per cent across the whole economy. With a projected inflation rate of 6 per cent, the 1.6 per cent monetary increase for government-sponsored science and technology results in a net contraction of about 4.5 per cent in real terms.

At $A1,237 million, tertiary education commission grants for universities have kept pace with inflation and grants to colleges of technical and further education have increased by 23 per cent to $A307 million. The Australian Research Grants Scheme, however, has had its funds augmented by only $A3.5 million to $A26 million to meet grant applications for 1985 totalling $A65 million.

Budget provision for medical research grants has been increased by $A6 million to $A44 million. Defence science has an extra $A11 million, taking its budget to $A158 million. Support for the Bureau of Mineral Resources has increased from $A23 million to $A31 million.

An addition of $A150 million over five years to the research funds available for automobile design through the Australian Industrial Research and Development Incentives Board arises from the design facility of the Button car plan, formulated by Industry and Commerce Minister, Senator John Button.

Mr Jones is nevertheless bravely burying his disappointment by a recitation of the bright spots in the budget. Antarctic research and the Bureau of Meteorology are to enjoy considerable increases, and modest support will be given to marine sciences, the National Biotechnology Scheme, fifth generation computing and a new CSIRO Division of Information Technology. Nonetheless, the minister's exasperation could not be disguised. He remarked that in an election year, short-term political considerations will always displace the longer perspective necessary in science. **Jeffrey Sellar**

US election

Shoestring lobbies

Washington

IN an election campaign that has seen optometrists and freight-forwarders organize Political Action Committees (PACs) to channel money to candidates favourable to their causes, scientists seem almost strangely absent. The records of the Federal Election Commission reveal only a handful of PACs concerned with scientific issues, and these, by any standard, are woefully impoverished.

Organizers of science-oriented PACs blame their poor showing on an "ivory tower" attitude among scientists who refuse to see scientific interests as the basis for political organization, and on the "bad name" that PACs have received. The result of post-Watergate election reforms, PACs are the only legal means by which organizations not affiliated with a candidate can make campaign expenditures. Although PACs are allowed to contribute no more than $5,000 to any one candidate, there is no limit on the amount that can be spent on "independent" advertising opposing a candidate; PACs have come to be associated with such "negative advertising" campaigns.

The Science and Technology PAC, or SCITEC–PAC, which claims to represent the interests of research scientists most directly, has so far spent only $643 during this congressional election; it has made no campaign contributions at all this year. The organization's treasurer, David Garin, says that the group plans to donate a total of $1,000 to about a dozen candidates in the next three weeks. Garin said the average contribution to the PAC was $40 per person. (Corporations and labour unions are not permitted to contribute to PACs.)

At least two somewhat more successful PACs concentrate on space issues. The Campaign for Space, which has the stated aim of promoting a balanced manned and unmanned civilian space programme, including both construction of a space station and an increased programme of planetary exploration, has taken in about $40,000 for this election; the group plans to contribute $10,000 to congressional and senatorial races. The group has also endorsed the re-election of President Reagan, citing his support for the space station and Democratic challenger Walter Mondale's opposition to the shuttle when he was in the Senate.

The other space group, called SPACEPAC, has taken in $60,000 for the election, spending almost all of it so far on fund-raising costs. Its only campaign contribution has been one of $300 to Representative Don Fuqua, chairman of the House of Representatives Science and Technology Committee.

Thomas Frieling, executive director of the Campaign for Space, readily acknowledges that the small contributions of his and other science-related PACs cannot make much difference to the election results. But, he notes, even the "big league" PACs are limited to contributing $5,000 to election campaigns that cost hundreds of thousands of dollars in the House and millions in the Senate. Garin, of the SCITEC–PAC, suggested that the real significance of his contributions was that they represent an endorsement by a non-partisan group that has the interests of science at heart.

The one scientific professional society that has organized a PAC, the National Society of Professional Engineers, dwarfs these efforts; it has so far raised $200,000 for this election. And nobody else comes close to the American Medical Association's $3.6 million war-chest.

Stephen Budiansky

Peer review

Sir — The problems of peer review procedures deserve serious consideration, but the remedy proposed by M.C. Goodall (*Nature*, 23 August, p. 620), an effective appeal process, is not practicable. Grants committees have little difficulty in identifying outstanding or mediocre proposals; it is the predominant mass of attractive sound applications that cause the problems. In the "good old days", virtually all of these would have been supported. Today a large proportion fail, their fates being determined by slight variations in the (usually secret) scoring by various members of the committee. Mean scores determine a rank order which is the basis for allocating funding from the top of the order until the funds are exhausted.

It would be quite iniquitous to review at appeal a single application that had failed without also reviewing all the competing (even successful) applications, perhaps even including those that were successful. Who is to say that a second complete review would be any more just than the initial review? In a situation of diminished resources it has to be accepted (albeit reluctantly) that a considerable element of chance is an inescapable component of today's review procedures.

The only marginal improvement that might be worth considering would be a more sensitive scoring system in the critical region around the anticipated cut-off point. For example, at present one major grant award-body scores from 0 (bad) to 6 (outstanding) with a funding cut-off in the region of 3.7. In practice most good applications are scored either 3 or 4 by committee members and the mean score can be moved from one side of the cut-off point to the other by just one member altering a score from 3 to 4, or vice versa. If members could score in fractions in this region rather than integers they could exercise greater discrimination, giving a somewhat less chancy mean score.

Nature bingo?

Sir — It occurs to me that the current "Bingo War" in Fleet Street may pose a serious threat to the maintenance of *Nature*'s circulation. May I therefore suggest a way in which this might be countered? I propose the institution of a new game entitled "Base Sequence". Each subscriber would be sent his own "DNA card" on which would be printed a unique sequence of 36 bases. Three or four tRNA anticodons would then be printed in each issue of *Nature* (possibly at the bottom of the contents page), the winner being the first reader to match up his base sequence with a complete set of complementary triplets, thus completing his peptide. Obviously frame-shifts and "spare" bases could not be allowed!

I feel certain that such a course of action would assure the future of the journal, the only possible disadvantage being the risk of attracting the eye of Rupert Murdoch or Robert Maxwell.

Brazilian science

Sir: — Your special offer for Brazilian scientists to purchase *Nature* is important not only in helping Brazilian scientists to keep themselves up to date in science, but also in calling attention to the isolation from the international scientific community of Brazilian scientists due to the present policy of budgetary restrictions for science and education. The faculty members of the Brazilian federal universities are involved in a national struggle for better working and teaching conditions. Among other facilities that are becoming inoperable, the libraries are at the moment incapable of renewing their subscriptions due to lack of money for education in addition to the restrictions on foreign exchange.

Bio company launch

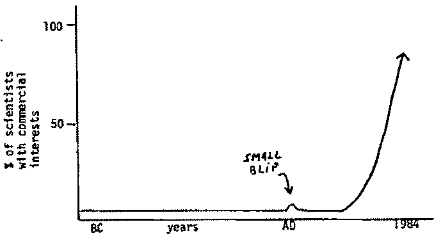
Sir — Since *Nature* has a long standing interest in promoting advances in biotechnology, we have chosen to make the first announcement of our new venture in your pages.

At a recent meeting of the American Society of Biological Chemists (ASBC, San Francisco, June 1983), we were amazed by the number of biochemists who are owners, co-owners or owned (as "consultants") by private enterprises. Our unbiased survey of participants at this meeting revealed the following (see figure).

At the time of Adam and Eve, less than 0.001 per cent of all living scientists were engaged in profit-yielding activities. Much later (see small blip in curve) a sizeable percentage of scientists convinced the public that lead could be transformed into gold. In the 1980s, this logic has been extremely successful[1,2]. There are a number of explanations for the rapid increase shown in the figure other than blatant greed including (1) new techniques for producing monoclonal antibodies; (2) gene cloning; (3) gullibility of the public.

At the San Francisco ASBC meeting, we were quite embarrassed not to have an official company business card, as did all our friends. Furthermore, when walking back to our sleazy hotel (Taylor Street, *et al.*) late one night, we were approached by two charming women asking "would you like a little company?" This encounter sparked our interest and we decided to start our own enterprise.

As indicated on our tastefully designed letterhead, Genasex was conceived. The response has been fantastic. In our travels, many scientists have expressed keen interest and overt jealousy. Suggestions arrive daily. One colleague advised changing our name from Genasex Ltd to Genasex Unlimited. A colleague from Milan offered to head an Italian subsidiary to be called Gen-italia, but we have postponed a decision on that.



What products does our company produce? So far, none. The reasons for this policy include (1) our observation that many of the new biotechnological companies also produce no products; (2) of those who do, most are in the red; and (3) to use this company as an effective tax write-off, we must be careful not to be too successful.

Hitherto, our financial investment has been negligible. Naturally, we solicit readers' contributions and would certainly consider adding names to our board of directors. Our real hope is that another company, perhaps with a similar name, would offer to buy us in order to avoid the inevitable competition.

Photocopying

Sir — J.D. St Aubyn (*Nature* **304**, 678; 1983) correctly stresses that it is publishers and not authors who are concerned about large-scale copying. In fact most reputable suppliers of tear sheets or photocopies, ourselves included, adhere to the requirements of the Copyright Clearance Center (CCC), so eliminating most of the administative copying.

The price of an authorized photocopy includes the CCC payment, I believe the British Lending Library has agreed to pay CCC fees on all photocopies mailed to the United States.

Jumping the smoking gun

Are antibiotics in animal feed a threat to human health? Contrary to some opinions, the latest evidence put forward in the United States is inconclusive.

ALTHOUGH Western Europe has now banned the use of antibiotics as a growth-promoting additive in animal feeds, the United States has since 1977 — when a proposed ban was blocked by Congress — maintained that additional data are needed to justify such an action. Half of the 35 million tons of antibiotics manufactured each year in the United States end up in animal feed; not surprisingly, the prospect of a ban is not looked upon favourably by the pharmaceutical industry.

But neither is it by farmers. The evidence, as paradoxical now as it was when the growth effect was discovered in 1949, is nonetheless convincing that chickens, pigs and cattle do much better when fed subtherapeutic doses of antibiotics. Even when the animals show a significant percentage of resistant bacteria in the gut, the effect persists; chickens, for example, will gain weight as much as 10 per cent faster when fed antibiotics[1].

Balanced against this convincing economic benefit, however, is mounting concern about the spread of resistant organisms. The discovery that resistance can be conferred by mobile plasmids, and the appearance of certain resistant strains of gonorrhoea, *Haemophilus influenzae* and dysentery-causing organisms, has led to repeated calls for cutting back "inappropriate" use of antibiotics; a prime target is their use in animal feeds. The case has always been circumstantial: although it is known that resistance-conferring plasmids do occur in animal-borne microorganisms and that plasmids can readily be transmitted to other bacteria, there has been a lack of convincing proof that the end result actually is the production of resistant strains of human pathogens. A major complication in any effort to establish such a link is the other half of the US antibiotic production, the half that ends up in humans, not infrequently for reasons that range from the inappropriate (ingrown toenails) to the unethical (as placebos for treating colds).

Now, proponents of a ban claim to have found the smoking gun. A study published last month in the *New England Journal of Medicine*[2] traces an ampicillin–carbenicillin–tetracycline-resistant salmonella infection in 18 persons to a beef cattle herd that was the probable source of hamburger eaten by at least 13 of the patients. The cattle had been fed subtherapeutic amounts of chlortetracycline; no therapeutic doses had been administered. The bacteria in all of the patients showed identical resistance and contained a 38-kilobase *R* plasmid; and these bacteria were identical with salmonella isolated from the tissue of a dairy calf that died of scours on a farm adjacent to the beef feedlot. No samples of hamburger were tested, however. In an editorial in the same issue of *NEJM*[3], Stuart Levy of Tufts University, a longtime critic of the use of antibiotics in animal feed, asserts that this study establishes an "important missing link", and concludes that "the clarion is strong and clear".

But the clarion may sound differently, depending on where one is sitting. Salmonella is one of the few pathogens common to animals and humans; it is facile to point to this case as proof that subtherapeutic antibiotics in animals can lead to antibiotic-resistant diseases in humans. Salmonella is a dangerous organism whether it is resistant or not. It should never be present in meat, whether it is resistant or not. Treatment of salmonellosis does not involve the use of antibiotics. The entire story makes a stronger case for ensuring proper sanitation in meat processing and for cooking your hamburger than it does for banning antibiotics in cattle feed.

Even more to the point, 12 of the 18 patients had been taking antibiotics, most for questionable reasons, when they became ill. Three had taken the drugs without the direction of a physician, using pills left over from an earlier prescription or from a family-member's prescription; the others had had them prescribed for sore throats or bronchitis. Because the gastrointestinal symptoms appeared very rapidly after the patients began taking the drugs (usually a matter of 1–2 days), it seems likely that they already had an asymptomatic infection that flourished as soon as competing, non-resistant bacteria were wiped out by the antibiotics. The important conclusion that cannot be overlooked is that if those concerned had not been taking the drugs — and most of them probably should not — they would not have become ill. (Much is being made of the fact that one of the 18 patients died. According to the authors, he received his infection from an incompletely disinfected sigmoidoscope that had just been used on one of the salmonellosis patients.)

Rather than a "compelling" case for the banning of antibiotics from animal feed, as Levy would have it, the study begs the question whether animals are a significant generator of resistant human pathogens. Just as it has been insufficient merely to lay out the theoretical possibility that resistance in animal bacteria could be transferred to human pathogens (a possibility that no one disputes), so it is insufficient to demonstrate, however elegantly, that meat contaminated with resistant salmonella can make people ill. The real question is the extent to which resistance engendered in animal bacteria is responsible for the spread of resistance to strictly human pathogens, such as gonorrhoea. Levy's argument that we have to worry more about antibiotics fed to animals than antibiotics fed to humans because animals produce more faeces is unconvincing. The real missing link is the extent to which human pathogens have an opportunity to interact with animal pathogens and to acquire resistance plasmids. This is surely the limiting factor in determining the animal-feed contribution to resistant human pathogens. Speaking vaguely about the "environmental pool" of resistance plasmids makes little sense in the absence of an answer to this question.

One recent attempt to look at the big picture in fact suggests that there are mechanisms in the environment that indeed limit the spread of resistance. Barbara Atkinson and Victor Lorian have reviewed tests for resistance made on 43,250,000 bacterial samples in 242 hospitals from 1971 to 1982 and have found no overall increase in resistance to 15 different antibiotics during this period[4].

Indeed, the very fact that none of the bacteria residing in the gut of farm animals is resistant suggests that some equilibrium has been reached. If, in a couple of hundred thousand generations, bacteria have not become totally resistant in the face of assault by subtherapeutic antibiotics, is it merely complacency to assume they never will? It seems plausible that the energy cost to the bacteria of maintaining resistance plasmids is at least one countervailing force in the equilibrium equation.

If nothing else, all this should convince us that we do not risk imminent disaster by delaying regulatory action until we understand better the spread of resistance plasmids.

Materials science

Making fuel for inertially confined fusion reactors

from Robert W. Cahn

THE proceedings[1] have recently been published of the Third Topical Meeting of Fusion Reactor Materials, held in September 1983. The very varied and exhaustive papers on tokamaks and their numerous materials problems include nothing whatever on the design and fabrication of the fuel micropellets needed for inertially confined fusion (ICF) reactors. Indeed, ICF is not mentioned anywhere. What accounts for this absence?

The previous meeting in this biennial series (held in August 1981)[2], and a brief attempt to gaze into the future of fusion power, published in the same year[3], likewise had no mention of this important topic. If, however, we go back to the First Topical Meeting[4], held in January 1979, we find a group of nine papers concerned with ICF fuels, covering in considerable detail the position at that time concerning the design of the fuel microspheres, their fabrication and characterization, and the tricky problem of protecting the first wall of an ICF reactor from rapid series of mini-explosions. Why the near-total silence since then?

A very readable review paper on 'the special materials in laser fusion targets' has just been published[5]. The manuscript was received by the editor of *Res Mechanica* in April 1983, and the author states that he is presenting "the state of the technologies in making these materials, and problems encountered in their development, as of March 1980". So it seems, possibly because of the connection of these technologies and problems with the military uses of lasers, that a security blackout descended after March 1980. I have seen a reference to a "1980 Topical Conference on Inertial Confinement Fusion in San Diego" but no indication that the proceedings were published. Even with what we have, however — the 1979 papers and this 'postdated' 1980/1984 paper — it is possible to see the quite extraordinary complexity of the problems and techniques involved. Hendrick's[6] assertion that "pellet fabrication is not a trivial task as implied by some reports; it is also not the impossible task implied by others" is to be noted.

ICF reactors are designed on the basis of the inertial confinement principle — a huge energy pulse imparted by laser or particle beam implodes a spherical shell of frozen deuterium–tritium mixture with a view to satisfying the Lawson criterion and setting off a series of microthermonuclear fusion explosions, the heat from which is absorbed and utilized to make power. In their review paper Farnum and Fries[5] discuss the early stages of the development of a complex laser fusion target designed for maximum fusion yield when irradiated with 100 kJ of infrared light from a CO_2 laser with 1 ns pulses. The essential parts consist of a glass microballoon coated internally with a layer of deuterium–tritium fuel and externally with a dense 'pusher' layer, the whole separated by plastic foam from an external dense metal pusher layer which is itself coated by an ablative plastic layer which creates the 'rocket' effect.

The difficulties arise from the extreme precision needed in the sphericity, thickness uniformity of layers, smoothness of surfaces (to within a few nm) and uniformity of density, for instance of the plastic foam — and all this for microspheres usually well below 1 mm in external diameter. Microballoons can be bought commercially at $\$10^{-9}$ each, but their quality is hopelessly inadequate; the new paper outlines methods, starting either from liquid drops or from solid fragments in free fall, for making balloons with the requisite geometrical perfection. These thin shells can be filled with a gas mixture while in the gel state and then vitrified. (The method for turning the gas filling into a liquid spherical shell that is then frozen so rapidly that gravity has no time to distort it was described earlier[7]; this is really a kind of splat-quenching direct from the gas phase.) Problems connected with the buckling of the microballoons under gas pressure, and the effect of thin coatings on the buckling resistance, are discussed by Farnum and Fries.

The second part of their paper deals comprehensively with ways of making smooth uniform coatings of metals, polymers or a combination of these, by various forms of physical or chemical vapour deposition. These methods often depend for their efficacy on methods of levitating the spheres to be coated, either by systems of gas jets or even by whirling them around, during coating, in a form of synchrotron[6]. Remarkably perfect polymer coatings can now be produced; one method is to build up monolayers of 100 nm-diameter latex spheres under electrostatic attraction, discharge the layer and start again. Production of polymeric foam to the requisite specification, however, is still not possible to the necessary uniformity (or at least was not in 1980).

One of the rare publications to appear since 1980 that deal with ICF pellet (or 'target') production is a paper from Livermore National Laboratory describing the use of an array of gas microjets to levitate a pellet, to allow an ultrasmooth polymer surface layer to be made by plasma polymerization[8].

One curious technique that is not discussed in Farnum and Fries's paper is the approach to making thin flanged micro-hemispherical shells by methods based on microelectronic technology. For instance, starting from circular etch-windows in a silicon surface, hemispherical depressions of high perfection can be etched; these are then boron-doped by diffusion into a thin surface layer and etched from the back with an etchant that does not attack boron-rich silicon[9]. It is a striking tribute to the micromechanical precision of modern silicon handling that the necessary smoothness and sphericity can be attained in this manner.

Others have recently urged the use of metallic glass microballoons and this is exciting much interest[10,11]. Such hollow microspheres can be formed by exploiting the instabilities of hollow liquid jets. Microballoons of a dense Au-Pb-Sb glass have been made with surface smoothness and sphericity of a very high order. How such balloons are to be incorporated in a complete target is not disclosed. Such metallic glasses are known to be highly permeable to hydrogen and thus should not be difficult to fill with fuel. More generally, Lee has very recently outlined a range of other uses for metallic microballoons made from unstable hollow jets, including a rocket fuel[12]. A new technology seems to be emerging.

It would seem that a new generic name is required for the congeries of techniques which have been developed to make ICF fuel pellets — 'materials microtechnology' perhaps? When the full account of this work is published, it will be seen as an essential part of the history of modern materials science and technology. But we shall have to await wholesale declassification before we can know how successful the ICF approach to nuclear fusion currently is. Meanwhile, the interested reader is referred to a concise textbook[13] on thermonuclear fusion that discusses the essential characteristics of inertial confinement. □

Geology

Seismic reflections of the continental crust

from Simon L. Klemperer

A recent symposium* provided the opportunity for scientists from seventeen countries to discuss their most recent results on the structure of the deep continental crust using reflection seismology. Unusually for a technique used in pure science, reflection profiling was originally developed commercially for exploration of sedimentary basins, and therefore is available for immediate application without prohibitive developmental expense. The meeting demonstrated its versatility as a means to investigate a wide variety of geological issues in the crystalline rocks of the crust.

Many of the most dramatic successes of reflection seismology have come through tracing fault-plane reflections to surface outcrop. This has resulted in the discovery of major crustal features such as the Southern Appalachian overthrust, and the Outer Isles thrust. When basement reflections cannot be tied to information from surface exposures or boreholes, their interpretation may be ambiguous. The use of forward modelling, that is, estimating the expected reflection character from basement features observed at the surface, as a first step towards interpretation was demonstrated by J. Percival (Geological Survey of Canada) for the Kapuskasing granulite zone and the adjacent amphibolite-grade Wawa gneiss belt. He speculated that the irregular horizontal-to-discordant intrusive boundary between these metamorphic zones might appear as a Conrad discontinuity in a refraction experiment. Felsic-mafic layering in the granulite zone might be the cause of layered reflections in the lower crust, contrasting with the largely felsic (reflection-free?) gneiss belt above the granulites.

The origin of highly-reflective layered lower crust is obscure, and has attracted considerable speculation. Two contrasting theories were proposed with several workers arguing for magmatic processes, such as underplating of the crust, as the primary cause for the reflective layering with extensional shear or thrusting taking a secondary role.

By contrast D. Matthews (Cambridge University) proposed the existence of lamellae of hydration or of high pore-water pressure as the major cause of lower crustal reflectivity. The presence of water or graphite in the lower crust would reconcile the observed highly-conductive zones in the lower crust with data from laboratory experiments. Clearly, more detailed geophysical and geochemical modelling as well as more detailed geological mapping are called for.

Clear reflections at about Moho depth, or bands of reflections terminating at about Moho depth, are not uncommon on deep reflection profiles, particularly extensional terranes, as seen, for example, in the Consortium for Continental Reflection Profiling (COCORP) data from the Basin and Range, and in the British Institutes Reflection Profiling. Syndicate (BIRPS) data from the British marginal seas. Near-vertical reflection seismology does not accurately define volocities at Moho depths, but it is in terms of a velocity change that the Moho is conventionally defined. In the absence of velocity data, the reflection Moho must be picked on the basis of seismic character.

P. Barton (Cambridge Univesity) made use of the best available set of coincident refraction and near-vertical reflection profiles to show that in the North Sea, the reflection Moho, defined as the base to the reflective lower crust, coincides with the refraction Moho. By contrast, D. Okaya (Stanford University) asserted that in the Basin and Range, the base of the layered lower crust, or the reflection Moho, is not coincident with the refraction Moho, although in this case, the available reflection and refraction profiles are in different locations. A. Hirn (Institut de Physique du Globe), using wide-angle reflection and refraction data, and D. Matthews, using near-vertical reflection data, demonstrated the existence of Moho offsets along faults, causing sudden changes in Moho depth of several kilometers across narrow zones.

The reflection character of the Moho, where observed as discrete reflections, varies from complex layering to simple single reflections (L. Braile, Purdue University; R. Phinney, Princeton University). Braile suggested that the disparity between wide-angle reflections, on which the Moho may appear as a continuous boundary, and the near-vertical reflection Moho, which typically lacks horizontal continuity, could be due to fine-scale lamination of the Moho. D. Blundell (Chelsea College) used simple 3-D ray-tracing models to show how a single surface, suitably cross-folded into an egg-box structure, appears as a thick band of reflections on a stacked seismic section, due to interference of reflected arrivals from different directions. These complex reflection patterns show the need for 3-D surveys to constrain the direction from which reflected energy is returning.

Although most reflection profiling results so far have come from the crust, which is highly reflective relative to the mantle, several speakers discussed sub-crustal reflectors in the mantle. The most dramatic mantle structure imaged by near-vertical reflection seismology so far is the Flannan thrust, a Moho-offsetting fault north-west of Scotland, known to penetrate to at least 45 km, or 15 km below the Moho (D. Matthews). An experiment (DRUM: Deep Reflections from the Upper Mantle) to be conducted later this year, using long recording times, will have the potential to trace this structure, and to search for others, down to 180 km depth.

Sub-crustal structural complexity is also suggested by wide-angle reflections and refractions showing Moho offsets, or Moho doubling, beneath some Tibetan sutures and beneath the North Pyrenean fault (A. Hirn).

Many of the data shown were collected in programs for hydrocarbon and mineral exploration, nuclear waste disposal and earthquake fault hazard reduction, as well as for academic research. J. Oliver (Cornell University) described a plan for worldwide cooperation in undertaking a comprehensive reconnaissance of the earth's continental crust which might collect 200,000 km of deep seismic reflection profiles in a 20 year period. Although sounding impressive, this is in total only one-eighth of the mileage collected by the petroleum industry in a single year. In the United States, COCORP, now in its tenth year, has acquired nearly 6,000 km of crustal reflection data throughout the continent and there are more recent programmes including those of the United States Geological Survey (discussed by R. Hamilton), Virginia Polytechnic Institute (J. Costain), University of Wyoming (S. Smithson) and CALCRUST (P. Malin, University of California, Santa Barbara).

Programmes outside the United States include the Canadian LITHOPROBE (A. Green, Department of Energy, Mines and Resources) on the Quebec Appalachians and Vancouver Island, British Columbia; BIRPS (D. Matthews) which has recorded over 3,000 km of marine data circumscribing Great Britain; the Deutches Kontinentales Reflexions Program of Germany (DEKORP; R. Meissner, Kiel Institut für Geophysik); the French Etude Continentale et Océanique par Réflexion et Réfraction Sismique (ECORS; C. Bois, Institut Francais du Pétrole); the Australian continental reflection programme (F. Moss, Bureau of Mineral Resources) and others in New Zealand, China, India, Hungary, Czechoslovakia, Switzerland, Italy and Antarctica. Many of these groups have plans to expand their programmes considerably, and thus the global initiative outlined by Oliver should be attainable. ☐

Gene expression

Regulation by anti-sense RNA

from Andrew Travers

THE ability of two complementary strands of RNA to form a stable duplex offers a potentially powerful mode of regulating the biological function of RNA molecules. Thus the normal RNA transcript of a gene could be rendered inactive were it to form a duplex with an 'anti-sense' RNA transcript from part of the same DNA. The past year has produced some good examples of how bacteria employ such a form of control; moreover, the experimental manipulation of gene expression by double-stranded RNA in eukaryotic cells has recently been described.

In prokaryotes, a classic example of this type of control is the regulation of DNA replication of the plasmid ColE1. In this case, a short anti-sense transcript is believed to form a RNA–RNA duplex with the 5′ end of the replication primer and as a consequence to inhibit replication (Tomizawa, J. & Itoh, T. *Proc. natn. Acad. Sci. U.S.A.* **78**, 1981; Lacatena, R.M. & Cesareni, G. *Nature* **294**, 623; 1981). Mutations affecting either the structure or the amount of anti-sense RNA affect both copy number and plasmid incompatibility.

One example in the control of bacterial translation is the regulation of Tn*10* transposase production (Simons, R.W. & Kleckner, N. *Cell* **34**, 683; 1983). The discovery stemmed from the observation that the presence of a multicopy plasmid containing the insertion element IS*10* inhibits *in trans* transposition of a single-copy chromosomal Tn*10* element. IS*10* is itself essential for Tn*10* activity, providing the functions necessary for Tn*10* transposition. Simons and Kleckner found that they could delete all but 75 base pairs (bp) of the transposase-coding region of IS*10* and still retain multicopy inhibition, showing that the phenomenon does not require intact transposase protein. Intriguingly, the portion of the transposase gene required contains a promoter which directs transcription in the opposite direction to the transposase gene, producing a RNA molecule which overlaps and is complementary to 36 bases at the 5′ end of transposase mRNA. To determine the target of inhibition, Simons and Kleckner constructed two sets of IS*10*–*lacZ* fusions; in one set, the amino (5′)-terminal portion of the transposase gene with its cognate promoter was fused in frame to an appropriately engineered *β*-galactosidase gene; in the second set, an intact *lacZ* gene was fused to transposase promoter. Multicopy IS*10*-containing plasmids reduced expression of the fusion protein by more than 10-fold but that of the intact *lacZ* gene by less than 2-fold. Assuming that transcription originated from the transposase promoter in both cases, this result strongly suggests that regulation of transposase expression is exerted primarily by modulating translation and not transcription.

A similar situation has been described for the natural regulation of the production of the outer membrane protein encoded by the *ompF* gene (Mizuno, T. *et al. Proc. natn. Acad. Sci. U.S.A.* **81**, 1966; 1984). This protein is one of two major outer membrane proteins of *Escherichia coli* that serve as diffusion pores for small hydrophilic molecules. The total amount of these two proteins, OmpF and OmpC, remains constant but the proportion of the two varies, depending on the osmolarity of the medium. While characterizing the promoter of the *ompC* gene, Mizuno and his colleagues observed that a DNA fragment upstream of the promoter inhibited the production of OmpF protein when *ompF*$^+$ cells were transformed with a multicopy plasmid containing the fragment. They discovered that this DNA fragment encoded a small 174 base RNA, termed mic RNA (mRNA-interfering complementary RNA), which was transcribed in the opposite direction to the *ompC* gene. This RNA contains no open reading frames preceded by a ribosome-binding site and so is unlikely to encode a protein. It does, however, have extensive homology with the 5′ end of *ompF* mRNA, suggesting that the small RNA could form a stable hybrid with *ompF* mRNA. Since the region of homology includes the ribosome-binding site for *ompF* translation the obvious possibility is, again, that hybrid formation between the two RNA species inhibits translation initiation. A further characteristic of potential biological significance is the coordinate regulation of the *ompC* and mic RNA species which could provide an efficient mechanism for maintaining a constant total amount of OmpF and OmpC proteins.

For neither IS*10* transposase nor *ompF* protein production has the presence of a RNA–RNA duplex been directly demonstrated. Nevertheless, the fact that anti-sense RNA molecules can inhibit gene expression has been confirmed by engineering the production of such molecules for other genes. Coleman *et al.* (*Cell* **37**, 429; 1984) constructed plasmids that produce small RNA molecules complementary to the 5′ ends of the mRNA either for *E. coli* lipoprotein or for two other outer membrane proteins, OmpA and OmpC. In all cases expression of these anti-sense RNA species resulted in a substantial inhibition of expression of the target mRNA species. Significantly, anti-sense lipoprotein RNA also reduced expression of *ompC* mRNA and vice versa, a phenomenon consistent with the extensive homology between the 5′ regions of the two mRNA species.

The ability of anti-sense RNA to inhibit gene expression has been shown to be applicable to eukaryotes. Izant and Weintraub (*Cell* **36**, 1007; 1984) constructed a plasmid so that a promoter directed the transcription of a RNA complementary to the normal thymidine kinase (TK) transcript. When such plasmids together with a plasmid containing a normally expressed TK gene were injected into mutant mouse L cells that lacked TK, it was observed that the presence of the 'complementary' gene substantially reduced expression from the normal plasmid.

The extent to which this novel form of regulation of gene expression is utilized naturally in prokaryotes and eukaryotes remains to be established. Clearly, however, the potential for manipulating gene expression artificially by this mechanism is substantial and well worth exploiting. ☐

Sedimentology

Control of dolomite formation

from M. Kastner

A PAPER on page 450 of this issue of *Nature* by Guanatilaka *et al.* describes a recent dolomite $[CaMg(CO_3)_2]$ formation in the subtidal zone of a shallow hypersaline lagoon in southern Kuwait[1]. The finding is of interest not only because it provides further insight into the mechanism of dolomite formation, but also because it has economic implications, dolomite being an important hydrocarbon reservoir, a host-rock for base-metals and associated with evaporites.

Dolomite, one of the three most common sedimentary carbonate minerals, has long perplexed sedimentologists, for two reasons. The first is that there are marked irregularities in its distribution with time. Thus, dolomite is a common, extensive and widespread rock-forming mineral in ancient sediments, in particular in late Precambrian and Palaeozoic times, but it is rather scarce in the Holocene. Between the Jurassic and Cretaceous the ratio of dolomitite (sedimentary rock composed essentially of dolomite) to limestone decreases rapidly and strikingly. Early explanations put forward for the scarcity of Holocene dolomitites were changes in the nature of plate tectonics, correlation with extensive shelf seas, and changes in the magnesium concentration in seawater (for example, refs 2–4), but none has proved satisfactory. The second puzzling aspect of dolomite distribution is that it seems to violate the laws of thermodynamics. Dolomite is the thermodynamically stable carbonate mineral in seawater; why, then, is it relatively scarce in the widespread Holocene marine carbonate sediments?

In the late 1950s and early 1960s several small deposits of Holocene penecontemporaneous dolomites were discovered in marine marginal, mostly supratidal, environments. Their location suggested that dolomite formation requires a molar Mg^{2+}/Ca^{2+} ratio higher than that of seawater (5.3). This theory dominated the literature until five years ago, since when dolomite has been discovered as an important constituent of many modern marine organic-rich sediments, for example, in the Gulf of California, the California borderlands, the shelf off Peru, the Japan trench and the Cariaco Basin off the coast of Venezuela. In the Gulf of California, dolomite forms actively from marine pore fluids with a molar Mg^{2+}/Ca^{2+} ratio of 3.0 (see, for example, ref. 5). Various new models of dolomitization have been proposed[6-8].

Recent experimental work[9,10] shows that the essential condition for dolomite formation is not a high Mg^{2+}/Ca^{2+} ratio, but a low concentration of sulphate ions. Sulphate ions are a major inhibitor of dolomitization of calcite and, to a significantly lesser extent, of aragonite. Mg^{2+}/Ca^{2+} ratios greater than about 0.7 favour dolomitization, but are not thermodynamically required at surface to near-surface temperatures and pressures. Marine sites conducive to dolomite formation are therefore those where dissolved sulphate concentrations are low. The most effective processes of sulphate removal from, or its dilution in, marine pore fluids are microbial sulphate reduction in organic-rich sediments and mixing of seawater with large volumes of freshwater. The high (28 millimoles) dissolved sulphate content of seawater also explains the scarcity of dolomite in thermodynamically highly-favourable environments, for example, in open marine carbonates. Other low-sulphate environments favouring the transformation of $CaCO_3$ into dolomite are $CaCO_3$-rich sediments or rocks exposed on land or within supratidal zones through which freshwater or a mixture of fresh- and seawater circulates, and chalks and limestones through which sulphidic hydrothermal mineralization solutions circulate.

The paper by Gunatilaka *et al*[1] is an important new study of Recent dolomite formation. On the basis of petrographical studies and chemical analyses of pore fluids, the authors suggest that dolomitization of micritic aragonite is promoted by a combination of partial bacterial reduction of sulphate dissolved in pore fluid and occasional near-schizohaline conditions through seasonal rainfall.

What is still puzzling is the paucity of dolomitites formed during the last 100–200 million years relative to their abundance in older sediments. It might be related to changes in the depositional environments of calcareous sediments, and hence to an increase of the calcite/aragonite ratio of the original calcareous sediments following the appearance of coccolithophoroids and foraminifers. On the other hand, the apparent abundance of Archaean dolomitites might indicate that the content of sulphate dissolved in the early oceans was relatively low. ☐

Astronomy

Meteorites from Mars

[illegible]

from David W. Hughes

MUSEUMS around the world have about 2,500 meteorites in their collections. Where have they all come from? Various origins have been proposed, including the Moon, Mars and asteroids. In a recent paper, G.W. Wetherill of the Carnegie Institution of Washington examines the transport of meteoritic material from Mars to Earth.

Meteorites originate as parts of much larger parent bodies, which formed by a process of condensation and accretion, mixing, depletion, melting and loss of volatiles in the primordial Solar System nebula. The process was completed very quickly, about 4.6 × 10^9 years ago. Over the lifetime of the Solar System, the parent bodies have collided, producing fragments which are the meteorite precursors. The diversity of meteorite types suggests they are derived from about fifty parents which themselves differed in composition as a result of the different temperatures and pressures in the various regions of the primordial nebula. Once freed from their parents, the meteorites were exposed to cosmic-ray bombardment, which produced tracks of radiation-damaged material. Analysis of these tracks indicates that the parent-body collisions occurred typically 50 million years ago for the stony meteorites and 1,000 million years ago for the iron meteorites.

As their exposure ages are so short, some meteorite parents should still exist and be an observable class of celestial objects. Possible candidates are the Apollo and Amor asteroids. Alternatively, meteorites may be the debris of disintegrating cometary nuclei or they may have been ejected from Mars, Mercury and the Moon — the major negligible-atmosphere members of the inner Solar System.

Öpik predicted that only 0.2 per cent of meteorites were of lunar origin and suggested that even fewer would come from Mars (*Adv. Astr. Astrophys.* **4**, 301; 1966). Interest in the possibility of a martian origin for meteorites has recently been renewed, however, on account of three meteorite classes, the shergottites, chassignites and nakhlites. Their isotopic composition indicates that they crystallized as recently as 0.18–1.3 × 10^9 years ago. Even more unusual, they have a geochemical and petrological affinity to the rocks of the Earth's mantle. One shergottite, Elephant Morain, has trapped rare gases and nitrogen resembling the composition of the martian atmosphere.

Impact craters are being produced in the surfaces of all inner Solar System planets, including Mars. Crater-forming projectiles hit the planet at the rate of about 10^9 yr^{-1}. This produces about 10^{11} g of ejecta, most of which is melted, vaporized or pulverized and returns to the planetary surface.

In his recent paper (*Meteoritics* **19**, 1; 1984), Wetherill considers two models, for the transport of meteoritic material from Mars to Earth. In the large-body one, fragments larger than 15 m in diameter were ejected from Mars about 180 Myr ago, the shock metamorphism accompanying this ejection setting the isotopic dating clock. These bodies were then broken up by collisions with small asteroids and the fragments exposed to cosmic rays. The fragments subsequently hit Earth. In the small-body model, rocks smaller than 1 m are ejected from Mars and exposed to cosmic rays immediately after ejection. The major difference between the two models is the percentage of material that can be accelerated to greater than the martian escape velocity. Calculations show that only 0.03 per cent survives in the small-body case whereas a more unrealistic 0.4 per cent is predicted in the large-body model. Theoretical work on crater formation also indicates that only small bodies and those lying very near the planary surface will survive unaltered by the ejection process.

The orbits of the ejected bodies have relatively low eccentricities and inclinations and can exist, on average, between 5×10^6 and 100×10^6 years (depending on aphelion distance) before being hit by another minor body in the Solar System and broken up. Calculations show that of all the material that will hit the Earth from a specific martian event, 36 per cent will do so within 10^7 years. In the favoured small-body model, Wetherill suggests that the cosmic-ray exposure ages of the meteorites are equivalent to the transit time between Mars and Earth. The much longer isotopic age represents the time interval between the present day and the time of production of the specific region of Mars' surface that suffered the impact.

Similar calculations were made for Mercury ejector and it was found that 100 times fewer Mercury meteorites would finally hit the Earth.

What remains to be explained is the ratio between martian and lunar meteorites. The shergottite–nakhlite–chassignite class of meteorites represent 8 of the 2,000 distinct recovered stony meteorites. Only one certain lunar meteorite has been found, a 31 g rock found in the Allan Hills region of Antarctica and known as ALHA 81005. (There are two other 'possibles', both found by the Japanese near the Yamato Mountains in Antarctica.) Other things being equal, theory predicts that the influx of lunar meteorites will be at least several hundred times greater than that from Mars. By contrast, observations indicate that it is smaller by a factor of around 3. A possible explanation is that the orbital dynamics mitigates against lunar meteorites. More unlikely is the suggestion that it is due to a statistical quirk, there having been no large lunar cratering events for the last 10^5 years or more. Another possibility is that there is some special characteristic of the martian surface, the presence of volatiles for example, that facilitates the acceleration of impact-generated fragments to very high velocity.

Whatever the outcome, the importance of meteorites is obvious. The museums of the world contain about 200 tonnes of meteoritic material, of which 90 g are thought to come from the Moon, 70 kg from Mars and the rest from asteroids. Unfortunately, it seems that the only rigorous way of checking the martian origin is to go there and see. ☐

Ecology

Forest history from pollen

from Peter D. Moore

POLLEN analysis has proved a useful tool for documenting vegetational changes over thousands of years. Carried out on a regional scale, with information collected from sites, such as large lakes and mires that have been carefully selected such that local vegetational events have little impact and local noise is minimal, the technique has supplied important information on climatic history[1]. To the ecologist, however, it is often the very local events that are of interest. Thus he will tend to choose small ponds, peat deposits and even organic humus layers accumulating on forest floors which receive their pollen input from the local vegetation canopy and in which regional changes in vegetation may be masked by the local flora. Such sites can provide a valuable record of local vegetational history and have recently been exploited for this purpose in many parts of the world.

Bradshaw has shown that in a forest, most pollen does not travel more than 20-30 m (ref.2), and recently, with the help of Jacobson, he has constructed a model relating the origin of pollen components to the diameter of the receptor site[3]. In a small 50 m diameter site, for example, 60–70 per cent of the pollen input is immediately local in origin.

The use of mor humus layers was pioneered in Denmark by Iversen[4,5], who found it a particularly useful technique for the detection of the impact of man on woodlands. His conclusion that *Ilex aquifolium*, holly, had been greatly favoured by man's modification of the Danish forests received further support from work on mor humus layers in the Netherlands by Stockmar[6]. This type of deposit has also proved useful for tracing the history of species that have limited powers of pollen dispersion and that are poorly represented in larger sites. Birks has shown that lime, *Tilia*, a tree which is known to have very local pollen deposition[7], has been abundant in Cumbrian limestone woodland in north-west Britain from about 6,000 years ago[8], while in southern England[9] and in Denmark[10], it declined following man's modification of the forests in AD 600–800 and AD 1650, respectively.

Outside the temperate zone of the Northern Hemisphere, relatively little advantage has been taken so far of the opportunities offered by small sites and mor humus layers. Recently, however, Macphail has done some important work in the wet sclerophyll forests of Tasmania. These forests are dominated by *Eucalyptus* species, often reaching heights of 30–40 m, with a high (20 m) shrub layer, consisting of many species, beneath the canopy. They are found in eastern and south western Australia. Their history is uncertain because of their apparent dependence on fire as a containing factor in succession: in the absence of fire, they may be subject to invasion by temperate rain forest trees. This dependence suggests that they may be a product of human activity and maintained by it.

Macphail has now approached this question by analysing the sediments of a small (8 × 18 m) kettle hole in Tasmanian wet *Eucalyptus* woodland[11]. The sediments have been buried by a landslip and date from the early Holocene (9,000 to 7,000 BP). The changes in the pollen stratigraphy of the site are associated mainly with a sequence of understorey species which can in part be explained in terms of climatic trends. Superimposed, however, is a pattern induced by fires, as indicated by charcoal frequency. A marked increase in fire frequency at about 7,200 BP is associated with Aboriginal activity in the area and this produced a distinct shift in the woodland composition in which the rain forest species, such as *Nothofagus*, which had previously been expanding, were set into decline. The involvement of fire and of man in the persistence of the wet sclerophyll forest is thus confirmed.

One further line of evidence is desirable if such studies are to be exploited to the full, namely the study of modern pollen rain in present-day forest types. In this way the varying properties of pollen production and dispersion in the trees and shrubs of the forest can be compensated for in the interpretation of fossil pollen spectra. Studies of this type in the European forests by Andersen[12] and Bradshaw[2] have proved very informative and one must look forward to the outcome of similar work on small sites in other parts of the world. ☐

Aurora seen in daylight

from Alan Johnstone

THE long-standing question of whether aurora occurs during the day as well as the night has just been answered in a most convincing way. The answer has actually been clear from indirect evidence for many years, because the electrons, which cause the aurora when they cascade into the upper atmosphere, produce many other detectable effects as they excite atmospheric molecules to emit their characteristic light. In fact, aurora occurs all round the magnetic pole in an oval offset towards the nightside. It is there during the summer days of midnight sun as well as during the long weeks of darkness in winter. Sunlight seems to have no influence on the occurrence of aurora. The difficulty until now has been that none of the methods used to detect aurora gives a picture of its structure.

The aurora cannot be seen in daylight because the brightness of scattered light (the blueness of the sky) overwhelms the much fainter light from the aurora. At ultraviolet wavelengths (below 200 nm), however, the background of scattered light is reduced both because the incoming solar radiation is weaker and because the radiation is totally absorbed by the atmosphere before penetrating it or being reflected from it.

Molecules excited by the impact of auroral electrons emit light at ultraviolet wavelengths, notably N_2 in molecular bands between 132.5 and 150 nm, and atomic oxygen with transitions at 130.4 and 135.6 nm. These emissions cannot be seen from the ground because they too are absorbed by the atmosphere. They can, however, be seen from above by instruments carried on satellites because they occur at such a height that the light can escape upwards without much attenuation.

The first auroral images in ultraviolet light, obtained in full sunlight by the American polar-orbiting spacecraft Hilat, have just been published (Meng & Huffman *Geophys. Res. Lett.* **4**, 135; 1984). As the instrument looks down from a height of 820 km it scans a strip 5,000 km long stretching from horizon to horizon across the satellite track. The forward movement of the satellite builds up a picture from a series of parallel lines just as a television tube does. The intensity in a band only 3 nm wide is measured by a spectrometer which covers the range of wavelengths from 110 to 190 nm. This narrow bandwidth improves the signal-to-background ratio when the spectrometer is set on the most prominent features in the auroral spectrum. The proof of the technique is in the picture below which shows a typical auroral structure, familiar from the nightside images.

Now that the restrictions on auroral images imposed by sunlight have been removed, the exciting possibility emerges of obtaining pictures of the aurora simultaneously at both ends of a geomagnetic field line. This would require recording by spectrometers on at least two satellites. A survey of the extent to which the aurora is conjugate would provide a great deal of information about the processes responsible.

Plant science

Molecular studies forge ahead

from John Ingle

EIGHT years and four meetings have passed since the first NATO/FEBS Advanced Study Institute provided a focus for the then fledgling science of plant molecular biology. The progress can honestly be described as dramatic. Research has progressed from the initial problems of DNA isolation and cloning, through nucleotide sequence analysis and vector construction to the use of site-directed mutagenesis for detailed study of regulatory and structural gene sequences. Physiological problems are now routinely addressed via the modulation of gene expression at both RNA and protein levels, and the transfer and efficient expression of tissue-regulated genes is an established fact. The impact and potential of molecular manipulations on the improvement of plants has attracted commercial interest in agricultural opportunities, a point amply illustrated by the strength and vigour of biotechnology company participation at a recent meeting*.

The initial focus of plant molecular biology on the chloroplast has largely continued, producing a detailed analytical description of its genome. Functional characterization of the genome has been less successful, depending largely on the use of heterologous *in vitro* systems, such as *Escherichia coli*. The development of an homologous transcription system and characterization of the RNA polymerase activities responsible for expression of chloroplast genes, together with the identification of chloroplast promoter elements, represents a major advance (W. Gruissem, University of California, Berkeley), but a chloroplast transformation system is still urgently needed.

For nuclear genes a welcome main trend

---

*'Molecular form and function of the plant genome'. NATO Advanced Studies Institute FEBS Advanced Course, 4-14 July, Renesse, The Netherlands.

is the increase in diversity of genes being studied and the improved detail of expression studies. The small subunit of ribulose bisphosphate carboxylase still dominates the field, offering an excellent experimental system for the study of such crucial problems as transport of proteins across membranes, regulation in response to light and expression of individual genes within a gene family. The complexity of gene expression, particularly at the post-transcriptional level, was indicated from a detailed study on the sulphur-rich albumin in pea seeds (T.J.V. Higgins, CSIRO, Canberra). In plants grown in sulphur-deficient conditions, accumulation of albumin is severely reduced and there is a low level of messenger RNA. This is due to destabilization of transcripts, which are synthesized at approximately the same rate as in control plants.

The complexity of the mitochondrial genome far exceeds that of the chloroplast, both in genetic and structural terms (D. Lonsdale, Plant Breeding Institute, Cambridge). The genome consists principally of circular DNA, and a master chromosome of 570 kilobase pairs (kbp) has been described in maize. The presence of several different repeated sequences within this circular molecule can result, however, in dramatic genome rearrangements through recombination, producing a variety of circular mitochondrial chromosomes. Mitochondria also possess small plasmids or episomes, which may be circular or linear. In the case of the linear episomes in the S male sterile cytoplasm, the terminal inverted repeats of the episomes share sequences with the circular chromosome such that recombination results in the linearization and fragmentation of the circular genome. The S-type mitochondrial genome therefore undergoes a dynamic flux between circular and linear chromosomal forms, and it is tempting to give these DNA rearrangements functional signficance, such as control of the male sterile phenotype.

Functional modification of the genome appears to be necessary for differentiation of nitrogen-fixing heterocysts in *Anabaena* (R. Haselkorn, University of Chicago). In vegetative non-fixing cells the *nif K* and *nif D* genes are separated by 10 kbp. This DNA is excised during the early stages of heterocyst differentiation, thereby bringing the genes into close proximity, and remains in the cell as a 10 kbp circle. These examples of mitochondrial DNA and *nif* DNA rearrangements, together with the genomic splicing mechanisms associated with immunoglobulin expression in animals, suggest that genome rearrangement may be a general feature of differentiation and development.

Commercial interest in improving plant varieties by genetic manipulation was well illustrated by excellent contributions on herbicide resistance. The 32,000-molecular weight ubiquinone-binding protein of photosystem II in the chloroplast was probably the most discussed protein of the meeting. A single amino acid change confers resistance to triazine herbicides, but the lack of a chloroplast transformation system has so far prevented its exploitation, except by cell fusion technology. The biochemical mechanisms involved in resistance to other herbicides, such as glutathione-*S*-transferase for chloroacetamides or triazines, 3-phosphoshikimate 1-carboxyvinyltransferase for glyphosate or acetolactate synthase for sulphonylureas, have been elucidated (R. Fraley, Monsanto, St Louis; L. Comai, Calgene, Davis; and S.C. Falco, Du Pont, Wilmington, respectively), and genes conferring resistance have been isolated and characterized from plants, bacteria and yeast. Some of these genes have been transferred to plants, but so far no resistant plants have been reported.

The successful transfer of the phaseolin gene from *Phaseolus* to sunflower has been followed up by transfer into tobacco. Regenerated tobacco plants have given the first clear indication of developmental regulation of a transferred gene since phaseolin, a seed storage protein, was produced in tobacco seeds but not in leaves, and the single copy of the gene appeared to be expressed to a similar level to that in *Phaseolus* seed (T.C. Hall, Agrigenetics, Madison). These results, together with a much improved 'leaf disk dip' for transformation of plant tissue (R. Fraley, Monsanto, St Louis) and the success of monocotyledon transformation by *Agrobacterium tumefaciens* (P. Hooykaas, University of Leiden), fully support the practical potential that has been envisaged for foreign gene expression in agricultural plants. □

Growth factors

The epidermal growth factor receptor gene and its product

from Tony Hunter

THE establishment of a direct mechanistic link between growth control and tumorigenesis has been a long-standing pipedream, but, within the last year, two such connections have been made. In both cases the connection is between the product of a known viral oncogene and a known cellular growth factor or its receptor. Late last year, the product of the v-*sis* gene was found to be closely related to platelet-derived growth factor (PDGF); and more recently, a remarkable similarity has been demonstrated between the product of the v-*erb*-B oncogene of avian erythroblastosis virus (AEV) and the receptor for epidermal growth factor (EGF)[1]. This homology and some partial protein sequence data for the EGF receptor have now enabled three groups to isolate cDNA clones for the EGF receptor mRNA and thus extend the characterization of the EGF receptor[2-4].

All three groups used as their primary source of EGF receptor mRNA the A431 human carcinoma cell line, which expresses 10–50 times more EGF receptors on its surface than most other cell lines do. The cloning of the EGF receptor mRNA has now helped to elucidate the normal structure and function of the receptor, its relationship to the v-*erb*-B oncogene product and several abnormalities associated with its expression in A431 cells.

EGF receptor protein structure

The EGF receptor was already known to be a 170,000–180,000 molecular weight (170–180K) glycoprotein with an intrinsic tyrosine-specific protein kinase which is stimulated upon binding EGF. From the primary amino acid sequence predicted from the nucleotide sequences of cDNA clones covering the entire coding region, the following picture of the EGF receptor now emerges (ref. 2 and see the figure). A signal peptide of 24 amino acids is cleaved from a precursor to yield a mature protein of 1,186 amino acids. The receptor can be divided figuratively into two parts: an NH_2-terminal region of 621 amino acids and a COOH-terminal domain of 542 amino acids, separated by a run of 26 preponderantly hydrophobic amino acids, which has been proposed to form a membrane-spanning domain[2,3]. The putative transmembrane domain is bounded on the cytoplasmic side by an extremely basic (9/15 residues) sequence, a feature which is common to many membrane-spanning segments.

From its sequence one would deduce that the N-terminal region is the external EGF-binding domain; it contains 51 cysteine residues, many of which must be involved in disulphide bonds, and 12 potential glycosylation sites, a number which fits well with the experimentally determined number of oligosaccharide chains[5]. The cysteines are clustered in two regions, each of about 170 amino acids (positions 132–313 and 446–612), which show similarities in the spacing of individual cysteines[2]. These might form a two-lobed structure with an EGF-binding cleft. This 'duplicated' structure could be involved in ligand-mediated receptor oligomerization.

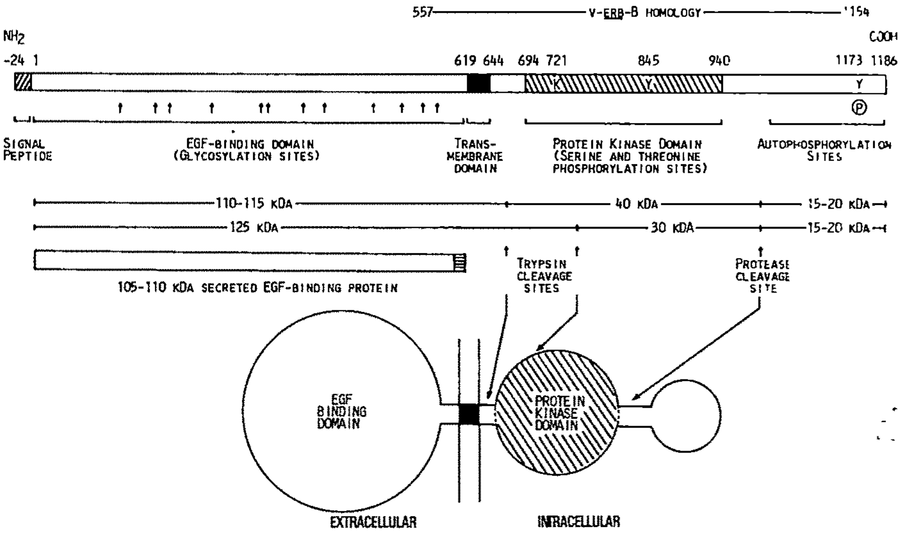
The C-terminal region has strong sequence homology with the predicted v-*erb*-B gene product over a stretch of 250 amino acids starting at residue 694, about 50 amino acids from the proposed transmembrane domain. This region also shows homology to the catalytic domains of other protein kinases including the members of the *src* gene family of tyrosine-phosphorylating protein kinases. Thus it seems likely that this region comprises a cytoplasmic domain responsible for the tyrosine protein kinase activity of the receptor. The final 240 amino acids at the C-terminus of the EGF receptor show no homology with known proteins.

Gene structure and expression

Based on the sizes of the restriction enzyme fragments in placental DNA homologous with the various cDNA clones it can be deduced that the human EGF receptor gene is a large gene, greater than 50 kilobases (kb) in size[2]. All three groups find that the receptor gene is amplified in A431 cells, from 3- to 100-fold depending on the clone of cells analysed[2,4,6]. The amplification could in principle be responsible for the high level of EGF receptors found on these cells. Indeed, there does appear to be some correlation between the degree of amplification and the expression of EGF receptor both at the mRNA level and at the protein level[3,4]. The amplification may be associated with a translocation involving chromosome 7, to which the EGF receptor gene has been mapped[7,8], although the amplification of the gene is greater than that expected from the total number of copies of both normal and translocated chromosome 7 found in A431 cells[9]. The amplification does not seem to be a direct consequence of the translocation event since cells lacking the translocated chromosome have an amplified EGF receptor gene[4]. The structure of the amplified genes is similar to that of the normal gene, although there are minor differences[2,3].

The EGF receptor gene is expressed in the form of at least two mRNAs, with sizes of about 10 and 6 kb (refs 2–4). The exact relationship between these mRNAs is not yet known. The 6 kb RNA predominates but the ratio of the two RNAs differs between cell types. The structures of the overlapping cDNA clones[2] prove that the 6 kb RNA can encode the EGF receptor, but whether this is the case for the 10 kb RNA is uncertain. The two RNAs could well have similar 5′ ends and differ through virtue of alternate splicing pathways or poly(A) addition sites such that the 10 kb RNA carries a longer 3′-untranslated region.

In A431 cells a third EGF receptor-related mRNA is detected with a size of about 3 kb. The origin of this RNA is unclear but it is more common than the 6 kb RNA and might therefore arise from the amplified copies of the receptor gene, possibly as the result of an abnormal splicing event or some minor change in gene structure. This small RNA is all the more intriguing because its sequence corresponds to just the N-terminal half of the EGF receptor, including most of the EGF-binding region and a tail of 18 amino acids from an unknown source. Because the predicted protein lacks the transmembrane domain, it could well be secreted; and in fact, A431 cells have been observed to secrete just such an EGF-binding activity in the form of a 105–110K glycoprotein[5,10]. So far the 3 kb RNA and secreted protein have been detected only in A431 cells, and it will be interesting to see whether they are made by any normal cell type.



Relationship between the v-*erb*B gene (top), EGF receptor gene (middle) and EGF receptor protein (bottom), shown in linear form and as it might be organized in spanning the membrane of a cell.

Does the more extensive knowledge of the EGF receptor gene allow us to decide whether it is the c-*erb*-B gene as has been proposed? When amino acids 557–1,154 of the EGF receptor are compared with the v-*erb*-B gene product an overall homology of about 85 per cent is found, which rises to a striking 97 per cent homology in the protein kinase domain. The main difficulty in deciding on this basis whether the two genes are identical is that one is comparing the human EGF receptor with a chicken-derived oncogene potentially carrying point mutations. Human sequences homologous to the v-*erb*-B gene have been cloned[11]. They presumably arose from the c-*erb*-B gene, but no nucleotide sequence data are available to show whether it is a genuine identity rather than a close relationship. Chromosome-mapping results are consistent with the human c-*erb*-B-related sequence (chromosome 7 between 7p13 and 7q22)[12] and the human EGF receptor gene (chromosome 7 between 7p22 and 7qter)[7,8] being one and the same. On balance, therefore, it seems likely that the c-*erb*-B gene is the EGF receptor gene, but it is still formally possible that there are two related genes on chromosome 7 with homology in the protein kinase domain.

EGF receptor protein kinase

What is the evidence that the protein kinase activity of the receptor is located where the primary sequence predicts? There are several reports indicating that a fragment of 15–20K can be clipped proteolytically from the cytoplasmic domain of the EGF receptor leaving a 150K fragment which retains EGF-stimulated protein kinase activity. In the light of the sequence data, the 15–20 K fragment probably corresponds to the C-terminal region, which may be connected to the protein kinase domain by an exposed linker accessible to proteases. More extensive tryptic proteolysis of the purified receptor either in solution or bound to antibody gives rise to 30–40K and 110–125K fragments[5,13,14], presumably arising from the 150K C-terminally truncated receptor. The 110–125K fragment contains the EGF-binding site and all of the glycosyl side chains[13]. A report in this issue of *Nature* by Basu *et al.*[14] shows that the 40K fragment generated by trypsin treatment of receptor in solution retains about 30 per cent of the tyrosine protein kinase activity of the intact receptor. By contrast, the 30K fragment, which is the main species liberated by trypsin from EGF receptor bound to antibody, seems to lack tyrosine kinase activity[13]. The existence of alternate protease cleavage patterns for receptor in solution and bound to antibody might explain this difference.

The 40K fragment can both 'autophosphorylate' and phosphorylate exogenous substrates, but this activity is no longer regulated by EGF, nor does the fragment bind EGF[14]. The 40K fragment can be modified by the ATP analogue, 5′-*p*-fluorosulphonylbenzoyladenosine (FSBA), concomitant with the loss of protein kinase activity, as had previously been reported for the holoreceptor. In the case of the archetypal tyrosine protein kinase, $pp60^{v\text{-}src}$, FSBA inactivation is due to covalent modification of lysine 295 (ref. 15). This lysine is 16 residues downstream of the Gly-X-Gly-X-X-Gly sequence believed to be involved in nucleotide binding. Lysine 295 of $pp60^{v\text{-}src}$ is homologous to the ATP-binding lysine 71 in the cyclic AMP-dependent protein kinase and would correspond to lysine 721 in the EGF receptor or lysine 165 in the v-*erb*-B protein, both of which are 21 residues downstream of a Gly-X-Gly-X-X-Gly sequence. The likely location of the ATP-binding site, together with the results of Basu *et al.*, provide strong experimental support for the predicted location of the protein kinase domain within the EGF receptor. It is interesting to note that two of the retroviral tyrosine protein kinases can be cleaved by proteases to generate 30–40K fragments which retain tyrosine protein kinase activity[16,17]. Perhaps all tyrosine protein kinases which are members of the *src* family will prove to have such a protease-resistant catalytic domain.

Receptor phosphorylation

The sites of phosphorylation in the EGF receptor are of obvious interest because of intimations that its protein kinase activity may be regulated by phosphorylation. Based on sequence studies of phosphopeptides, Downward *et al.* [18] report in this issue of *Nature* that at least three out of four major 'autophosphorylation' sites are in the C-terminal 15–20K tail, suggesting an attractive model in which the C-terminal domain, by virtue of a flexible connection to the rest of the molecule, might be able to fold over and interact with the catalytic site.

Tyrosine 1,173, one of the autophosphorylation sites, corresponds to the only tyrosine detectably phosphorylated in intact cells in response to EGF[18,19]. Occupation of this site correlates with increased phosphotransferase activity towards exogenous substrates, perhaps because it results in the displacement of the C-terminal domain from the active site, thus allowing access to exogenous substrates. Two other autophosphorylation sites have been mapped close to the C-terminus (residues 1,068 and 1,148), but since these are only weakly phosphorylated in the cell, their significance is uncertain.

The C-terminal region of the EGF receptor, containing tyrosine 1,173, is missing from the v-*erb*-B genes of both strains of AEV. It is not clear whether the loss of this potentially regulatory region is a *sine qua non* for the oncogenic activation of the c-*erb*-B gene or whether it is simply a consequence of the recombination mechanism by which this gene was coopted. Examination of the structure of c-*erb*-B genes which have been activated by viral long-terminal-repeat promoter insertion[20] may well provide the answer to this question.

The retroviral tyrosine protein kinases all have a site of tyrosine phosphorylation in the catalytic domain, which can be autophosphorylated in vitro. In pp60$^{v\text{-}src}$ it is tyrosine 416, which aligns with an homologous tyrosine that is phosphorylated in the other retroviral tyrosine kinases. Tyrosine 416 of pp60$^{v\text{-}src}$ is homologous to tyrosine 845 within the protein kinase domain of the EGF receptor, yet apparently tyrosine 845 is not phosphorylated to a measurable extent in intact cells. The effect of this tyrosine phosphorylation on the activity of the retroviral protein kinases is variable, being minimal in the case of pp60$^{v\text{-}src}$ (ref.21), but of greater consequence for P140$^{gag\text{-}fps}$ (ref.22). Regardless of the functional significance of this phosphorylation it is somewhat surprising that autophosphorylation of tyrosine 845 in the EGF receptor is not observed.

In addition to tyrosine 1,173, the EGF receptor also has several sites of threonine and serine phosphorylation which are localized predominantly in the 30–40K proteolytic fragments and thus lie in the protein kinase domain[13]. The provenance of the protein kinases responsible for these phosphorylations is uncertain, nor is it known whether these modifications modulate receptor function. The EGF receptor can be phosphorylated *in vitro* by the cyclic AMP-dependent protein kinase[23,24], but this does not appear to alter its tyrosine protein kinase activity and there is no evidence that it is physiologically significant.

Two recent reports have indicated that the EGF receptor is also a substrate for the Ca^{2+}/phospholipid-dependent diacylglycerol-activated serine/threonine-specific protein kinase, C-kinase[25,26]. C-kinase appears to be the major receptor for the phorbol ester tumour promoters, such as 12-*O*-tetradecanoylphorbol-13 acetate (TPA), being activated upon binding phorbol esters. TPA enhances serine and threonine phosphorylation of EGF receptor in A431 cells, and at least one new site of threonine phosphorylation is evident[25,26]. This site is also phosphorylated when purified EGF receptor is incubated with purified C-kinase[25]. C-kinase-mediated phosphorylation of the EGF receptor in A431 cells leads to a diminished ability of EGF to stimulate its tyrosine protein kinase activity[25,27]. It is therefore intriguing that under some circumstances the same site is phosphorylated following EGF treatment[26]. Since EGF is known to increase the turnover of phosphatidylinositol, leading to formation of diacylglycerol, this effect of EGF may be mediated indirectly through an activation of C-kinase resulting from increased diacylglycerol production. Possibly the normal role of this phosphorylation is to act as a feedback mechanism to attenuate the response of the EGF receptor. Increased phosphatidylinositol turnover is a rather general effect of mitogen treatment, so it will be interesting to find out whether similar mechanisms exist for other growth factor receptors.

In fibroblasts TPA treatment leads to decreased EGF binding due to changes in either binding affinity or receptor number, while in A431 cells a class of very high-affinity receptors is lost. This effect, together with that on the tyrosine protein kinase activity of the receptor, indicates that phosphorylation of the cytoplasmic domain of the receptor by C-kinase can modulate communication between the extracellular EGF-binding domain and the protein kinase domain. From our own data, reported in this issue of *Nature*[28], the major site of threonine phosphorylation for C-kinase in the A431 cell EGF receptor is threonine 654, which lies in the basic region nine residues from the cytoplasmic end of the proposed transmembrane domain. Thus this threonine is situated between the extracellular domain and the protein kinase domain in an ideal position to affect interaction of the two domains.

An important issue raised by our new knowledge of the structure of the EGF receptor is how EGF binding transmits signals to the cytoplasm. It is not clear whether a protein chain which only traverses the plasma membrane once could transmit an allosteric signal. Potentially, oligomerization of the receptor in the membrane could be required, although one has to explain how EGF stimulates the phosphotransferase activity of the EGF receptor in solution. Another consideration is that the v-*erb*-B gene product, which lacks the majority of the extracellular domain, does not display overt tyrosine protein kinase activity. This implies that simple removal of the regulatory domain does not lead to constitutive activation of the catalytic domain. A comparison of the structures of the other receptors with inducible tyrosine protein kinase activities, such as the PDGF and insulin receptors, may give us a clue to the mechanism of signal transduction. The cloning and sequencing of these receptors is eagerly awaited. ☐

Malignant cell lines — why use APUDoma?

SIR — Several investigators have referred to our cell lines, COLO 320 and 321 as APUDomas (meaning "containing amine precursor uptake and decarboxylase activities"). These cell lines were derived from a carcinoma of the colon and are interesting because of their replication of c-*myc* oncogene[1]. Our description[2] of the cell lines included a list of cell products. The detection of several peptide hormones was subsequently interpreted by others as evidence that the cell line should be labelled "APUDoma".

Many diverse malignancies have been "frozen" in a stage of differentiation which results in activation of the genes for one or multiple peptide hormones[3]. There are probably malignant forms of every single kind of cell that could be labelled "APUDoma".

It seems reasonable that cell line designations should not be altered but that unique aspects of the cells should be noted if relevant to the work being described.

Mechanism for heritability of intelligence

SIR — I wish to suggest a partial answer to the important question of what mechanism in the central nervous system may account for the heritability of intelligence[1].

Although we are far from having a generally agreed definition of intelligence, let alone an understanding of the mechanism responsible, I believe that even now we can specify one necessary neurophysiological aspect of the variation in degree of intelligence and show that it has an appreciable degree of genetic determination. Whatever intelligence is, it must require communication, by nerve impulses, among different regions of the brain. These impulses are transmitted along nerve fibres and across synapses with the participation of many different proteins (including enzymes) and other molecules, such as neurotransmitters (which are synthesized by specific enzymes). These 'transmission proteins', like all proteins, are composed of polypeptide chains which are direct gene products.

There is great genetic diversity among humans (within races); half or more of structural gene loci are polymorphic, that is, they have two or more common alleles (genes) at that locus[2]. We consequently expect appreciable genetic variability among individuals for the genes specifying these 'transmission proteins'. In addition to this direct genetic variation in the structure, and hence the activity of these proteins, there is a second kind of genetically specified variation: differences, among normal individuals, in the amount (concentration) of each specific protein. In particular, whenever enzyme concentrations, for example, dopamine-β-hydroxylase and catechol-*O*-methyltransferase (which, respectively, synthesize and metabolize the neurotransmitter noradrenaline) have been studied genetically, they have been found to be under appreciable genetic control[3].

This genetic variability, both in structure and amount of transmission proteins is, of course, heritable from parent to offspring. This variability will affect nerve impulse transmission in the brain to some degree and in a variety of ways, such as in speed and accuracy. It therefore sets limits on information processing rates. Data from mice support this interpretation, directly showing heritability of nerve conduction velocity[4,5] and synaptic transmission time[6]. This genetic control of information processing is, I submit, a sufficient basis for asserting that there is significant genetic determination of variation in human intelligence.

I do not suggest of course, that such a mechanism would operate in isolation. I believe that in all societies, environment (in the broadest sense, beginning prenatally) also has very important effects (positive and negative) on human intelligence.

Atmospheric humidity in the nuclear winter

SIR — Recent calculations[1,2] and discussion of the possibility of a 'nuclear winter' consequent to widespread nuclear war may have ignored an important effect of atmospheric humidity. The nuclear winter is calculated[2] to be severe for wars in the late spring or summer. In those seasons, at most assumed targets the dew point is quite high, usually no less than 55°F (13°C). Soot from urban or forest fires would be produced intimately mixed in this humid air.

In order to reach the "nuclear winter" state this air is chilled. That portion of it which rises to the upper troposphere or higher reaches ambient temperatures when its rise stabilizes, in an hour or less; only on a much longer time scale does solar heating rewarm it. The remaining sooty air is below the warming influence of sunlight, and it cools to the low surface air temperatures calculated for the nuclear winter. In each case the air is cooled to a temperature at which the saturation water vapour pressure is far below the initial vapour content. The resulting condensate efficiently scavenges the soot aerosol, as in the precipitation cleaning of urban smog and the black rain observed after firestorms; precipitation removes both water and soot from the atmosphere.

Scavenging is unavoidable: in nuclear winter calculations the air begins warm and humid and ends cool and dry, a process which must efficiently purge it of its water vapour and aerosols. This effect has been ignored in the published calculations[1,2] because they begin by assuming a distribution of soot in the troposphere, and do not calculate condensation and scavenging. A quantitative understanding will require detailed calculation of rising sooty plumes and of condensation and scavenging both there and in the cooling troposphere.

DNA can be a selfish parasite

SIR — Evans[1] recently pointed out a "fatal flaw" in all evolutionary discussions of selfish or parasitic DNA. The problem, as outlined by Evans, is that any element which imposes *any* cost on its host will be eliminated by natural selection; this selection pressure can be counteracted only by a mechanism for horizontal transfer (presumably virus-like infection of cells) or by a high rate of *de novo* generation of new elements. The latter condition is highly unlikely and the former would imply that parasitic DNA is merely a new label applicable only to conventional viruses. I cannot agree with these conclusions.

I have already explored[2] in some detail the questions raised by Evans and the main conclusion is that parasitic DNAs can potentially spread very rapidly in natural populations despite the fact that they may also have significant negative effects on host fitness. A mechanism of horizontal spread is not necessary provided there is biparental inheritance of host genomes. This criterion is met in all sexually-reproducing, out-breeding higher eukaryotes. Parasitic elements capable of duplicate transposition are able to "colonize" new chromosomes at zygote formation. Thus, the elements can spread to new genomes by a means other than horizontal transfer. The general prediction of this model is that we expect a higher level of such parasites within the genomes of out-breeding higher eukaryotes than within the genomes of asexually reproducing prokaryotes. The experimental evidence is consistent with this prediction.

Other theoretical studies[3-5] have incorporated negative selection into models of selfish DNA and, recently, such a model[6] was applied explictly to the case of transposable P elements in *Drosophila*. P elements have a demonstrable negative effect on host fitness, yet they have spread rapidly within natural populations[7].

In conclusion, I believe that the remarks of Evans[1] are very pertinent to the question of parasitic DNA in some genomes but the situation is less restrictive than he describes for the case of the higher eukaryotes. I would say that parasitic DNA is not only possible but highly probable in these latter organisms. The evolutionary pressures on this DNA would indeed be of the type outlined by Doolittle *et al.*[8].

Primroses and self-fertilization

SIR — Bodmer's recent letter[1] concerning homostyle primroses raises some scientific issues on which we would like to comment. First, he suggests that it is important to explain why the self-fertile homostyle variant is confined to a few English populations; his model of a low rate of self-fertilization and a small viability disadvantage to homostyles[1,2] is intended to provide such an explanation in view of the absence of evidence for the large viability disadvantage of homozygous homostyles postulated by Crosby[3]. There is, however, no direct evidence that the primrose populations containing homostyles are tending towards a stable polymorphic equilibrium, as Crosby and Bodmer assume. As was previously pointed out[4], the polymorphism for homostyles in *Primula vulgaris* is a highly exceptional situation; most species of *Primula* are, of course, distylous and self-incompatible, but there are many in which homostyly has become fixed[5,6]. The same is true of other groups of distylous plants[7,8]. It is thus entirely possible that *P. vulgaris* is merely in a state of transient polymorphism, and that the homostyle variant is on its way to fixation, at least locally[4]. The model of a conflict between the advantage of fertility assurance of a self-fertile form and the disadvantage of inbreeding depression to its progeny can explain why homostyles become established only in some species or in some geographical areas of a species[4,9]; the biogeographic data on the distribution of homostyly are consistent with this model[4,6,8].

Second, Bodmer suggests that the selfing rate of homostyles may vary in time and space, so that our estimate[9] of a value of 0.92 for a single population in 1982 is not necessarily representative. We certainly agree with this, but would like to point out that there are two other independent estimates of the selfing rate for natural populations which give values of 0.93 (refs 10, 11); within the limits of sampling error, these estimates agree. Richards[12] has made clear the difficulties in interpreting Bodmer's low selfing rate estimate[2,13] for garden material, and in extrapolating this to natural populations. (As noted by Crosby[10], this estimate excluded data from a year (1955) in which the selfing rate was apparently unity). The weight of the empirical evidence is, we feel, in favour of a high selfing rate for homostyle primroses in nature.

Herpes simplex transforming fragments

SIR — In the past twelve months, the subject of viral genes involved in immortalization and tumorigenic transformation has been reviewed at least three times in the News and Views section of *Nature*. Every time when reference was made to DNA tumour viruses, it was stated that genetically distinct functions for immortalization and malignant transformation have been demonstrated for two DNA viruses, polyoma virus and adenovirus. Mention was never made of the separable immortalizing and tumorigenic functions that have been identified in the genome of the human DNA virus herpes simplex type 2 (HSV-2).

The first report of escape from senescence and neoplastic transformation of early passage, nonestablished Syrian hamster embryo cells by a defined subgenomic fragment of HSV-2 DNA appeared in the spring of 1980[1]. Last autumn evidence was published[2] for the existence of two separate genetic functions within this defined fragment. One subfragment derived from the 64% left-hand end was shown to cause immortalization, whereas the other subfragment from the 36% right-hand end was demonstrated to cooperate with the left-hand subfragment in mediating tumorigenic transformation. What makes the HSV-2 data especially interesting is that the immortalizing DNA segment contains a region that exhibits homology to an interspersed middle-repetitive DNA sequence in mammalian cells[2,3]. I should like to bring these reports to the attention of *Nature* and its readers.

Chinese sources no guide to Geminga

SIR — Pannekoek, in his study of Ptolemy[1], remarks "In studying the history of astronomy we are not learning something about the stars, but something about the astronomers". This statement is true for the Chinese records as well. The Chinese records are notorious for their inaccuracy and unreliability[2], and modern astronomers have been too keen to identify new sources with ancient recorded phenomena. Kukarkin *et al.*[3] list a good many identifications of ancient Chinese "nova" recordings with modern counterparts, and note that the vast majority of these is unfounded, and many (notably radiosources) are demonstrably wrong.

The reality of a phenomenon chronicled by the Chinese often has to be doubted[2], and the position is always uncertain (a famous example is the wrong position for the Crab nebula[4]). Rather than contribute to the spread of spurious identifications in the literature — once in existence, they die hard — Editors of scientific journals[5] would do well to show more restraint in publicizing such identifications. Bignami *et al.*[6] are justified in mentioning the Chinese record of AD 437; but its identification with Geminga can only be accepted if in addition to the positional coincidence (of necessity inaccurate) a much more precise temporal coincidence is established.

REVIEW ARTICLE

Cellular automata as models of complexity

Stephen Wolfram

The Institute for Advanced Study, Princeton, New Jersey 08510, USA

Natural systems from snowflakes to mollusc shells show a great diversity of complex patterns. The origins of such complexity can be investigated through mathematical models termed 'cellular automata'. Cellular automata consist of many identical components, each simple, but together capable of complex behaviour. They are analysed both as discrete dynamical systems, and as information-processing systems. Here some of their universal features are discussed, and some general principles are suggested.

IT is common in nature to find systems whose overall behaviour is extremely complex, yet whose fundamental component parts are each very simple. The complexity is generated by the cooperative effect of many simple identical components. Much has been discovered about the nature of the components in physical and biological systems; little is known about the mechanisms by which these components act together to give the overall complexity observed. What is now needed is a general mathematical theory to describe the nature and generation of complexity.

Cellular automata are examples of mathematical systems constructed from many identical components, each simple, but together capable of complex behaviour. From their analysis, one may, on the one hand, develop specific models for particular systems, and, on the other hand, hope to abstract general principles applicable to a wide variety of complex systems. Some recent results on cellular automata will now be outlined; more extensive accounts and references may be found in refs 1-4.

Cellular automata

A one-dimensional cellular automaton consists of a line of sites, with each site carrying a value 0 or 1 (or in general $0, \ldots, k-1$). The value a_i of the site at each position i is updated in discrete time steps according to an identical deterministic rule depending on a neighbourhood of sites around it:

$$a_i^{(t+1)} = \phi[a_{i-r}^{(t)}, a_{i-r+1}^{(t)}, \ldots, a_{i+r}^{(t)}] \qquad (1)$$

Even with $k=2$ and $r=1$ or 2, the overall behaviour of cellular automata constructed in this simple way can be extremely complex.

Consider first the patterns generated by cellular automata evolving from simple 'seeds' consisting of a few non-zero sites. Some local rules ϕ give rise to simple behaviour; others produce complicated patterns. An extensive empirical study suggests that the patterns take on four qualitative forms, illustrated in Fig. 1:

(1) disappears with time;
(2) evolves to a fixed finite size;
(3) grows indefinitely at a fixed speed;
(4) grows and contracts irregularly.

Patterns of type 3 are often found to be self-similar or scale invariant. Parts of such patterns, when magnified, are indistinguishable from the whole. The patterns are characterized by a fractal dimension[5]; the value $\log_2 3 = 1.59$ is the most common. Many of the self-similar patterns seen in natural systems may, in fact, be generated by cellular automaton evolution.

Figure 3 shows the evolution of cellular automata from initial states where each site is assigned each of its k possible values with an independent equal probability. Self-organization is seen: ordered structure is generated from these disordered initial states, and in some cases considerable complexity is evident.

Different initial states with a particular cellular automaton rule yield patterns that differ in detail, but are similar in form and statistical properties. Different cellular automaton rules yield very different patterns. An empirical study, nevertheless, suggests that four qualitative classes may be identified, yielding four characteristic limiting forms:

(1) spatially homogeneous state;
(2) sequence of simple stable or periodic structures;
(3) chaotic aperiodic behaviour;
(4) complicated localized structures, some propagating.

All cellular automata within each class, regardless of the details of their construction and evolution rules, exhibit qualitatively similar behaviour. Such universality should make general results on these classes applicable to a wide variety of systems modelled by cellular automata.

Applications

Current mathematical models of natural systems are usually based on differential equations which describe the smooth variation of one parameter as a function of a few others. Cellular automata provide alternative and in some respects complemen-

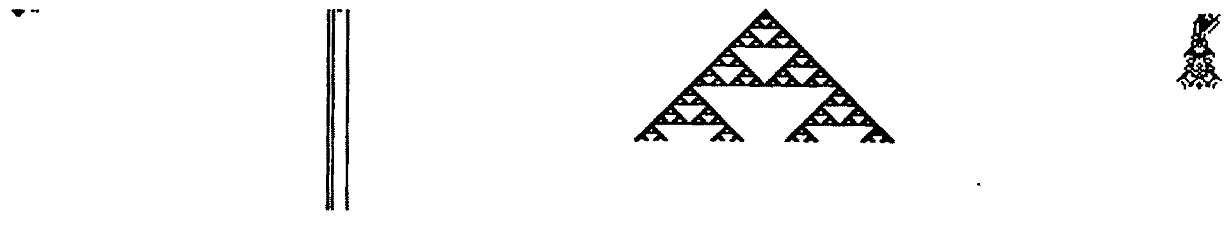

Fig. 1 Classes of patterns generated by the evolution of cellular automata from simple 'seeds'. Successive rows correspond to successive time steps in the cellular automaton evolution. Each site is updated at each time step according to equation (1) by cellular automaton rules that depend on the values of a neighbourhood of sites at the previous time step. Sites with values 0 and 1 are represented by white and black squares, respectively. Despite the simplicity of their construction, patterns of some complexity are seen to be generated. The rules shown exemplify the four classes of behaviour found. (The first three are $k=2$, $r=1$ rules with rule numbers[1] 128, 4 and 126, respectively; the fourth is a $k=2$, $r=2$ rule with totalistic code[2] 52.) In the third case, a self similar pattern is formed.

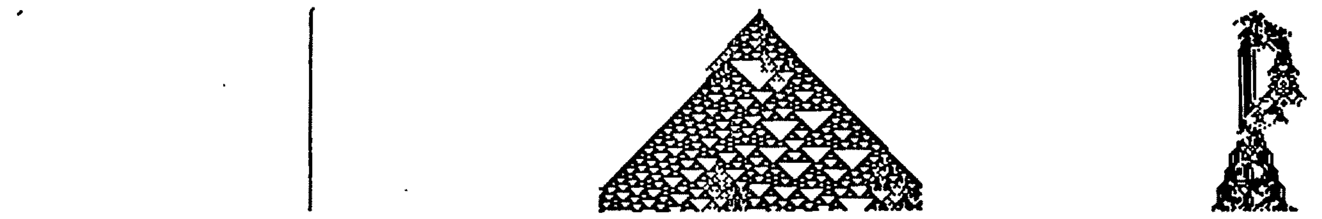

Fig. 2 Evolution of small initial perturbations in cellular automata, as shown by the difference (modulo two) between patterns generated from two disordered initial states differing in the value of a single site. The examples shown illustrate the four classes of behaviour found. Information on changes in the initial state almost always propagates only a finite distance in the first two classes, but may propagate an arbitrary distance in the third and fourth classes.

tary models, describing the discrete evolution of many (identical) components. Models based on cellular automata are typically most appropriate in highly nonlinear regimes of physical systems, and in chemical and biological systems where discrete thresholds occur. Cellular automata are particularly suitable as models when growth inhibition effects are important.

As one example, cellular automata provide global models for the growth of dendritic crystals (such as snowflakes)[6]. Starting from a simple seed, sites with values representing the solid phase are aggregated according to a two-dimensional rule that accounts for the inhibition of growth near newly-aggregated sites, resulting in a fractal pattern of growth. Nonlinear chemical reaction–diffusion systems give another example[7,8]: a simple cellular automaton rule with growth inhibition captures the essential features of the usual partial differential equations, and reproduces the spatial patterns seen. Turbulent fluids may also potentially be modelled as cellular automata with local interactions between discrete vortices on lattice sites.

If probabilistic noise is added to the time evolution rule (1), then cellular automata may be identified as generalized Ising models[9,10]. Phase transitions may occur if ϕ retains some deterministic components, or in more than one dimension.

Cellular automata may serve as suitable models for a wide variety of biological systems. In particular, they may suggest mechanisms for biological pattern formation. For example, the patterns of pigmentation found on many mollusc shells bear a striking resemblance to patterns generated by class 2 and 3 cellular automata (see refs 11, 12), and cellular automaton models for the growth of some pigmentation patterns have been constructed[13].

Mathematical approaches

Rather than describing specific applications of cellular automata, this article concentrates on general mathematical features of their behaviour. Two complementary approaches provide characterizations of the four classes of behaviour seen in Fig. 3.

In the first approach[2], cellular automata are viewed as discrete dynamical systems (see ref. 14), or discrete idealizations of partial differential equations. The set of possible (infinite) configurations of a cellular automaton forms a Cantor set; cellular automaton evolution may be viewed as a continuous mapping on this Cantor set. Quantities such as entropies, dimensions and Lyapunov exponents may then be considered for cellular automata.

In the second approach[3], cellular automata are instead considered as information-processing systems (see ref. 15), or parallel-processing computers of simple construction. Information represented by the initial configuration is processed by the evolution of the cellular automaton. The results of this information processing may then be characterized in terms of the types of formal languages generated. (Note that the mechanisms for information processing in natural system appear to be much closer to those in cellular automata than in conventional serial-processing computers: cellular automata may, therefore, provide efficient media for practical simulations of many natural systems.)

Entropies and dimensions

Most cellular automaton rules have the important feature of irreversibility: several different configurations may evolve to a single configuration, and, with time, a contracting subset of all possible configurations appears. Starting from all possible initial configurations, the cellular automaton evolution may generate only special 'organized' configurations, and 'self-organization' may occur.

For class 1 cellular automata, essentially all initial configurations evolve to a single final configuration, analogous to a limit point in a continuous dynamical system. Class 2 cellular automata evolve to limit sets containing essentially only periodic configurations, analogous to limit cycles. Class 3 cellular automata yield chaotic aperiodic limit sets, containing analogues of chaotic or 'strange' attractors.

Entropies and dimensions give a generalized measure of the density of the configurations generated by cellular automaton evolution. The (set) dimension or limiting (topological) entropy for a set of cellular automaton configurations is defined as (compare ref. 14)

$$d^{(x)} = \lim_{X\to\infty} \frac{1}{X} \log_k N(X) \tag{2}$$

where $N(X)$ gives the number of distinct sequences of X site values that appear. For the set of possible initial configurations, $d^{(x)} = 1$. For a limit set containing only a finite total number of configurations, $d^{(x)} = 0$. For most class 3 cellular automata, $d^{(x)}$ decreases with time, giving, $0 < d^{(x)} < 1$, and suggesting that a fractal subset of all possible configurations occurs.

A dimension or limiting entropy $d^{(t)}$ corresponding to the time series of values of a single site may be defined in analogy with equation (2). (The analogue of equation (2) for a sufficiently wide patch of sites yields a topologically-invariant entropy for the cellular automaton mapping.) $d^{(t)} = 0$ for periodic sets of configurations.

$d^{(x)}$ and $d^{(t)}$ may be modified to account for the probabilities of configurations by defining

$$d_\mu^{(x)} = -\lim_{X\to\infty} \frac{1}{X} \sum_{j=1}^{k^X} p_j \log_k p_j \tag{3}$$

and its analogue, where p_j are probabilities for possible length X sequences. These measure dimensions may be used to delineate the large time behaviour of the different classes of cellular automata:

(1) $d_\mu^{(x)} = d_\mu^{(t)} = 0$
(2) $d_\mu^{(x)} > 0,\ d_\mu^{(t)} = 0$
(3) $d_\mu^{(r)} > 0,\ d_\mu^{(t)} > 0$

As discussed below, dimensions are usually undefined for class 4 cellular automata.

Information propagation

Cellular automata may also be characterized by the stability or predictability of their behaviour under small perturbations in initial configurations. Figure 2 shows differences in patterns generated by cellular automata resulting from a change in a

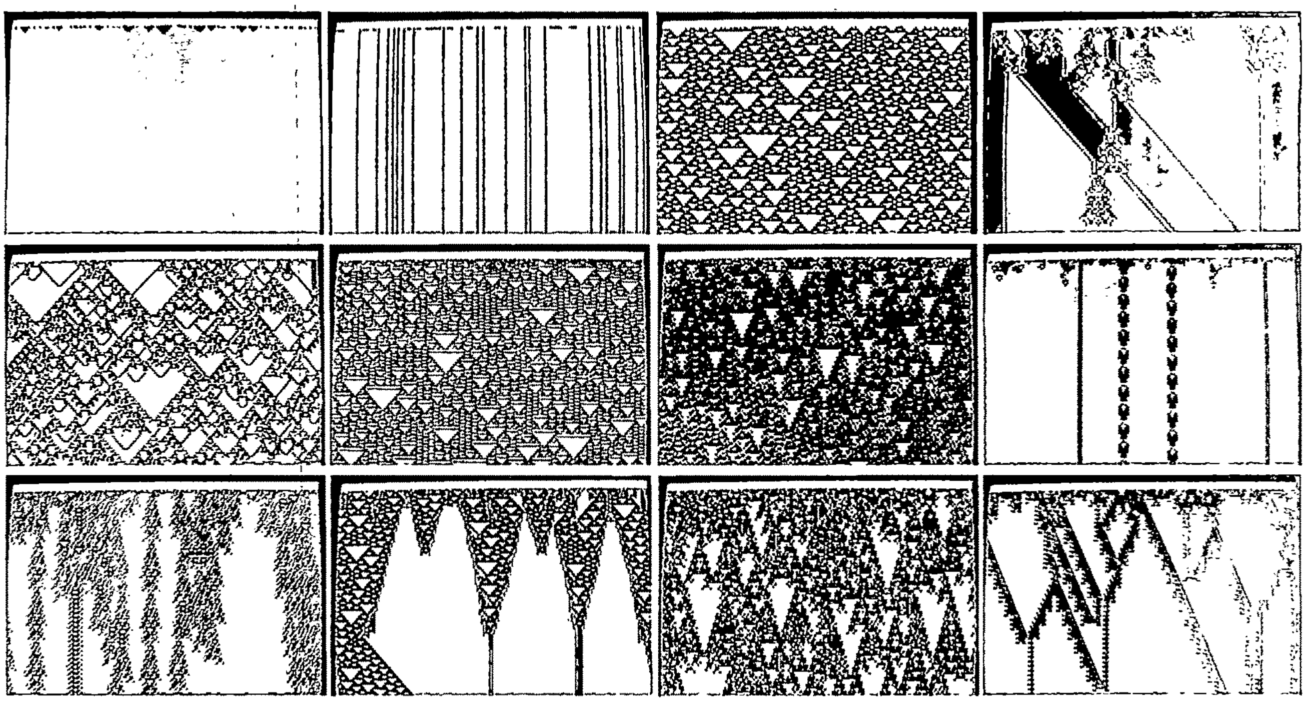

Fig. 3 Evolution of various cellular automata from disordered initial states. In many cases, ordered structure is seen to be generated. The first row of pictures show examples of the four qualitative classes of behaviour found. (The rules shown are the same as in Fig. 1.) The lower two rows show examples of cellular automata with $k=5$ (five possible values for each site) and $r=1$ (nearest neighbour rules). Site values 0 to 4 are represented by white, red, green, blue and yellow squares, respectively. (The rules shown have totalistic codes 10175, 566780, 570090, 580020, 583330, 672900, 5694390, 59123000.) The 'orange' discoloration is a background, not part of the pattern.

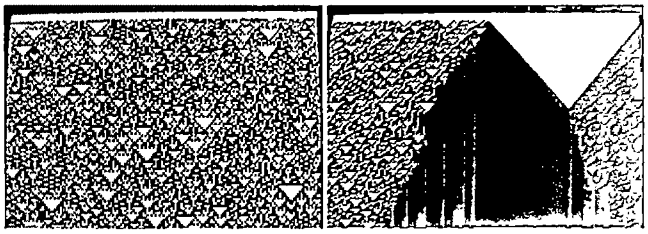

Fig. 4 Evolution of multiple phases in cellular automata. Pairs of sites are shown combined: 00 is represented by white, 01 by red, 10 by green and 11 by blue. Alternate time steps are shown. Both rules simulate an additive rule (number 90) under a blocking transformation. In the first rule (number 18), the simulation is attractive: starting from a disordered initial state, the domains grow with time. In the second rule (number 94), the simulation is repulsive: only evolution from a special initial state yields additive rule behaviour; a defect is seen to grow, and attractive simulation of the identity rule takes over.

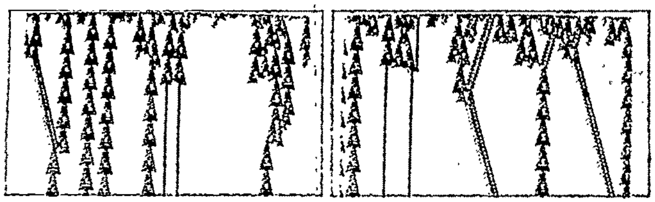

Fig. 5 Examples of the evolution of a typical class 4 cellular automaton from disordered initial states. This and other class 4 cellular automata are conjectured to be capable of arbitrary information processing, or universal computation. The rule shown has $k=3$, $r=1$, and takes the value of a site to be 1 if the sum of the values of the sites in its three-site neighbourhood is 2 or 6, to be 2 if the sum is 3, and to zero otherwise (totalistic code 792).

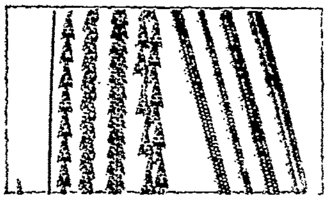

Fig. 6 Persistent structures generated in the evolution of the class 4 cellular automaton of Fig. 5. The first four structures shown have periods 1, 20, 16 and 12 respectively; the last four structures (and their reflections) propagate: the first has period 32, the next three period 3, and the last period 6. These structures are some of the elements required to support universal computation.

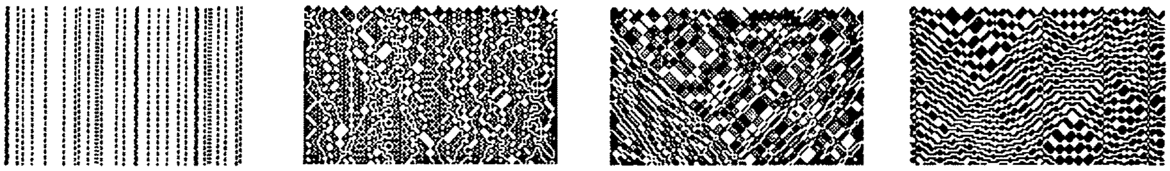

Fig. 7 Evolution of some cellular automata with reverisble rules. Each configuration is a unique function of the two previous configurations. (Rule numbers 4, 22, 90 and 126 are shown.) As initial conditions, each site in two successive configurations is chosen to have value 1 with probability 0.1.

single initial site value. Such perturbations have characteristic effects on the four classes of cellular automata:

(1) no change in final state;
(2) changes only in a finite region;
(3) changes over an ever-increasing region;
(4) irregular changes.

In class 1 and 2 cellular automata, information associated with site values in the initial state propagates only a finite distance; in class 3 cellular automata, it propagates an infinite distance at a fixed speed, while in class 4 cellular automata, it propagates irregularly, but over an infinite range. The speed of information propagation is related to the Lyapunov exponent for the cellular automaton evolution, and measures the degree of sensitivity to initial conditions (see ref. 16). It leads to different degrees of predictability for the outcome of cellular automaton evolution:

(1) entirely predictable, independent of initial state;
(2) local behaviour predictable from local initial state;
(3) behaviour depends on an ever-increasing initial region;
(4) behaviour effectively unpredictable.

Information propagation is particularly simple for the special class of additive cellular automata (whose local rule function ϕ is linear modulo k), in which patterns generated from arbitrary initial states may be obtained by superposition of patterns generated by evolution of simple initial states containing a single non-zero site. A rather complete algebraic analysis of such cellular automata may be given[17]. Most cellular automata are not additive; however, with special initial configurations it is often possible for them to behave just like additive rules. Thus, for example, the evolution of an initial configuration consisting of a sequence of 00 and 01 digrams under one rule may be identical to the evolution of the corresponding 'blocked' configuration consisting of 0 and 1 under another rule. In this way, one rule may simulate another under a blocking transformation (analogous to a renormalization group transformation). Evolution from an arbitrary initial state may be attracted to (or repelled from) the special set of configurations for which such a simulation occurs. Often several phases exist, corresponding to different blocking transformations: sometimes phase boundaries move at constant speed, and one phase rapidly takes over; in other cases, phase boundaries execute random walks, annihilating in pairs, and leading to a slow increase in the average domain size, as illustrated in Fig. 4. Many rules appear to follow attractive simulation paths to additive rules, which correspond to fixed points of blocking transformations, and thus exhibit self similarity. The behaviour of many rules at large times, and on large spatial scales, is therefore determined by the behaviour of additive rules.

Thermodynamics

Decreases with time in the spatial entropies and dimensions of equations (2) and (3) signal irreversibility in cellular automaton evolution. Some cellular automaton rules are, however, reversible, so that each and every configuration has a unique predecessor in the evolution, and the spatial entropy and dimension of equations (2) and (3) remain constant with time. Figure 7 shows some examples of the evolution of such rules, constructed by adding a term $-a_i^{(t-1)}$ to equation (1) (ref. 20 and E. Fredkin, personal communication). Again, there are analogues of the four classes of behaviour seen in Fig. 3, distinguished by the range and speed of information propagation.

Conventional thermodynamics gives a general description of systems whose microscopic evolution is reversible; it may, therefore, be applied to reversible cellular automata such as those of Fig. 4. As usual, the 'fine-grained' entropy for sets (ensembles) of configurations, computed as in equation (3) with perfect knowledge of each site value, remains constant in time. The 'coarse-grained' entropy for configurations is, nevertheless, almost always non-decreasing with time, as required by the second law of thermodynamics. Coarse graining emulates the imprecision of practical measurements, and may be implemented by applying almost any contractive mapping to the configurations (a few iterations of an irreversible cellular automaton rule suffice). For example, coarse-grained entropy might be computed by applying equation (3) to every fifth site value. In an ensemble with low coarse-grained entropy, the values of every fifth site would be highly constrained, but arbitrary values for the intervening sites would be allowed. Then in the evolution of a class 3 or 4 cellular automaton the disorder of the intervening site values would 'mix' with the fifth-site values, and the coarse-grained entropy would tend towards its maximum value. Signs of self-organization in such systems must be sought in temporal correlations, often manifest in 'fluctuations' or metastable 'pockets' of order.

While all fundamental physical laws appear to be reversible, macroscopic systems often behave irreversibly, and are appropriately described by irreversible laws. Thus, for example, although the microscopic molecular dynamics of fluids is reversible, the relevant macroscopic velocity field obeys the irreversible Navier–Stokes equations. Conventional thermodynamics does not apply to such intrinsically irreversible systems: new general principles must be found. Thus, for cellular automata with irreversible evolution rules, coarse-grained entropy typically increases for a short time, but then decreases to follow the fine-grained entropy. Measures of the structure generated by self-organization in the large time limit are usually affected very little by coarse graining.

Formal language theory

Quantities such as entropy and dimension, suggested by information theory, give only rough characterizations of cellular automaton behaviour. Computation theory suggests more complete descriptions of self-organization in cellular automata (and other systems). Sets of cellular automaton configurations may be viewed as formal languages, consisting of sequences of symbols (site values) forming words according to definite grammatical rules.

The set of all possible initial configurations corresponds to a trivial formal language. The set of configurations obtained after any finite number of time steps are found to form a regular language[3]. The words in a regular language correspond to the possible paths through a finite graph representing a finite state machine. It can be shown that a unique smallest finite graph reproduces any given regular language (see ref. 15). Examples of such graphs are shown in Fig. 8. These graphs give complete specifications for sets of cellular automaton configurations (ignoring probabilities). The number of nodes Ξ in the smallest graph corresponding to a particular set of configurations may

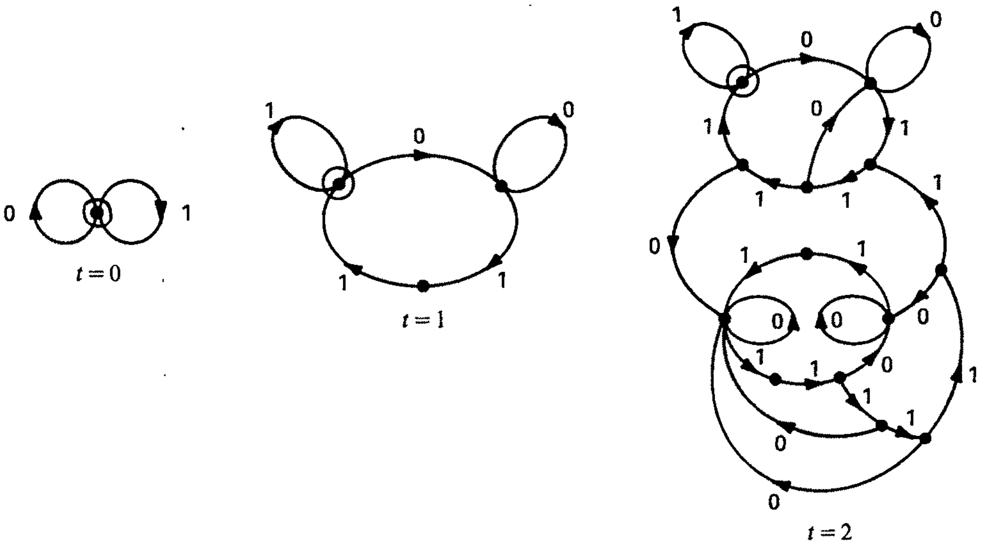

Fig. 8 Graphs representing the sets of configurations generated in the first few time steps of evolution according to a typical class 3 cellular automaton rule ($k=2$, $r=1$, rule number 126). Possible configurations correspond to possible paths through the graphs, beginning at the encircled node. At $t=0$, all possible configurations are allowed. With time, a contracting subset of configurations are generated. (After one time step, for example, no configuration containing the sequence of site value 101 can appear.) At each time step, the complete set of possible configurations forms a regular formal language: the graph gives a minimal complete specification of it. The number of nodes in the graph gives a measure of the complexity Ξ of the set, viewed as a regular language. As for other class 3 cellular automata, the complexity of the sets grows rapidly with time; for $t=3$, $\Xi=107$, and $t=4$, $\Xi=2{,}867$.

be defined as the 'regular language complexity' of the set. It specifies the size of the minimal description of the set in terms of regular languages. Larger Ξ correspond to more complicated sets. (Note that the topological entropy of a set is given by the logarithm of the algebraic integer obtained as the largest root of the characteristic polynomial for the incidence matrix of the corresponding graph. The characteristic polynomials for the graphs in Fig. 7 are $2-\lambda$ ($\lambda_{\max}=2$), $1-\lambda+2\lambda^2-\lambda^3$ ($\lambda_{\max}\simeq 1.755$) and $-1+\lambda-\lambda^2+2\lambda^3-4\lambda^4+\lambda^5+3\lambda^6-5\lambda^7+3\lambda^8-3\lambda^9+5\lambda^{10}-6\lambda^{11}+4\lambda^{12}-\lambda^{13}$ ($\lambda_{\max}\simeq 1.732$), respectively.)

The regular language complexity Ξ for sets generated by cellular automaton evolution almost always seems to be non-decreasing with time. Increasing Ξ signals increasing self-organization. Ξ may thus represent a fundamental property of self-organizing systems, complementary to entropy. It may, in principle, be extracted from experimental data.

Cellular automata that exhibit only class 1 and 2 behaviour always appear to yields sets that correspond to regular languages in the large time limit. Class 3 and 4 behaviour typically gives rise, however, to a rapid increase of Ξ with time, presumably leading to limiting sets not described by regular languages.

Formal languages are recognized or generated by idealized computers with a 'central processing unit' containing a fixed finite number of internal states, together with a 'memory'. Four types of formal languages are conventionally identified, corresponding to four types of computer:

- Regular languages: no memory required.
- Context-free languages: memory arranged as a last-in, first-out stack.
- Context-sensitive languages: memory as large as input word required.
- Unrestricted languages: arbitrarily large memory required (general Turing machine).

Examples are known of cellular automata whose limiting sets correspond to all four types of language (L. Hurd, in preparation). Arguments can be given that the limit sets for class 3 cellular automata typically form context-sensitive languages, while those for class 4 cellular automata correspond to unrestricted languages. (Note that while a minimal specification for any regular language may always be found, there is no finite procedure to obtain a minimal form for more complicated formal languages: no generalization of the regular language complexity Ξ may thus be given.)

Computation theory

While dynamical systems theory concepts suffice to define class 1, 2 and 3 cellular automata, computation theory is apparently required for class 4 cellular automata. Examples of the evolution of a typical class 4 cellular automaton are shown in Fig. 5. Varied and complicated behaviour, involving many different time scales is evident. Persistent structures are often generated; the smallest few are illustrated in Fig. 6, and are seen to allow both storage and transmission of information. It seems that the structures supported by this and other class 4 cellular automata rule may be combined to implement arbitrary information processing operations. Class 4 cellular automata would then be capable of universal computation: with particular initial states, their evolution could implement any finite algorithm. (Universal computation has been proved for a $k=18$, $r=1$ rule[22], and for two-dimensional cellular automata such as the 'Game of Life'[22,23].) A few per cent of cellular automaton rules with $k>2$ or $r>1$ are found to exhibit class 4 behaviour: all these would then, in fact, be capable of arbitrarily complicated behaviour. This capability precludes a smooth infinite size limit for entropy or other quantities: as the size of cellular automaton considered increases, more and more complicated phenomena may appear.

Cellular automaton evolution may be viewed as a computation. Effective preidiction of the outcome of cellular automaton evolution requires a short-cut that allows a more efficient computation than the evolution itself. For class 1 and 2 cellular automata, such short cuts are clearly possible: simple computations suffice to predict their complete future. The computational capabilities of class 3 and 4 cellular automata may, however, be sufficiently great that, in general, they allow no short-cuts. The only effective way to determine their evolution from a given initial state would then be by explicit observation or simulation: no finite formulae for their general behaviour could be given. (If class 4 cellular automata are indeed capable of universal computation, then the variety of their possible behaviour would preclude general prediction, and make explicit observation or simulation necessary.) Their infinite time limiting behaviour could then not, in general, be determined by any finite computational process, and many of their limiting properties would be formally undecidable. Thus, for example, the 'halting problem' of determining whether a class 4 cellular automaton with a given finite initial configuration ever evolves to the null configuration would be undecidable. An explicit simulation could determine only whether halting occurred before some fixed time, and not whether it occurred after an arbitrarily long time.

For class 4 cellular automata, the outcome of evolution from almost all initial configurations can probably be determined only by explicit simulation, while for class 3 cellular automata this is the case for only a small fraction of initial states. Nevertheless, this possibility suggests that the occurrence of particular site value sequences in the infinite time limit is in general undecidable. The large time limit of the entropy for class 3 and 4 cellular automata would then, in general, be non-computable: bounds on it could be given, but there could be no finite procedure to compute it to arbitrary precision. (This would be the case if the limit sets for class 3 and 4 cellular automata formed at least context-sensitive languages.)

While the occurrence of a particular length n site value sequence in the infinite time limit may be undecidable, its occurrence after any finite time t can, in principle, be determined by considering all length $n_0 = n + 2rt$ initial sequences that could evolve to it. For increasing n or t this procedure would, nevertheless, involve exponentially-growing computational resources, so that it would rapidly become computationally intractable. It seems likely that the identification of possible sequences generated by class 3 and 4 cellular automata is, in general, an NP-complete problem (see ref. 15). It can, therefore, presumably not be solved in any time polynomial in n or t, and essentially requires explicit simulation of all possibilities.

Undecidability and intractability are common in problems of mathematics and computation. They may well afflict all but the simplest cellular automata. One may speculate that they are widespread in natural systems, perhaps occurring almost whenever nonlinearity is present. No simple formulae for the behaviour of many natural systems could then be given; the consequences of their evolution could be found effectively only by direct simulation or observation.

ARTICLES

Orientation of *in situ* stresses in the oceanic crust

Robin L. Newmark*†, Mark D. Zoback‡ & Roger N. Anderson*

* Borehole Research Group, Lamont-Doherty Geological Observatory, and † Department of Geological Sciences, Columbia University, Palisades, New York 10964, USA
‡ Branch of Tectonophysics, US Geological Survey, Menlo Park, California 94025, USA

Two in situ *measurements of principal stress directions have been made in DSDP Holes 504B, south of the Costa Rica Rift on the Nazca plate, and 597C, west of the East Pacific Rise on the Pacific plate. In both cases, the orientations of* in situ *principal stresses determined from borehole breakouts are consistent with the stress directions inferred from intraplate earthquakes located near the sites.*

WELLBORE breakouts are intervals of borehole elongation which are caused by preferential spalling in a zone where the circumferential compressive stress is greatest[1], and in which the average azimuth of the long dimension is consistent in a given well or field[2,3]. Stress-induced wellbore breakouts form at an azimuth perpendicular to the maximum horizontal principal stress direction[1]. Wellbore breakouts have been reported in wells from several parts of North America[2–15] but there have been problems in their identification (see ref. 16). There now seems to be ample evidence that breakouts can be used as a reliable indicator of the orientation of the horizontal principal stresses. Here, we use specially processed borehole televiewer data to study the detailed shape of breakouts (see ref. 1).

Borehole televiewer reflectivity records have previously been used in the study of fractures intersecting wellbores at depth (see ref. 17), for identifying lithostratigraphical features in deep ocean boreholes (see refs 18, 19), and in identifying zones of borehole breakout[1,20,21].

Experimental data

Evidence of the orientation of the contemporary *in situ* stress field can be found at two DSDP (Deep Sea Drilling Project) sites in the oceanic crust (Fig. 1). DSDP Site 504 is located 200 km due south of the Costa Rica Rift and about 350 km north-west of the Peru-Chile Trench. DSDP Site 597 is located about 1,800 km west of the East Pacific Rise and 2,000 km east of Tahiti.

During DSDP Leg 83, the DV *Glomar Challenger* completed drilling Hole 504B to a depth of 1,350 m, 1,000 m of which was into basement[22] (Fig. 1). The upper 100 m of basement[19] is composed mainly of pillow basalts and thin flow units of seismic layer 2A. The next 550 m of pillows, breccias and flows is a site of intense fracturing, and contains extensive secondary alteration; it is thought to be seismic layer 2B. The bottom 350 m of the hole is composed mainly of massive, 'welded' units, or sheeted dykes, and is the upper part of seismic layer 2C.

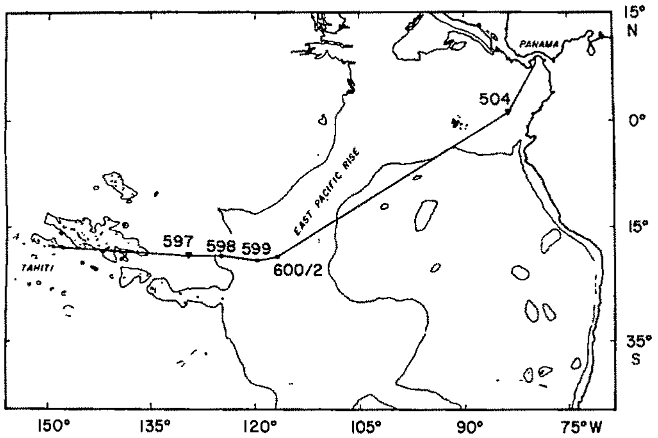

Fig. 1 Location of DSDP Sites 504 and 597 along ship track for DSDP Leg 92.

Borehole televiewer (BHTV) images run in Hole 504B suggested the presence of breakouts at many intervals down the hole. Our breakout analysis of the BHTV records was confined to the lower 350 m of the hole, because the borehole walls in the lower part of the hole are relatively smooth (apart from the breakout intervals), in comparison to the washed out, pitted and broken nature of the wellbore in the upper zones of pillows and breccias. For analysis of the BHTV records, cross-sectional travel-time images were produced every few centimetres in breakout zones in the lower 350 m of the hole. These form 360° caliper images of the wellbore. The criteria which were used to confirm the breakouts included: (1) the wellbore should have two bands of spalling, separated by 180°±20°; and (2) evidence of the same cross-sectional outline and orientation should persist over several (>4) consecutive rotations of the tool's acoustic transducer, indicating breakout continuity of several centimetres for each measurement.

Figure 2*b* shows a reflectivity record of a 5 m-long interval from Hole 504B which is oriented with respect to magnetic north. Hard, smooth surfaces produce white zones (high-amplitude reflectance), and fractures, voids and soft material, which would absorb much of the signal, produce dark zones (low-amplitude reflectance). The vertical, dark bands seen at azimuths of about 120° and 300° are breakout zones. Figure 2*c* shows a cross-sectional, 360° caliper view of the breakout at a depth of 944 m into basement which was made by plotting the travel time of the reflected acoustic pulse as a function of azimuth.

In all, 65 measurements of orientations of breakouts which conformed to the above listed criteria were made in the records obtained in the lower 350 m of Hole 504B. Figure 3*b* shows examples of breakout cross-sections at other depths through this depth interval. The azimuths (with respect to magnetic north) of the midpoints of each breakout zone are plotted against depth in Fig. 3*a*. The mean azimuths are N112E ± 16° (±s.d.) and N296E ± 16°, with a mean separation of 184° ± 11°. This indicates an average maximum horizontal compressional stress oriented at N24E magnetic, which, when corrected for magnetic declination (4.5° east), results in a maximum horizontal stress direction of N20E ± 16° at the site.

During DSDP Leg 92, as part of a hydrogeology investigation (Fig. 1), a series of holes was drilled at sites which form a west–east transect across the western flank of the East Pacific Rise, at 19° South. Hole 597C, a re-entry hole, was drilled 91 m into the 28.5-Myr-old crust, generated at the now-extinct but fast-spreading Galapagos Rise. Massive flows appear to comprise the entire sequence. This is supported by both the BHTV amplitude records and the core recovery which ranged up to 94%. Only one small fragment which might possibly be a pillow margin was recovered[23]. The caliper logs indicate that the borehole has few abrupt changes in diameter, and the BHTV amplitude records show the wellbore as having a generally uniform and solid appearance, with few zones of low reflectivity.

In some intervals, zones of borehole breakout oriented NNE–SSW were identified. Because of the otherwise smooth and solid character of the wellbore, the presence of breakouts is readily recognized in travel-time processing of the BHTV records (Fig. 3*d*). In all, 18 measurements of breakout orientations were made in the BHTV records from the upper 50 m of basement in Hole 597C (Fig. 3*c*, *d*). Unlike the measurements from Hole 504B, each of these measurements was made using data from only two rotations of the tool because cold formation temperatures slowed the speed of tool rotation. The azimuths (with respect to magnetic north) of the midpoints of each breakout zone are plotted against depth in Fig. 3*c*. The mean azimuths are N30E

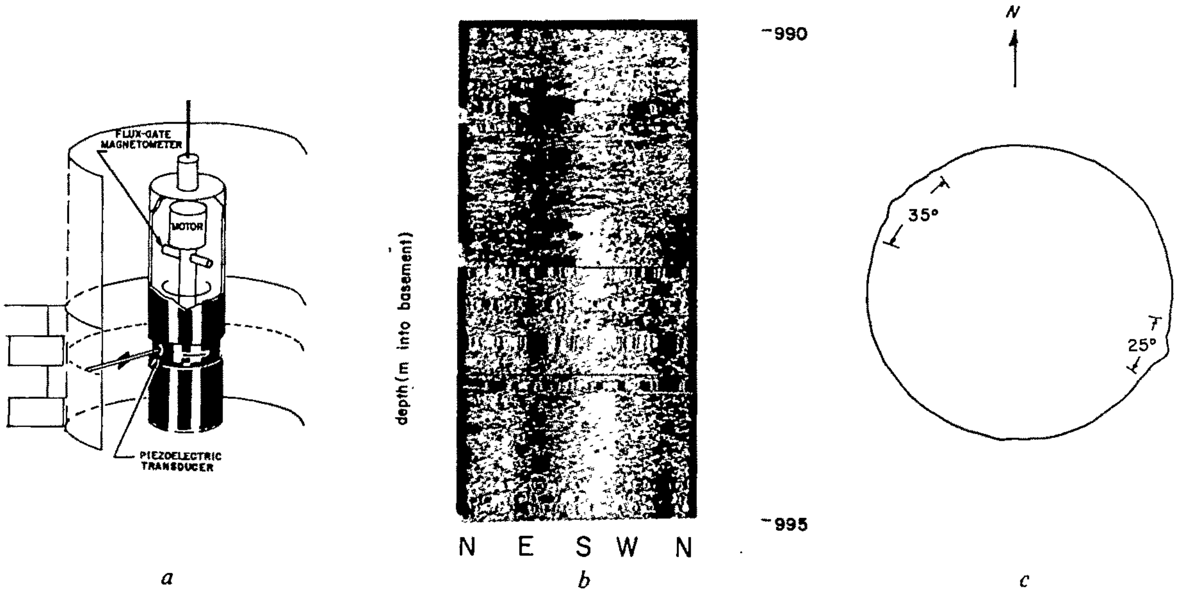

Fig. 2 *a*, Schematic of the borehole televiewer. The televiewer contains a rotating piezoelectric transducer which emits and receives an ultrasonic pulse 600 times a revolution as it rotates three times per s[33]. The amplitude of the reflected acoustic pulse can be plotted on a three-axis oscilloscope as a function of beam azimuth and vertical position in the hole, producing an image of wellbore reflectivity, or smoothness. The travel time of the reflected acoustic pulse can be plotted as a function of beam azimuth, which results in a detailed cross-sectional image of the wellbore. A fluxgate magnetometer triggers the scope trace at magnetic north so that the orientation of observed features can be determined. *b*, Amplitude, or plan-view borehole televiewer record of 5 m of Hole 504B. Width across image is about 1 m. Dark vertical bands oriented ESE–WNW are breakout zones. *c*, Cross-section of Hole 504B at a depth of 944 m into basement, showing breakout.

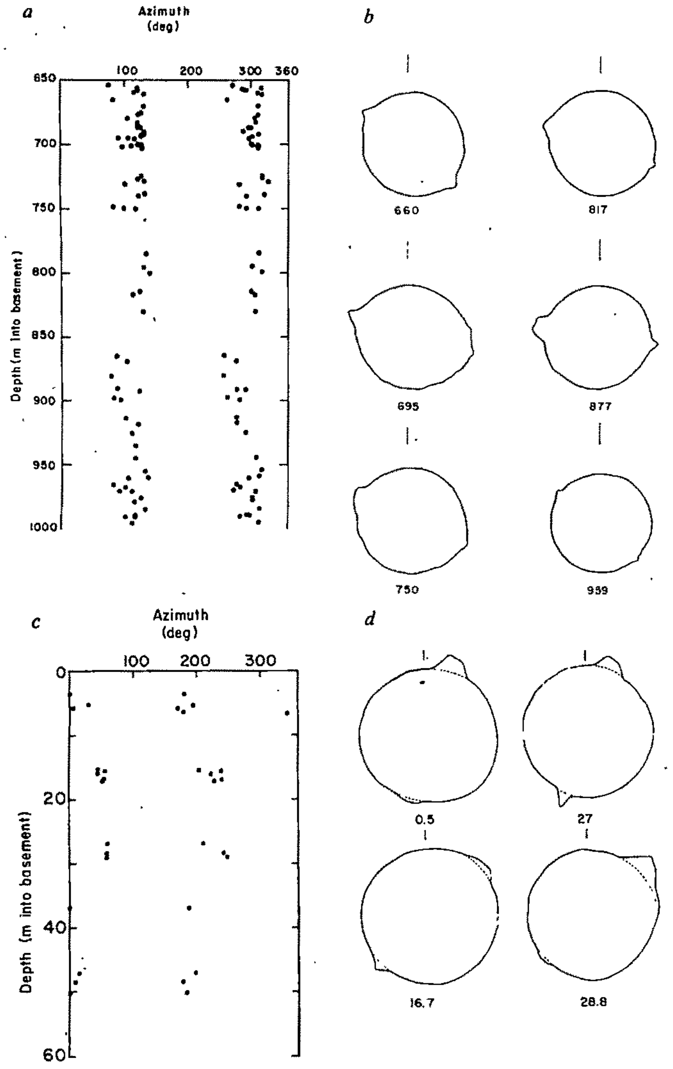

Fig. 3 Azimuths (with respect to magnetic north) of the mid-points of borehole breakouts plotted against depth in *a*, Hole 504B; *c*, Hole 597C. Mean azimuths are N112E and N296E ± 16° (*a*) and N30E and N208E ± 25° (*c*). Examples of breakout cross-sections in *b*, Hole 504B; *d*, Hole 597C. Vertical lines indicate true north. Numbers indicate depth in metres into basement.

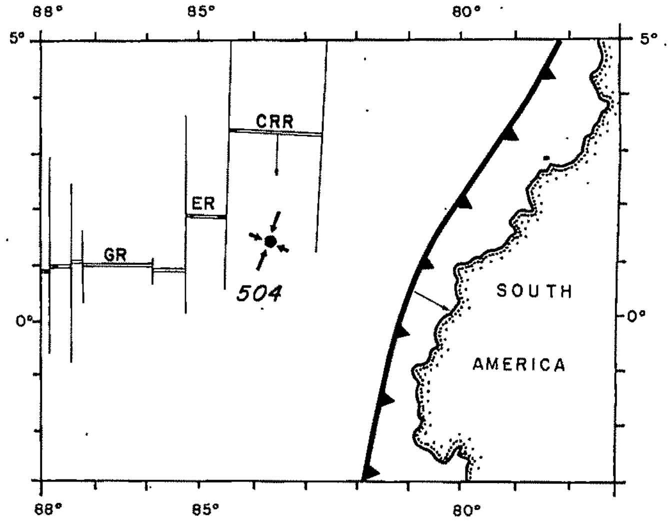

Fig. 4 Stresses near Site 504. Heavy arrows indicate the principal horizontal compressive stress directions determined from breakout directions at Hole 504B. Light arrows show the direction of ridge-push force from the Costa Rica Rift and the direction of the slab-pull force from the Peru–Chile Trench. Double lines indicate the ridge axis of the Cocos–Nazca spreading system and hatched line is the Peru–Chile Trench[32]. CRR, Costa Rica Rift; ER, Ecuador Rift; GR, Galapagos Rift.

and N208E ± 25°, with a mean separation of 178°. This indicates an average maximum horizontal compressional stress direction of N121E magnetic, which, when corrected for magnetic declination results in a maximum horizontal stress oriented N110E ± 25° at the site.

Discussion

DSDP Hole 504B is located 200 km due south of the east–west-trending Costa Rica Rift and about 350 km NW of the NE–SW-trending Peru–Chile Trench. Ridge push from the Costa Rica Rift should produce a southward compression at the site. The net slab pull, or the sum of driving and resisting slab forces, should produce southeastward extensional stresses at the site (Fig. 4).

As shown in Fig. 4, the observed maximum principal horizontal stress direction is oriented almost parallel to the north–south compression expected from a ridge-push force from the Costa Rica Rift. This would seem to suggest the dominance of the ridge-push force at this site. However, the slab pull force associated with subduction of the Nazca plate along the Peru–Chile Trench is expected to generate east-southeast-oriented extensional stresses. Because the observed direction of least principal stress is N110E, it is nearly parallel to the predicted direction of trench pull. Thus, it is not clear from the orientation of the principal horizontal stresses at Hole 504B whether ridge push, or trench pull, is the dominant mechanism controlling the *in situ* stress field. In any event, this direction is consistent with focal mechanism solutions of earthquakes located near the site, which exhibit a dominant NNE–SSW P-axis orientation[24].

DSDP Hole 597C is located ~1,800 km west of the East Pacific Rise (Fig. 1). Ridge push from the East Pacific Rise should produce west-northwest-oriented compression at the site. As can be seen in Fig. 5, the maximum horizontal compression at Site 597C is parallel to both the relative and absolute plate motion vectors for the Pacific plate, both of which are consistent with an interpretation of a dominant ridge-push force acting at the site.

The shaded areas in Fig. 5 indicate the local range of uncertainty in identifying the Okal and Bergeal 'J' line[25] which separates lithosphere generated at the Galapagos Rise before the Miocene ridge jump from lithosphere generated at the East Pacific Rise. It is a line of age discontinuity and may represent a zone of weakness in the plate. Because the ridge jump was accompanied by a change in the azimuth of spreading, the J line separates lithosphere with differing tectonic orientations. Fracture zones trend N250E in the older lithosphere and N290E in the younger lithosphere.

The anomalous intraplate seismicity in this area graphically demonstrates a change in the consistency of stress orientations inferred from intraplate earthquakes located in crust on either side of the J line. Focal mechanism solutions of several intraplate earthquakes located in the general vicinity of Site 597 are shown in Fig. 5 (refs 24, 26–29).

LI2, GB4 and GB5 correspond to Okal *et al.*'s[26] regions A, B and C, respectively. Each of these clusters has horizontal dimensions of ≤50 km. All solutions indicate focal depths of ≤5 km. A seismic network in French Polynesia has provided a detailed account of the seismicity in these regions over the past several years[26].

At LI2, activity is characterized by swarms, mostly with strike-slip solutions with some normal component. The P axes are oriented WNW–ESE which is nearly parallel to both the current relative and absolute plate motion vectors. There is no evidence of related local bathymetric features.

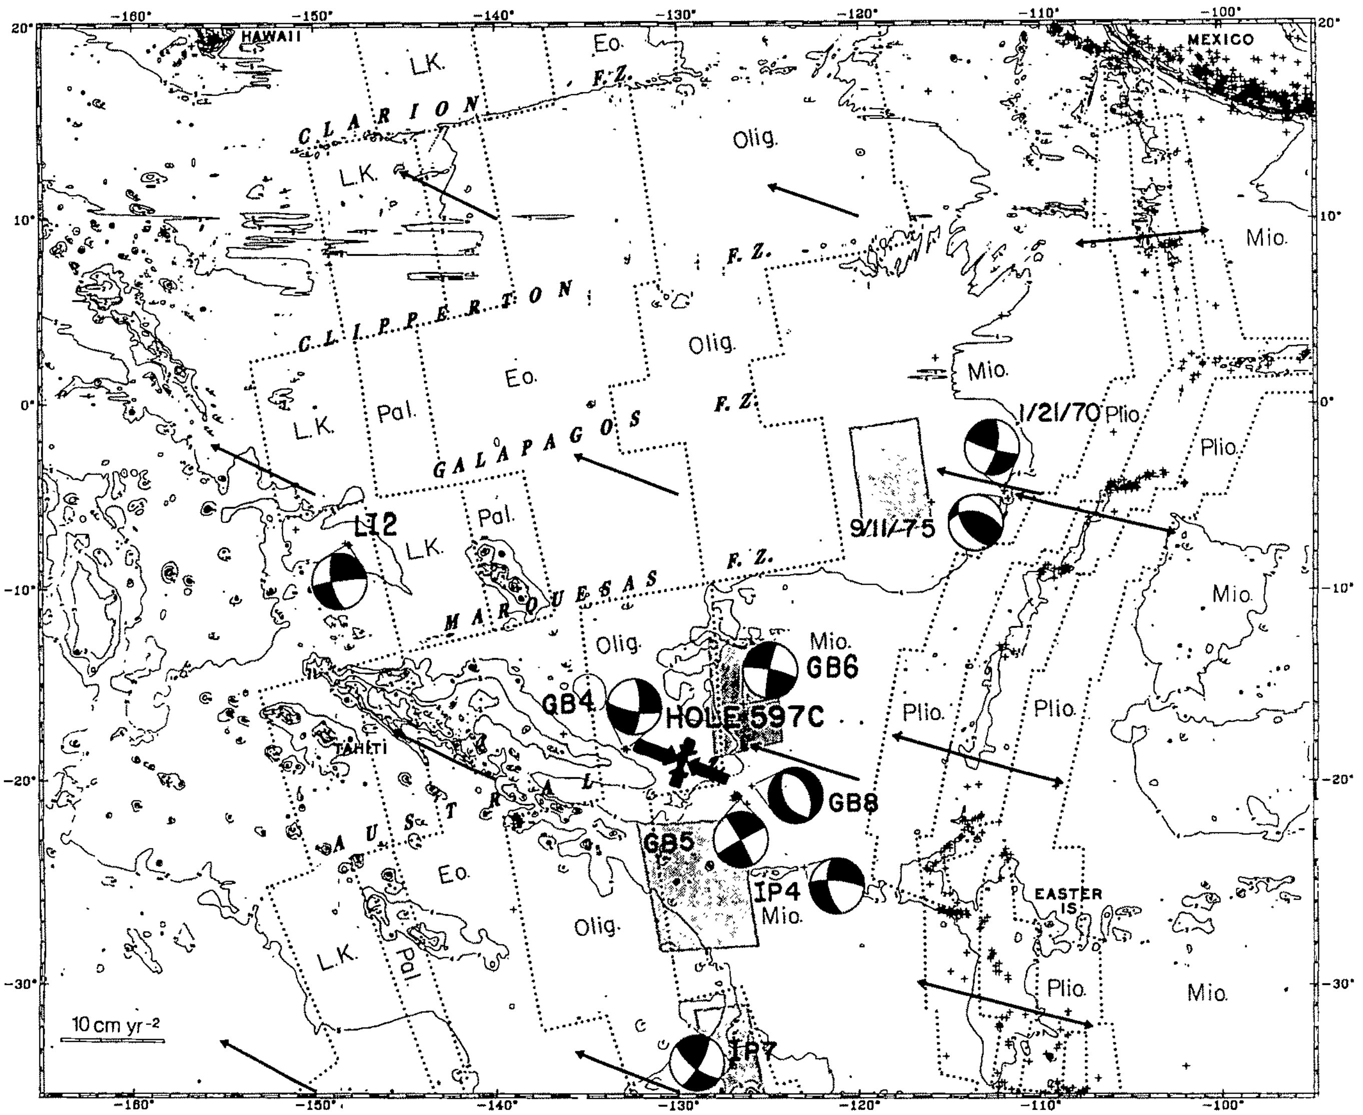

Fig. 5 Stresses near Site 597C. Heavy arrows indicate the principal horizontal stress directions determined from breakout directions at Hole 597C. Light single-headed arrows indicate the absolute Pacific plate motion, and light double-headed arrows show relative Pacific–Nazca plate motion[34]. The trend of the East Pacific Rise is shown by crosses which mark the locations of earthquakes with $m_b > 4.5$ mag and recorded by more than 10 stations by the International Seismological Centre between 1963 and 1979 [35]. Focal mechanism solutions are discussed in the text.

At GB4, activity occurred as discrete events through time, again mostly characterized by strike-slip solutions with some normal component. There were 12 events with body-wave magnitudes of up to 5.5 during 15 yr.

At GB5, there was a 3-yr swarm of intense activity from 1976 to 1979, with over 96 events—mostly characterized by strike-slip solutions, but unlike at LI2 or GB4, with some thrust component. This swarm was followed by a 3-yr period of quiescence when there was no activity with magnitude >4. In July 1983, a mainshock–aftershock pair of events occurred only 65 km away at GB8, with a purely normal solution, at depths of 15–20 km. There is no evidence of related local bathymetric features in the area.

IP4 is the site of one of the largest normal faulting events known in young oceanic lithosphere, with a body-wave magnitude of 6.8. Its epicentre lies north-west of a major seamount to which this activity may be related. IP7 is located in the range of uncertainty of the J line.

The focal mechanism solutions of earthquakes located in older crust (LI2 and GB4) indicate P axes oriented WNW–ESE, which are consistent with the interpretation of a dominant ridge-push force acting on the plate. However, focal mechanism solutions of events located at sites near the J line or in younger crust show more diverse orientations of P axes. At GB5 and GB8, events occurred with normal, thrust and strike-slip mechanisms, within 3 yr and 65 km.

Our Site 597 is located in crust just older than the J line and indicates a dominant stress orientation which is consistent with the stress regime inferred by the intraplate events in older crust. This is particularly satisfying because our measurement was made only in the upper 50 m of the oceanic crust.

Conclusions

Most events far from plate boundaries indicate compressive stresses which are thought to result from the gravitational force due to lithospheric thickening with age, or ridge-push force. However, both compressional and extensional events occur in young lithosphere. Various authors[29–31] have proposed ages of from 10 to 35 Myr for the transition between the near-ridge tectonic regime which may be dominated by local forces and the stress regime in stable plate interiors characterized by horizontal compression. Site 597 seems to be located very close to this transition zone west of the East Pacific Rise.

To date, two *in situ* measurements of principal stress orientations have been made in DSDP holes: at Hole 504B, south of the Costa Rica Rift on the Nazca plate and at Hole 597C, west of the East Pacific Rise on the Pacific plate. In both cases, the orientation of *in situ* principal stresses determined from borehole breakouts have been consistent with the stress directions inferred from intraplate earthquakes near the sites. The important point of this work is the demonstration that stress orientations can be reliably determined from borehole breakouts in the oceanic crust. With the advent of a new phase of deep ocean drilling, we are confident that these measurements, routinely made in boreholes at locations oriented with respect to major plate boundaries, will allow us to define more clearly the state of stress in the upper oceanic crust and the relationships between the driving forces of plate tectonics.

We thank the officers, crews and scientific party of the DV *Glomar Challenger* Legs 83 and 92, without whose diligence and hard work the televiewer logs could not have been successfully completed. Larry Mastin, Gray Jensen and several other people at the USGS provided invaluable technical assistance. Terry Engelder and Daniel Fornari greatly improved the content of this paper. This work was supported by NSF grants OCE 78-27026 and OCE 81-10919, Office of Naval Research contracts T0-0098 and T0-0132, scope HH and Joint Oceanographic Institutions Inc. contract JOI-66-84. Lamont-Doherty Geological Observatory contribution number 3702.

Mantle upflow under North America and plate dynamics

D. I. Gough

Institute of Earth and Planetary Physics, and Department of Physics, University of Alberta, Edmonton, Alberta, Canada T6G 2J1

In the development of plate dynamics there are two fundamental questions. First, do the plates slide over a passive asthenosphere, or are they driven by a convecting upper mantle? Second, are all ocean ridges passive, pull-apart plate margins, or do some lie above upcurrents in the mantle and in that sense become active margins? The combination of stress orientations in the crust of North America with other geophysical and geological information favours an active mantle interpretation, both for the North American plate and for the mantle upflow which lay beneath the East Pacific Rise in Tertiary times and which now lies beneath the western United States.

THE fundamental hypothesis of plate tectonics, that the Earth has a strong outer shell, or lithosphere, made up of a small number of quasi-rigid plates, is now well established. Earthquakes occur mainly along, and are used to locate, plate boundaries. Linear marine magnetic anomalies and earthquake mechanisms have been used to construct a detailed picture of the motions of the plates. The next step is to develop a similarly satisfactory account of the forces driving the plates. In this development of plate dynamics, an important question is whether the plates slide over a passive weak layer, or asthenosphere, under gravitational forces acting only on the plates themselves, or are driven by convection in the mantle through the asthenosphere as a coupling layer. In the latter case, one would expect to find active ocean ridges driven by upcurrents in the mantle, probably with rapid spreading rates; and probably also passive ridges where slower spreading is driven only by gravity acting on the plates. In the past 30 Myr, the boundary between the North American plate and adjacent plates under the Pacific Ocean has undergone a complex evolution. This article brings together a wide range of geological, geophysical and geochemical information to show that there is now an upward flow of mantle material under the western United States. The implication is that active convection in the mantle is driving the Pacific plate and maintaining compressive stress, in a NE–SW direction, in the North American plate.

Two well-known reconstructions[1,2] of the Cenozoic tectonic evolution of the Pacific–North American plate boundary started with a continuous subduction along the western margin of the continent, the Farallon Plate between that subduction and the East Pacific Rise (EPR) with its associated transform faults, and the Pacific Plate west of the EPR. After the first contact of the EPR and its transform faults with the subduction, some 30 Myr BP, triple junctions migrated to the south-east and north-west and replaced the subduction with the San Andreas transform fault system. In this process, the oceanic Farallon Plate disappeared, except its remnants the Gorda, Juan de Fuca and Explorer plates north of 40° N and the Cocos plate south of 23° N, all of which are still being subducted under North America.

For the present purpose I adopt this widely accepted model of the sequence of plate interactions over the past 50 Myr. If (as Atwater[2] assumed) the EPR had been a passive, pull-apart

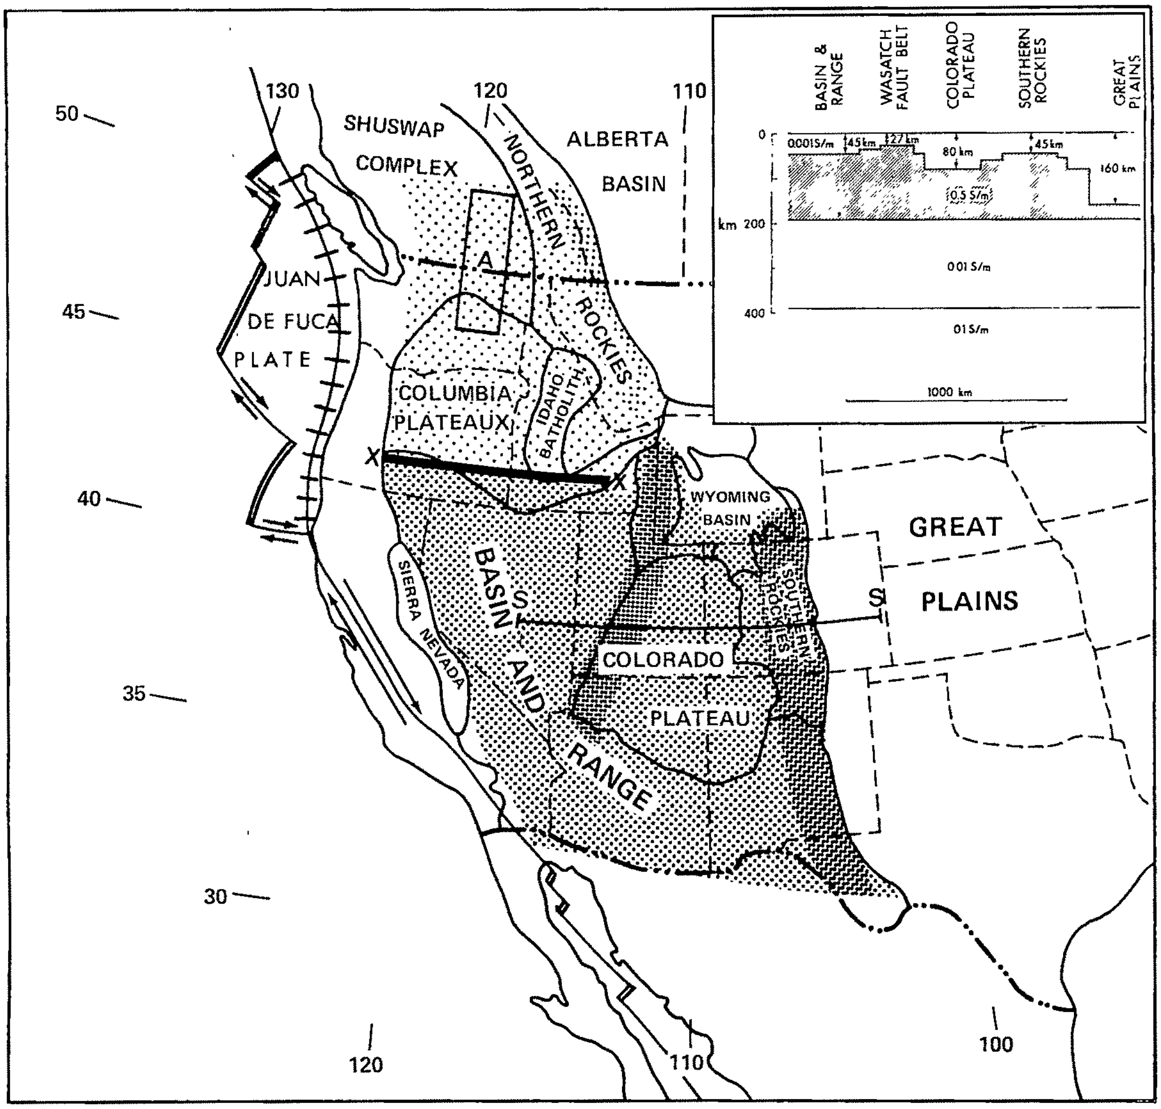

Fig. 1 The density of strippling on the map indicates variations of electrical conductance of an upper mantle layer. It is also believed to show partial melting. The section shows a model of conductive structure[26] along the east–west section SS. Major tectonic provinces are indicated.

margin, its replacement with the San Andreas Fault would not imply any marked thermal aftereffects within the continent. But if the EPR of Cenozoic times lay above a mantle upflow, such an upflow might now be present under the western US. Either possibility is consistent with earlier models[1,2] of the kinematics of the plates.

High temperatures and partial melting

There is abundant geophysical and geological evidence that temperatures in the upper mantle west of the undisturbed North American craton are higher than those beneath it. The boundary of the high-temperature régime lies at the eastern front of the Rocky Mountains[3,4]. West of this boundary the cratonic rocks of the Southern Rockies and Colorado Plateau (Fig. 1) have been uplifted in the Laramide orogeny[5], largely as a result of heating of the underlying upper mantle. The topographic uplift itself is highly significant as an indicator of the high-temperature region. Such features as the Colorado Plateau and the Grand Canyon show uplift of 3–4 km, and many mountains in the western US are peneplaned in this range of elevation. The igneous petrology of the region is even more significant. West and south of the Colorado Plateau the Basin and Range Province, and the Columbia Plateaus further north, are dominated by volcanic rocks of two types. Calc-alkaline andesitic volcanics were extruded in late Cretaceous and early Tertiary times, up to about 30 Myr BP (ref. 6). This epoch corresponds to the subduction regime in Atwater's[2] scheme, before the most easterly ridge segment reached the trench. The earlier, andesitic vulcanism can, therefore, be ascribed to ascent of melt from the downgoing plate on the model of Ringwood and Green[7], as shown in detail by Christiansen and Lipman[8]. Uplift of the Southern Rockies and Colorado Plateau probably occurred largely at that stage[5]. After 25 Myr BP basaltic vulcanism dominated the Basin and Range Province and Columbia Plateaus[8]. The basalts were extruded in great volume in an extensional stress field with most faults trending north–south. All of these observations receive a clear explanation if a mantle upflow, formerly feeding an active ridge at the EPR, lay under the Basin and Range Province after replacement of the ridge and trench with the San Andreas fault system. This is the explanation long held by J. Tuzo Wilson (ref. 9 and personal communications) and myself. Others[8,10] have preferred to regard the extensional fractures and basaltic extrusions as the result of oblique shearing transmitted from the San Andreas faults. This is probably the best account possible if one assumes that the EPR of early Tertiary times was a passive, pull-apart margin.

Regional variations of heat flow from the mantle confirm the thermal structure indicated by the volcanic rocks[3,4]. Seismology and electromagnetic geophysics reinforce the regional variations and add information in the depth dimension. For brevity the continent east of the Rocky Mountains is termed the 'craton', the region west of the craton the 'western region' within which lies the Basin and Range Province. Teleseismic P and S waves arriving vertically are delayed in the western region compared with the craton[11–13] in such a way as to show that the rigidity modulus is reduced much more than the bulk modulus under the western region[14], which would be the case if partial melting were present in the upper mantle there. Seismic refraction shows that the uppermost mantle, just under the crust, transmits P_n waves with lower velocities in the western region than in the craton, with the lowest velocities in the Basin and Range Province. Results from long seismic refraction lines show the presence of a marked low-velocity layer for P waves in the upper mantle under the western region[15–17], but not under the craton. In a representative recent model[18], the low-velocity layer lies in the depth range 65–200 km. Recent studies of attenuation of P and S teleseismic waves[19] have confirmed large variations under the US, with greatest attenuation under the western region including, but not confined to, the Basin and Range Province, and lowest attenuation under the north central shield of the craton. Seismological studies, therefore, define a region in which the elastic body wave velocities are reduced, and their amplitudes attenuated through anelastic response, in a layer in the upper mantle under the western region, in general, and the Basin and Range Province, in particular.

Observations of natural time variations of the geomagnetic field, with two-dimensional arrays of recording magnetometers, can be used to discover and map rock structures of anomalously high electrical conductivity[20]. Figure 1 summarizes the results of the first three such studies with arrays of magnetometers[21–24]. The density of stippling on the map gives a qualitative indication of the conductance (=conductivity × thickness) of the anomalously conductive layer. This is confined to the region west of the craton, with high conductance under the Basin and Range Province and the Colorado Plateau, and still higher conductance under the Southern Rockies and Rio Grande Rift (where Schmucker[25] first found a highly-conductive ridge in the upper mantle) and under the Wasatch Front mountains of Utah. The magnetovariation fields alone give poor discrimination in depth, and other physical parameters are usually invoked to constrain the depths of models of conductivity. Figure 1 (inset) shows a model obtained by Porath[26] on the assumption that the conductive layer is identical with the seismic low-velocity layer. It shows one, non-unique model which fits the magnetovariation fields along the section SS at latitude 38° N. The section and map can be used together to gain an impression of conductive structure under the western region. Recent magnetotelluric soundings[27,28] have verified that high conductivities occur at lower crustal depths, in general agreement with the section shown.

I have shown elsewhere[29] that the electrical conductivity distribution is highly correlated with heat flow and with the seismic low-velocity, high-attenuation layer. The conductivities required to model the magnetovariation fields are very high, and consistent with ionic conduction in a melt fraction in interconnected rock pores[30]. While there are several other ways in which rocks can be highly conductive[31], in the western US the close association of electrical conductivity with the seismic low-velocity layer, and with high heat flow, makes it very probable that the conductive layer is, in fact, a layer of the uppermost mantle containing a molten mineral fraction[32]. It is thus reasonable to regard Fig. 1 as a map and section of partial melting in the uppermost mantle. Shankland and others[33] have examined the properties required in a porous rock containing a melt fraction, to account for the electrical conductivities and seismic parameters observed.

Thus, there is substantial evidence for widespread partial melting in a layer, roughly 150 km thick, in the upper mantle under much of the US in a region bounded to the east by the east front of the Rocky Mountains and to the west by the Sierra Nevada. Furthermore, in this layer the rigidity modulus and estimates of Q are reduced, compared with the craton. As a first approximation, the crust and the lithosphere may be treated as equivalent in the region of partial melting, and are represented as such in Fig. 3.

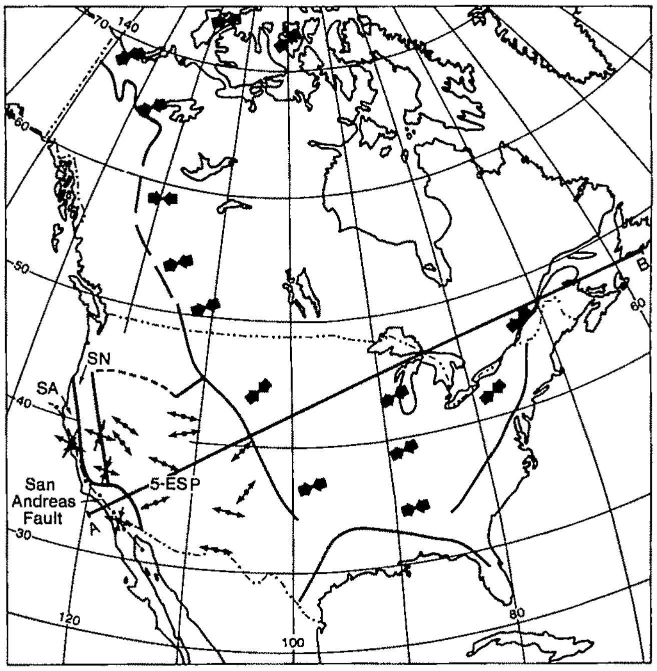

Fig. 2 Stress orientations in North America. Pairs of broad arrows show the directions of the greater horizontal principal stress in the craton. Two-headed arrows indicate the directions of the lesser horizontal principal stress in five extensional stress provinces (5-ESP). SN, Sierra Nevada stress province; SA, San Andreas stress province. Data sources: US and eastern Canada, ref. 37; western Canada, ref. 42; Arctic Islands, ref. 49. AB marks the great circle of the section in Fig. 3.

Mass transport of heat by an upflow of mantle material, formerly under the EPR and now under the continent, provides an explanation of all of the phenomena discussed above. However, heat was carried up in ascending melt from the former subduction, until about 20 Myr ago. There is now a crust ~30 km thick which can transmit heat only by conduction, and its thickness may have varied with time. It is therefore difficult to show that the existing layer of partially molten rock could not be a remnant from melt which came up from the plate before subduction ended. The change in character of the volcanics, from andesitic to basaltic composition, is difficult for proponents of the 'remnant' view but is not in itself conclusive. An entirely different line of evidence has become available which, I believe, resolves the ambiguity.

Stress orientations in North America

The orientation of the stress tensor in the Earth's crust, within a tectonic plate, contains important information on the forces driving that plate. In general, one principal stress is approximately vertical, that is, normal to the free surface; and fractures produce normal faults if σ_1 is vertical, strike-slip faults if σ_2 is vertical and thrust faults if σ_3 is vertical[34], where $\sigma_1 \geq \sigma_2 \geq \sigma_3$ are the principal stresses. For plate tectonics, special interest lies in the orientation and magnitudes of the two horizontal principal stresses, denoted S_H and S_h, with $S_H \geq S_h$. Crustal stress can be investigated by means of field studies of recent movements on faults and of igneous intrusions[35], and through overcoring strain relief techniques, hydraulic fracture experiments and earthquake source mechanisms[36]. Using these methods in a study of crustal stress in the conterminous United States, Zoback and Zoback[37] have delineated 14 stress provinces. Within each province the directions and relative magnitudes of the horizontal principal stresses are nearly constant. The largest of these is their Mid-Continent Stress Province, which extends from the east front of the Rocky Mountains of Colorado and Wyoming to New England and the Atlantic provinces of Canada.

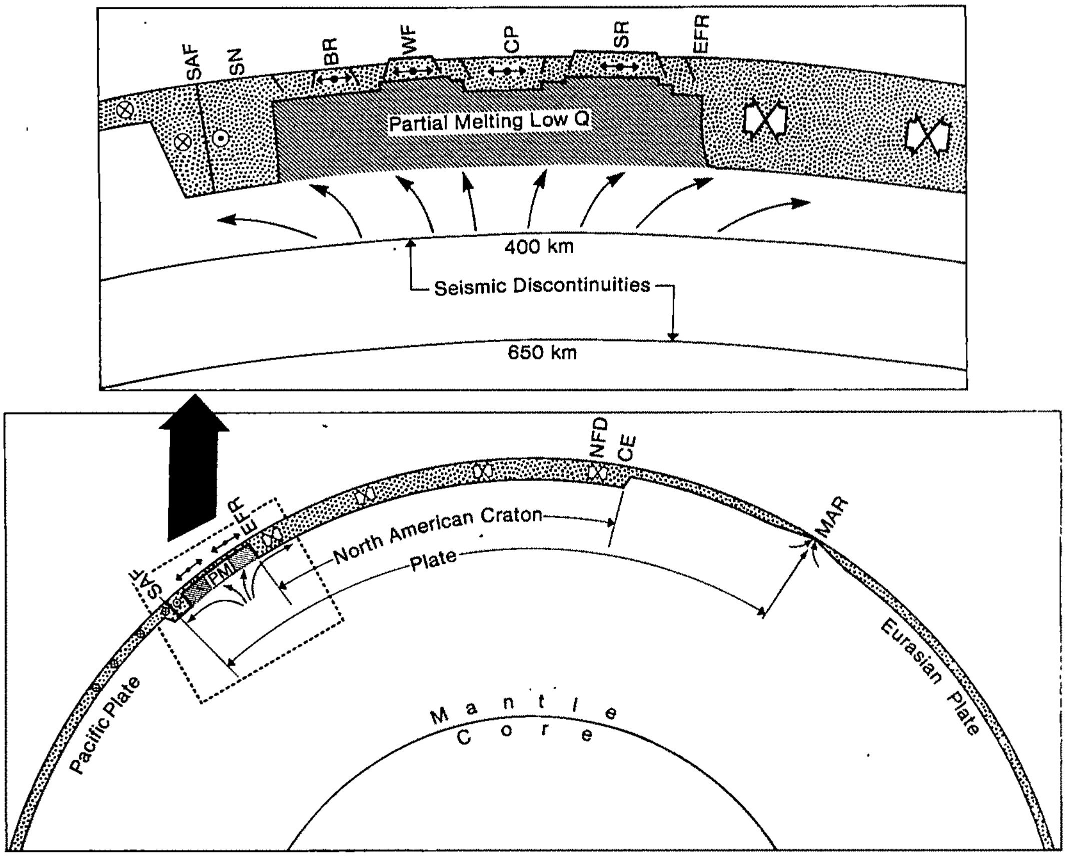

Fig. 3 A cartoon section, without radial exaggeration, along great circle AB in Fig. 2. The lithosphere is stippled. Stress symbols correspond to those in Fig. 2. SAF, San Andreas Fault; EFR, East Front of the Southern Rocky Mountains; NFD, Newfoundland; CE, continental edge; MAR, Mid-Atlantic Ridge. In the inset, SN, Sierra Nevada; BR, Basin and Range Province; WF, Wasatch Front; CP, Colorado Plateau; SR, Southern Rockies.

This province is characterized by a NE–SW direction of S_H, which is often greater than the vertical stress[37–40]. Recently, this stress province has been shown to extend through the western Canadian sedimentary basin to the Arctic coast at the Mackenzie River delta, and is probably coextensive with the old craton of North America[41,42]. The extension has been made through the recognition that a class of fractures in the walls of oil-wells, known as breakouts[43,44], are shear fractures which result from amplification by the oil-well of the stress difference in a stress field with $S_H \neq S_h$ (refs 45–47). According to this hypothesis[45,46], the fractures elongate the section of the borehole with its long axis aligned with the lesser horizontal stress S_h. It has been verified by comparing the stress orientations from the breakouts with other indicators of stress orientation in five stress provinces[41,42,46–48], and is widely accepted.

Directions of S_H in the craton are shown in Fig. 2 by pairs of arrows: each pair represents between 3 and 30 stress directions. Cox[49] has given breakout orientations from 15 oil wells in the Arctic Archipelago, of which 13 show the same NE–SW orientation of S_H as elsewhere in the craton. He has also determined the azimuths of breakouts in numerous wells in Quebec, which give S_H directions similar to the most easterly pair of arrows in Fig. 2.

The North American craton is under a stress field with remarkably uniform NE–SW orientations of S_H. As remarked elsewhere[37,42], this strongly suggests northeastward traction on the base of the plate. Such traction would arise if the plate were sliding to the south-west and experiencing viscous drag from a passive asthenosphere[37], or if northeastward flow in the underlying mantle were pushing the plate, again by viscous drag[42]. The latter case would apply if a divergent upcurrent were present in the mantle beneath the region west of the Rocky Mountains. The stress orientation in the craton cannot discriminate between these two possibilities.

The key to the problem is provided by the stress field in the region between the east front of the Rocky Mountains and the Sierra Nevada. Double-headed arrows in Fig. 2 represent directions of S_h, each from several stress orientations given by Zoback and Zoback[37], in five of their stress provinces showing east–west extensional stress. These extensional stress provinces include the Basin and Range, Colorado Plateau and Rio Grande Rift. In all of them the dominant fault type is normal, which requires σ_1 to be vertical and $\sigma_3 \equiv S_h$. It is not implied that east–west tensile stress exists except very near the surface; σ_3 is probably a small compression in most localities. A normal-fault type of stress field is what is required for uplift of the Colorado Plateau and Southern Rockies, and for development of the horst and graben topography of the Basins and Ranges.

This normal-faulting, extensional stress field is also what would be expected above an upcurrent in the mantle. It is, in fact, the stress field in the oceanic crust at ridges. Figure 3 shows an attempt to present this visually, for which purpose I have assumed lithosphere thicknesses of 250 km under the craton and 70 km below the sea floor. The thick cratonic lithosphere is controversial but the present argument does not depend on it. In the western region I suggest, in Fig. 3, that the seismic low-velocity, electrical high-conductivity uppermost mantle has reduced strength, and is essentially part of the asthenosphere. This is probably too simple but again is not essential to the argument.

The extensional stress field, between the Great Plains and the Sierra Nevada, cannot be understood by assuming that the North American plate is sliding over a passive asthenosphere to the south-west. On that model one would expect NE–SW compression to continue to the vicinity of the Sierra Nevada or even to the San Andreas fault system. Indeed if the lithosphere is thin above the western region (as shown in Fig. 3) one would expect the concentration of stress in it to produce increased NE–SW compression there. Instead, there is an extensional stress field. This requires vertical pressure from below which makes σ_1 vertical in the crust, as observed. Note that upward pressure exists now, as stresses propagate with the speeds of seismic waves. While the melt in the upper mantle could conceivably be a remnant from the subduction regime, say 25 Myr BP, it is difficult to believe that the uplift stress from such a melt remnant would not have been relieved in 25 Myr when postglacial isostatic rebound times are shorter by a factor of 1,000.

The change from andesitic to basaltic volcanics ~25 Myr ago fits the hypothesis that a mantle upcurrent was overridden by the continent then. The stress pattern indicates that there is now upward pressure. Recent evidence[50] from surface wave velocities indicates low velocities of vertically polarized shear waves at depth 250 km under the presently spreading EPR and the San Andreas and Queen Charlotte Islands transform fault regions, with resolution insufficient to discriminate between the San Andreas fault and the Basin and Range Province. These three observations strongly support continuing mantle upflow under the continent. Other evidence, noted earlier, strongly suggests such upflow but can be explained otherwise.

Implications for plate dynamics

The prime question for plate dynamics is what form convection takes. Even if the plates slide over a passive asthenosphere, propelled by gravity sliding[51] from the ridges ('ridge push') and, where there is a subducted leading edge which has not reached 650 km depth, by the excess weight of the subducted plate[52] ('trench pull') there is convection with some undefined return path. This simplest model cannot, however, account for the persistence of upflow under western North America.

Convection in the mantle is required to move the plates and various types are under examination. Simplicities in the distribution of the tectonic plates[53] and in geoid highs and lows[54–56] suggest deep mantle circulation, and whole-mantle convection is a model still favoured by some[57]. However several lines of geochemical and geophysical evidence increasingly indicate a stratified mantle with change of chemical composition at the seismic discontinuity near depth 650 km (refs 58–62). Whereas convection may be expected both below and above the 650-km level, the two convective patterns may be independent or weakly coupled[56]. Clearly, the upper mantle circulation will be of greater relevance to plate dynamics. Many models of convection in a 650-km layer describe square cells of comparable width which could not drive a plate thousands of kilometres wide. However, Houseman has shown[63] that convection cells of large width-to-depth ratio are possible if they are driven by a horizontal temperature difference such as would be expected between the mantle beneath an ocean ridge and a subduction. Anderson[58] has suggested alternatives to the various simplifying assumptions often adopted on convection. He suggests that melting may be more effective in producing the density change that drives convection rather than thermal expansion.

Evidence has been presented to show that an upward flow in the upper mantle, formerly under the EPR, is now under the Basin and Range and Colorado Plateau region of western North America. The mantle upflow may extend to western Canada, and the strip of low S_V velocity in Anderson's tomographic maps[50] suggests that it does. This would be consistent with the uniformity of stress orientation in the craton into the Arctic islands (Fig. 2). If the mantle upflow is present as I have argued, there are two points of interest related to convective models.

First, the upflow continued while the subducted plate (now the root of the Sierra Nevada) passed over it. It must, therefore, come from a depth near the 650 km discontinuity, as a minimum.

Second, the convective circulation has survived the effects of the continent overriding its upward limb for ~25 Myr. If one applies Houseman's type of convection, the operative temperature difference is that between colder mantle below the subductions on the north-west side of the Pacific, and hotter mantle, formerly below the EPR, now below western North America. Note that the upflow is not under the craton, whose great thickness of poorly-conducting lithosphere would probably change the flow rapidly[58]. With the thin crust of the Basin and Range Province as conductive cover, the upflow may have boundary conditions not too different from those of the Rise sea floor.

It is not implied that all ocean ridges lie above convective upcurrents in the mantle. Spreading rates of ridges vary, and *a priori* it seems possible that fast-spreading ridges such as the EPR lie above divergent mantle flow which drives them; whereas slowly-spreading ridges like the Mid-Atlantic Ridge may not be driven and may approximate to the pull-apart model. Gravity sliding will operate in both types, and even under a passive ridge partial melt will ascend, because its density is less than the mean value for the upper mantle, to form new lithosphere. In this case, however, the flow beneath the ridge will be convergent and only the sliding lithosphere itself exhibits divergent motion.

Conclusions

Observations of topography, seismology, heat flow, electromagnetic geophysics, petrochemistry and the orientation of the stress tensor in the crust, combine to support the view that an upcurrent exists in the mantle below western North America. This, in turn, implies that during the Tertiary, the EPR was a ridge of the active type, driven by a divergent upcurrent in the underlying mantle. Other ridges are probably of the passive type, but this has not been demonstrated.

For plate dynamics, a principal implication is that at least some tectonic plates are actively driven by mantle circulation. An interesting possibility is that the Pacific Plate is being driven by mantle convection towards the subductions which form its northwestern boundary. In such a system, if substantiated, the upward limb of the convection would lie under the EPR of southern and tropical latitudes, and under western North America.

I thank W. I. Gough for many discussions during the development of the ideas in this paper. This research has been supported by the Natural Sciences and Engineering Research Council of Canada.

Stimulation of 3T3 cells induces transcription of the c-*fos* proto-oncogene

Michael E. Greenberg & Edward B. Ziff

Kaplan Cancer Center and Department of Biochemistry, New York University Medical Center, 550 First Avenue, New York, New York 10016, USA

*Transcription of the c-*fos *proto-oncogene is greatly increased within minutes of administering purified growth factors to quiescent 3T3 cells. This stimulation is the most rapid transcriptional response to peptide growth factors yet described, and implies a role for c-*fos *in cell-cycle control. Transformation by c-*fos *may result from a temporal deregulation of this control.*

ABERRANT expression of a variety of normal cellular genes (proto-oncogenes) can transform a normal cell into a tumour cell[1–3]. Several of these genes encode protein products which are homologous to either a growth factor or a growth factor receptor. For example, the *sis* oncogene of the simian sarcoma virus displays striking homology with platelet-derived growth factor (PDGF)[4,5], a small polypeptide that stimulates the growth of connective tissue cells[2]. A portion of the sequence of the epidermal growth factor receptor is virtually identical to another oncogene (*erb-B*) carried by avian erythroblastosis virus[6]. Moreover, several growth factor receptors, including those for PDGF[7–9], epidermal growth factor (EGF)[10,11] and insulin[12,13], as well as 10 different oncogene protein products[3], share functional homology in that they are all associated with tyrosine kinase activity.

Much of the information about growth factors and their receptors has been obtained by stimulating BALB/c-3T3 fibroblast cells whose growth has been arrested by serum starvation to undergo a synchronous progression through the cell cycle by the addition of serum[14]. In the absence of serum, 3T3 cells enter a state (G_0) in which cell division and growth stop and many metabolic processes are reduced[1]. The addition of serum initiates a complex series of events (G_1 phase), which culminates 14–20 h later in DNA synthesis (S phase) and cell division[14]. PDGF is the serum component that renders 3T3 cells competent to undergo DNA synthesis[15–18], although additional components such as EGF and the somatomedins (progression factors) seem to be necessary to maintain cell viability[19–23]. PDGF interacts with the external surface of cells by binding to a specific receptor protein in the plasma membrane[24] which activates a receptor–associated tyrosine kinase activity[7–9,25]. Almost nothing is known, however, about the mechanisms by which these membrane changes lead to nuclear events such as the activation of specific cell-cycle genes and ultimately DNA replication.

The availability of cloned DNA probes for a variety of cellular genes has made it possible to examine the transcriptional events resulting from growth factor stimulation. Several virally encoded transforming proteins have normal cellular homologues that function in cell-cycle regulation[4–6], suggesting that in general, proto-oncogenes might be involved in cell-cycle control. Such a possibility is supported by recent experiments[26,27] demonstrating a cell-cycle dependence of the expression of the proto-oncogene c-*myc* mRNA. This gene encodes a nuclear protein[28] whose abnormal expression has been implicated in a wide variety of naturally occurring tumours[29–37].

The c-*onc* genes, particularly those encoding nuclear antigens, might be differentially regulated at the transcriptional level during cell-cycle progression. We therefore examined the extent of transcription of 17 different c-*onc* genes as a function of their position in the cell cycle, using a nuclear run-off transcription assay[38,39]. We report here that stimulation of BALB/c-3T3 cells with defined growth factors induces a rapid transient increase in the transcription of the proto-oncogene c-*fos*, the normal cellular homologue of the transforming gene of FBJ-osteosarcoma virus[40–42]. c-*fos* is a nuclear protein[43] of unknown function which is expressed at high levels in extra-embryonal tissues[44,45].

Analysis of c-*onc* transcription

We measured the effect of a mitogenic signal on the transcription of a range of different c-*onc* genes using isolated nuclei from BALB/c-3T3 cells (Fig. 1). The nuclear run-off transcription assay was used to measure the level of transcription of specific genes in a variety of cell types[39,40,46–50]. In this assay, new RNA transcripts are not initiated, but transcripts which are already initiated are faithfully elongated, giving a reasonably accurate measure of the level of transcription at the time of cell lysis[38,39,51].

Nuclei isolated from BALB/c-3T3 cells between 0 and 24 h after serum stimulation show a striking increase in the transcription of two genes, c-*fos* and actin, within 15 min of the initial stimulation of quiescent BALB/c-3T3 cells (Figs 1*a*, 2). c-*fos* transcription transiently increases more than 15-fold very soon after stimulation, returning to its initial levels within 30 min. No further changes in c-*fos* transcription are observed as the 3T3 cells continue to progress through the cell cycle from G_1 to S phase. The alteration in actin transcription appears more complex. The initial increase and subsequent decrease in actin transcription parallels that of c-*fos*. After about 60 min, however, actin transcription begins to increase again (Fig. 1*a*). This increase may correspond to the actin mRNA increase seen within 4 h of serum addition to growth-arrested 3T3 cells[27,52]. These initial experiments use an actin cDNA plasmid that does not distinguish which of the several different cross-hybridizing actin genes[53,54] display the cell-cycle dependent regulation of expression.

We also observe a small but reproducible increase in c-*myc* transcription after serum stimulation (Figs 1*a*, 2), which peaks approximately 2 h after stimulation and decreases significantly within 4 h. This experiment suggests that the previously reported growth-factor induced changes in c-*myc* mRNA[26,27] are at least in part controlled at the level of transcription. In addition, the transcription of c-*myb* (encoding another nuclear antigen[55]) appears to increase in parallel with c-*myc* (Fig. 1*a*). This result is inconclusive, however, because the c-*myb* plasmid DNA that was used, pVM2, also contains flanking cellular and viral sequences.

The increases in the transcription of c-*fos* and actin precede

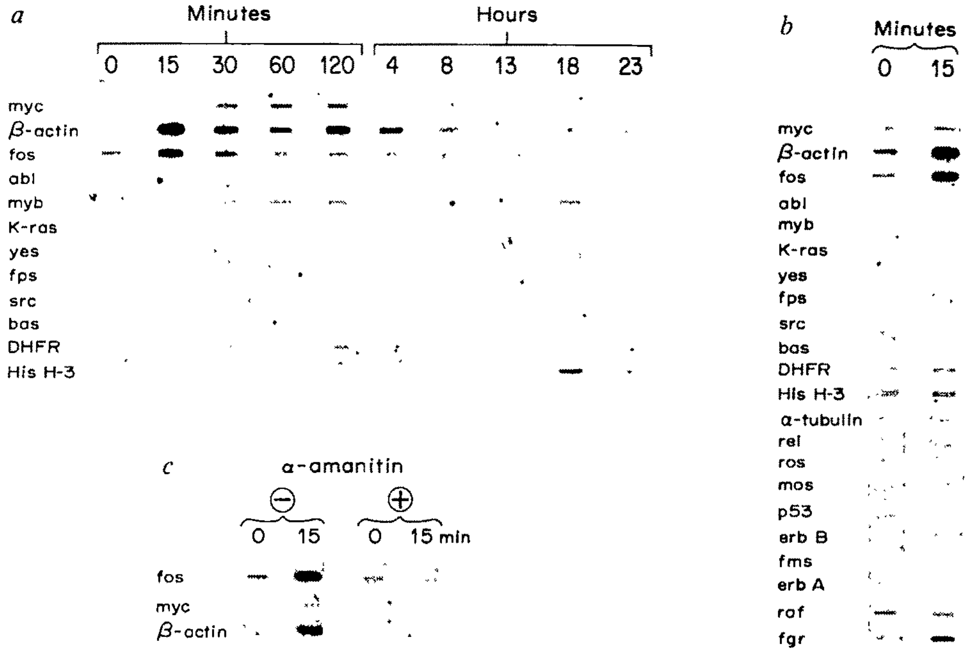

Fig. 1 Transcriptional analysis of c-*onc* genes after stimulation of BALB/c-3T3 cells. c-*onc* gene plasmids bound to nitrocellulose were hybridized with ^{32}P-labelled run-off transcripts from nuclei isolated at different times after serum addition to confluent, growth-arrested BALB/c-3T3 cells. ***a***, 23-h time course experiment analysing the transcription of 12 different genes. Increased transcription of c-*fos* and β-actin occurs within 15 min of serum addition, increased c-*myc* transcription occurs after 2 h and increased histone H3 transcription after 18 h. The changes in transcription are not due to hybridization of labelled RNA transcripts to non-specific DNA such as pBR322 sequences. No significant hybridization of ^{32}P-labelled RNA was detected for *onc* plasmid DNAs such as v-*abl* which contains a complete sequence of pBR322. Furthermore, when c-*fos* and actin sequences were cleaved from the pBR322 vector with restriction enzymes, Southern blotted and probed with ^{32}P-labelled RNA transcripts, significant hybridization to c-*fos*- or actin-specific fragments was detected but no hybridization to pBR322 sequences occurred (data not shown). The possibility that the actin and c-*fos* transcription signal is the result of cross-hybridization between these two genes was ruled out by a competition experiment in which preincubation of ^{32}P-labelled run-off transcripts with the actin plasmid, did not deplete the level of RNA transcripts hybridizing to pv-fos-1 (data not shown). ***b***, Analysis of the transcription of 22 different genes in growth-arrested 3T3 cells (0) and cells stimulated with calf serum for 15 min (15). ***c***, Transcription of c-*fos*, c-*myc* and β-actin was measured in isolated nuclei in the presence (+) or absence (−) of 1 μg ml^{-1} α-amanitin. Nuclei were isolated from growth-arrested 3T3 cells (0) or 3T3 cells stimulated with calf serum for 15 min (15).

Methods: Cell culture: BALB/c-3T3 A31 cells obtained from the American Type Culture Collection were passaged to a density of 9×10^5 cells per 175-cm^2 tissue culture flask in 25 ml Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% calf serum (Gibco), and allowed to grow to confluence over a period of 7–8 days at 37 °C, 10% CO$_2$. After 7 days in culture, the confluent monolayers had depleted the medium of serum growth factors and the 3T3 cells had growth arrested and entered a G$_0$ state as described previously[14]. The cells were then stimulated to progress synchronously through the cell cycle by removing the depleted medium and replacing it with fresh DMEM containing 15% calf serum. Early passage BALB/c-3T3 cells were used for all experiments. Nuclear run-off transcription assay: Medium was removed from one 175 cm^2 tissue culture flask of BALB/c-3T3 cells, the cells were washed three times with ice-cold phosphate-buffered saline (PBS), scraped in PBS and pelleted at 500*g* for 5 min. The cell pellet (1×10^7 cells) was resuspended in 1 ml NP40 lysis buffer (10 mM Tris-HCl *p*H 7.4, 10 mM NaCl, 3 mM MgCl$_2$, 0.5% (v/v) NP40), incubated for 5 min on ice and centrifuged at 500*g* for 5 min. The supernatant was removed and used for the isolation of polyadenylated RNA. The nuclear pellet was washed once with 2 ml NP40 lysis buffer and centrifuged at 500*g*. The supernatant was discarded, the nuclei were resuspended in 100 μl 50 mM Tris-HCl *p*H 8.3, 40% (v/v) glycerol, 5 mM MgCl$_2$, 0.1 mM EDTA and frozen in liquid N$_2$. The nuclei were thawed for the run-off transcription assay and mixed with 100 μl reaction buffer (10 mM Tris-HCl *p*H 8.0, 5 mM MgCl$_2$, 300 mM KCl, 0.5 mM each of ATP, CTP, and GTP and 100 μCi of [α-^{32}P] UTP (760 Ci mmol^{-1}, NEN) and reacted at 30 °C for 30 min. The ^{32}P-labelled RNA was isolated as described elsewhere[39] with different conditions for hybridization to filters. Before ethanol precipitation, ^{32}P-labelled RNA was treated with a final concentration of 0.2 M NaOH for 10 min on ice. The solution was neutralized by the addition of HEPES (acid free) to a final concentration of 0.24 M and the RNA was precipitated with ethanol. After centrifugation, the ^{32}P-labelled RNA pellet was resuspended in 10 mM *N*-tris(hydroxymethyl)methyl 2-aminoethanesulphonic acid (TES), *p*H 7.4, 0.2% SDS, 10 mM EDTA at 5×10^6 c.p.m. ml^{-1}. This RNA solution was mixed with an equal volume of 10 mM TES *p*H 7.4, 0.2% SDS, 10 mM EDTA, 600 mM NaCl and 2 ml of the RNA solution was hybridized at 65 °C for 36 h to DNA immobilized on nitrocellulose. In a given experiment, each filter was hybridized with the same number of c.p.m. ^{32}P-labelled RNA. After the hybridization the filters were washed with several changes, 2×SSC (1×SSC = 0.15 M NaCl, 0.0125 M Na citrate *p*H 7) for 2 h at 65 °C and incubated at 37 °C in 2×SSC with 10 μg ml^{-1} RNase A for 30 min. The filters were then washed again in 2×SSC at 37 °C for 1 h, air dried and exposed to Kodak SB-5 X-ray film. For binding to nitrocellulose, plasmids were linearized by restriction enzyme digestion and the DNA was denatured by incubation with 0.2 M NaOH for 30 min at room temperature, followed by neutralization with 10 volumes of 6×SSC. The DNA was spotted onto nitrocellulose using the Schleicher and Schuell slot blot apparatus. 10 μg DNA was applied per slot. The plasmids used were provided by Dr Inder Verma (pvfos-1, v-*fos*[61]), Dr Larry Kedes (human β-actin-1, β-actin[54]), Dr Kenneth Marcu (pM-c-*myc*-54, c-*myc*[62]), Dr David Baltimore (pAB3sub3, v-*abl*[72]), Dr J. Michael Bishop (pVM 2, v-*myb*[72]; perb-A, v-erb-A[74], perb-B probe F, v-erb-B[74], pSRA, v-*src*[75]), Dr Edward Scolnick (Merck, Sharpe and Dohme) (pHiHi-3, v-Ki-*ras*[76]), Dr Hidesaburo Hanafusa (pFSV, v-*fps*[77]), Dr George Vande Woude (pMS1, c-*mos*[78]), Dr Howard Temin (peco-rel, v-*rel*[79]), Dr Keith Robbins (pv-fgr1000, v-*fgr*[80]), Dr Lui-Hai Wang (pv-ros, v-*ros*[81]), Dr U. Rapp (pv-rafE-H, v-*raf*[82]), Dr Charles Scherr (pSM3, v-*fms*[83]), Dr Steven Tronick (pHB1, v-*bas*[84]), Dr M. Yoshida (pY73, v-*yes*[85]), Dr Nicholas Cowan (pmcα-1, α-tubulin, unpublished), Dr Arnold Levine (pp53-208, p53[86]), Dr Robert Schimke (pDHFR11, dihydrofolate reductase[87]) and Dr Nathaniel Heintz (pHh5B, hisH-3[88]).

that of c-*myc* (Fig. 1) and occur during the time interval in which the 3T3 cells are becoming growth-factor independent[19,22,23]. All these changes occur as the 3T3 cells progress from G$_0$ to G$_1$ and before the initiation of cellular DNA synthesis at ~14 h after serum stimulation, measured by the incorporation of ^{3}H-thymidine into trichloroacetic acid (TCA) precipitable counts (Fig. 2). In similar conditions many other c-*onc* genes including c-Ki-*ras* whose viral counterpart encodes a GTP binding protein[56,57] and c-*abl* which encodes a tyrosine kinase[58], displayed barely detectable levels of transcription at all times after serum stimulation (Fig. 1*a*). Other sequences such as those for α-tubulin were transcribed at a low but constant level throughout the cell cycle and the transcription of the histone H3 gene was observed to increase at the time of DNA synthesis as reported previously (Fig. 1*a*)[47–49].

When 22 different genes were tested (Fig. 1*b*) only 3, c-*fos*, actin and an additional gene, c-*fgr* (ref. 59), exhibited a change in transcription 15 min after serum stimulation. c-*fgr* is the

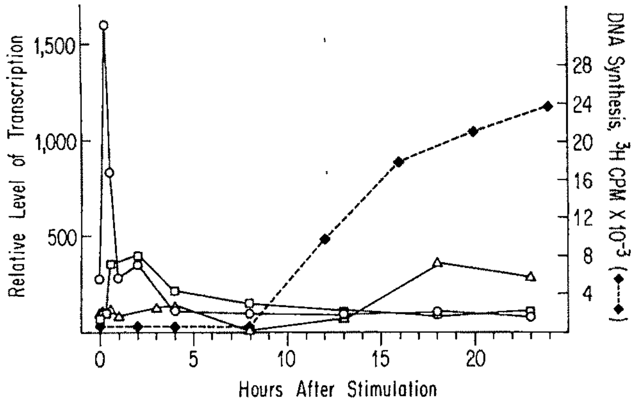

Fig. 2 Quantitation of transcriptional activation after stimulation of BALB/c-3T3 cells. The relative amounts of ^{32}P-labelled nuclear run-off transcripts hybridized to c-*fos* (○), c-*myc* (□) and histone H3 (△) plasmids bound to nitrocellulose, were determined by quantitative densitometric scanning of autoradiographs from Fig. 1*a*[89] (arbitrary units). DNA synthesis was measured after stimulating growth-arrested BALB/c-3T3 cells to divide by the addition of 15% calf serum as described in Fig. 1 legend. The incorporation of [*Me*-^{3}H]thymidine into DNA (■) was measured by pulse labelling cells with 90 μCi [*Me*-^{3}H]thymidine (2.0 Ci mmol^{-1}) for 2 h at the indicated times after serum stimulation. The medium was removed, cells washed three times with ice-cold PBS, and lysed with 0.2 M NaOH. An aliquot of the cell lysate was precipitated with TCA, collected on Whatman GF/A glass fibre filters and counted in toluene/omnifluor scintillation fluid. In all the experiments reported in Figs 1–6, serum stimulation of quiescent BALB/c-3T3 cells resulted in a 20–80-fold increase in the incorporation of ^{3}H-thymidine into TCA precipitable counts.

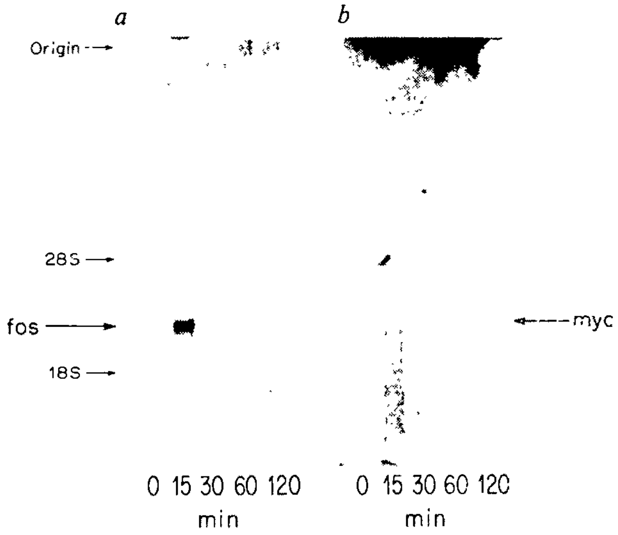

Fig. 3 Kinetics of c-*fos* and c-*myc* mRNA induction after serum stimulation of BALB/c-3T3 cells. Polyadenylated cytoplasmic RNA from 3T3 cells, isolated at various times after serum stimulation, was fractionated on a formaldehyde–agarose gel, transferred to nitrocellulose, hybridized with ^{32}P-labelled pv-fos-1 (*a*) or pM-c-myc-54 (*b*) plasmids, and after washing exposed to SB-5 X-ray film. **Methods:** Polyadenylated RNA was isolated from the post-nuclear supernatant (see Fig. 1 methods). The supernatant (4 ml, from 4×10^7 cells) was mixed with 0.2 ml 0.2 M vanadyl ribonucleoside complex (BRL) and centrifuged at 10,000*g* for 10 min at 4 °C. The supernatant was then mixed with 4 ml 0.2 M Tris-HCl *p*H 7.5, 0.44 M NaCl, 2% SDS, 25 mM EDTA containing 0.8 mg proteinase K (Worthington) and incubated at 37 °C for 30 min. After phenol and chloroform extractions, RNA was precipitated with ethanol. Pelleted RNA was resuspended in 10 mM Tris-HCl *p*H 7.4, 10 mM EDTA, 0.2% SDS, denatured by heating to 65 °C for 5 min and RNA (~50 μg) applied to a 0.5-ml poly(U) Sepharose column as described previously[90]. The polyadenylated RNA was fractionated on a 1% formaldehyde agarose gel and transferred to nitrocellulose following the procedure of Cheng-Kiang *et al.*[91]. The RNA bound to nitrocellulose was prehybridized overnight with buffer containing 1% glycine, 50% formamide, 5×SSC, 50 mM NaH_2PO_4 *p*H 6.5, 250 μg ml^{-1} sonicated salmon sperm DNA, 1 × Denhardt's solution (1% Ficoll, 1% polyvinylpyrrolidone, 1% bovine serum albumin). The hybridization was carried out for 12–16 h in 10 ml 50% formamide, 2×SSC, 40 mM NaH_2PO_4 *p*H 6.5, 200 μg ml^{-1} salmon sperm DNA, 0.8×Denhardt's, 10% dextran sulphate, 10 mM EDTA, 0.1% SDS, with 1×10^8 c.p.m. ^{32}P-nick-translated plasmid (4×10^8 c.p.m. per μg DNA)[92].

normal cellular homologue of v-*fgr*, the transforming gene of Gardner–Rasheed feline sarcoma virus. The v-*fgr* DNA we used as a probe is a hybrid gene containing a portion of actin as well as a tyrosine kinase sequence[60]. Therefore, the increased hybridization in the v-*fgr* slot (Fig. 1*b*) probably reflects increased actin transcription. c-*fgr* tyrosine kinase gene transcripts may, however, also change.

Several control experiments were performed to establish the fidelity of the run-off transcription assay. The increased transcription of c-*fos* and actin within 15 min of serum addition is not simply due to an increase in overall transcription efficiency, because the transcription of a variety of other genes is unaffected by serum stimulation (Fig. 1*b*). Also, no reproducible differences in the total number of counts incorporated into RNA in isolated nuclei are observed during progression of 3T3 cells through the cell cycle (data not shown). Genes such as histones and actin display a cell-cycle dependent change in transcription consistent with previous results[27,47–49,52], further indicating that the isolated nuclei retain their transcriptional fidelity. The increased c-*fos*, c-*myc* and actin transcription seems to be the result of increased RNA polymerase II utilization, as α-amanitin completely blocked the transcription of these genes (Fig. 1*c*).

The plasmids used to measure c-*fos* and c-*myc* were oncogene specific. The pv-fos-1 probe contains sequences entirely from the v-*fos* coding region and sequence homology to the corresponding c-*fos* sequences is >99%[42]. pv-fos-1 recognizes a unique *Eco*RI restriction fragment in mouse DNA[61], making it unlikely that our transcription assay has detected repetitive sequences due to cross-hybridization. Furthermore, the pv-fos-1 plasmid hybridizes to a discrete 2.2 kilobase (kb) mRNA which is the size of c-*fos* mRNA[44]. Moreover, c-*fos* lacks homology with any known cellular sequence[42], making it unlikely that the observed increase in the transcription of both c-*fos* and actin reflects a homology between these two genes as appears to be the case for actin and v-*fgr*.

It was more difficult to establish the specificity of the c-*myc* transcriptional signal. The pM-c-myc-54 plasmid used to measure c-*myc* transcriptional levels is a mouse cDNA, composed of the three c-*myc* exons inserted into the *Pst*I site of pBR322[62]. This plasmid recognizes a c-*myc*-specific fragment and two c-*myc*-homologous sequences[62]. Although it is possible that the increased transcription observed using the c-*myc* probe is a result of increased transcription from one of these homologous c-*myc*-like sequences, this appears unlikely as the pM-c-myc-54 plasmid detects a discrete c-*myc* mRNA of 2.4 kb which displays the expected cell-cycle dependent change in expression.

Stimulation of c-*fos*

To determine whether the increased transcription of specific genes after serum addition is followed by an increase in cytoplasmic mRNA, we isolated cytoplasmic RNA from quiescent and stimulated cells and analysed polyadenylated species (Fig. 3*a*). A prominent band of 2.2 kb appears 15 min after stimulation with a molecular weight equivalent to c-*fos* mRNA[44]. The 2.2 kb mRNA level is highest 15 min after serum addition and decreases below detection within 60 min; the half life is thus very short.

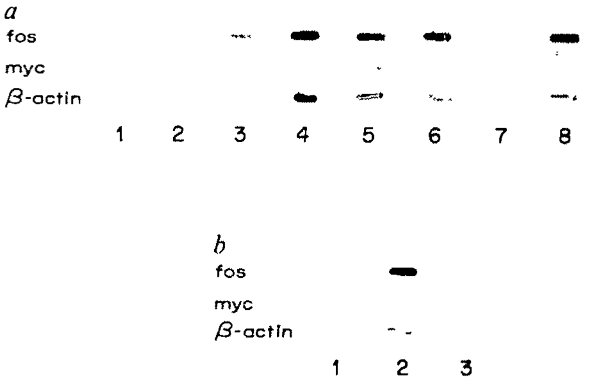

Fig. 4 Transcriptional activation after stimulation of BALB/c-3T3 cells with defined growth factors. 3T3 cells were grown to confluence and growth arrested as described in Fig. 1 legend. ***a***, The medium was removed and cells were incubated for 15 min with: lane 1, the same depleted medium; lane 2, DMEM without calf serum; lane 3, DMEM containing 0.5% calf serum; lane 4, DMEM containing 15% calf serum; lane 5, DMEM containing 2.5 U ml^{-1} partially purified porcine PDGF (Speywood); lane 6, DMEM containing 0.1 $\mu g\,ml^{-1}$ fibroblast growth factor (Collaborative Research); lane 7, DMEM containing 10 $\mu g\,ml^{-1}$ insulin (Sigma); lane 8, DMEM containing 0.26 $\mu g\,ml^{-1}$ TPA (Sigma). ***b***, The medium was removed and cells were incubated for 15 min with: lane 1, the same depleted medium; lane 2, DMEM containing 1.0 unit ml^{-1} homogeneous porcine PDGF; lane 3, DMEM containing 0.1 $\mu g\,ml^{-1}$ EGF (Collaborative Research). After stimulation with growth factor, cells were collected, nuclei isolated and run-off transcription assays performed. The ^{32}P-labelled RNA transcripts were hybridized with pv-fos-1, pM-c-myc-54 and pHβ-actin plasmids immobilized on nitrocellulose as described in Fig. 1 legend. The radioactivity was visualized by autoradiography. 1 U of PDGF is the amount of growth factor needed per ml of DMEM to yield 50% maximal incorporation of ^3H-thymidine into DNA in confluent growth-arrested Swiss 3T3 cells[93].

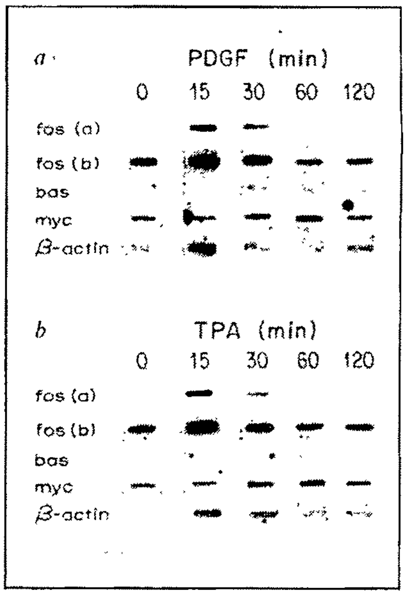

Fig. 5 Kinetics of c-*fos* transcriptional activation after stimulation of BALB/c-3T3 cells with PDGF and TPA. Nuclei were isolated from serum starved cells and 3T3 cells stimulated for 15, 30, 60 and 120 min with homogeneous porcine PDGF. *a*, 1 U ml^{-1} DMEM; *b*, TPA 0.26 $\mu g\,ml^{-1}$ DMEM. ^{32}P-labelled RNA transcripts were prepared as described in Fig. 1 legend and were hybridized with pv-fos-1, pbas, pM-c-myc-54 and pHβ-actin DNA immobilized on nitrocellulose. The radioactivity was visualized by autoradiography. c-*fos*(a) filters were exposed for 18 h; c-*fos*(b), c-*bas*, c-*myc* and β-actin filters exposed for 5 days.

The kinetics of c-*fos* mRNA induction are quite different from c-*myc*. Consistent with previous results[26,27], virtually no c-*myc* mRNA is detectable in the cytoplasm until 2 h after serum addition, at which point a substantial increase in the 2.4 kb c-*myc* mRNA (Fig. 3*b*) is observed.

We next tested the ability of specific purified growth factors to induce the transcription of the c-*fos* gene. When growth-arrested 3T3 cells are incubated in serum-free medium, no change in the level of c-*fos* transcription is observed (Fig. 4*a*, lane 2). If the serum-free medium is supplemented with various factors at concentrations that effectively generate the competence phase of the mitogenic response (Fig. 4)[19-22,63], a reproducible increase in c-*fos* transcription is observed within 15 min. Hormones that do not significantly stimulate competence in BALB/c-3T3 cells, but do maintain cell viability[21], cause no significant change in c-*fos* transcription (Fig. 4). In contrast with c-*fos*, the level of transcription of most other genes is not detectable after 15 min of treatment, although c-*myc* transcription is induced by PDGF and 12-*O*-tetradecanoylphorbol-13-acetate (TPA) within 1 h of growth factor addition (Fig. 5). Actin transcription is also stimulated with these purified factors in parallel with c-*fos* although the level of stimulation appears to be less than that observed using whole serum (Fig. 4). The kinetics of c-*fos* stimulation are identical when cells are treated with PDGF (Fig. 5*a*), TPA (Fig. 5*b*) or serum (Fig. 1*a*). The increased levels of c-*fos* nuclear transcripts are apparent as early as 5 min after serum addition; the c-*fos* transcription level peaks after 10 min, and begins to decrease by 15 min (Fig. 6).

Conclusions

The stimulation of c-*fos* transcription within 5 min of treatment of quiescent 3T3 cells with PDGF is the earliest transcriptional event known to occur in these cells in response to a growth factor; in other cells, factors such as glucocorticoid hormones have been shown previously to stimulate the transcription of murine mammary tumour virus genes with equally rapid kinetics[64].

The increased transcription of c-*fos* and c-*myc* genes is quickly followed by a substantial increase in the respective mRNAs. The transcriptional changes in c-*fos* and c-*myc* do not appear as large as the concomitant alterations in mRNA, perhaps because of differences in the sensitivity of the two assays, or because of changes in c-*fos* and c-*myc* mRNA stability. We have not established whether the cell-cycle dependent changes in expression result in comparable changes in the levels of the respective protein products. In the case of c-*fos*, this question is particularly significant because expression of the c-*fos* protein may be regulated by sequences at the 3′ end of the mRNA which, in some conditions, appear to inhibit translation of the RNA into protein[65].

The rapid activation and subsequent repression of c-*fos* transcription coupled with the short half life of the c-*fos* mRNA could explain why the mRNA is expressed during a very brief interval, ~30 min, of the G_0/G_1 transition and also why c-*fos* mRNA has been barely detectable in many nonsynchronized cell types[44]. If all cycling cells were to exhibit a transient increase in c-*fos* each time they pass through G_1, for a total of 15 min (~1/100th of the cell cycle), then in an asynchronous population of cells the levels of c-*fos* would be as much as 100-fold lower than the levels detected 15 min after synchronously stimulating cells to divide.

Our finding that the transcription of a proto-oncogene is rapidly stimulated in response to a growth signal raises questions about the role of this gene in the normal cell cycle, oncogenesis and transcriptional induction; for example, how a growth factor such as PDGF acts externally on the plasma membrane to induce gene transcription within 5 min. PDGF binding to its receptor activates a tyrosine kinase, which suggests that a protein modification such as phosphorylation could be involved in the transmission of the growth signal to the nucleus. This idea is

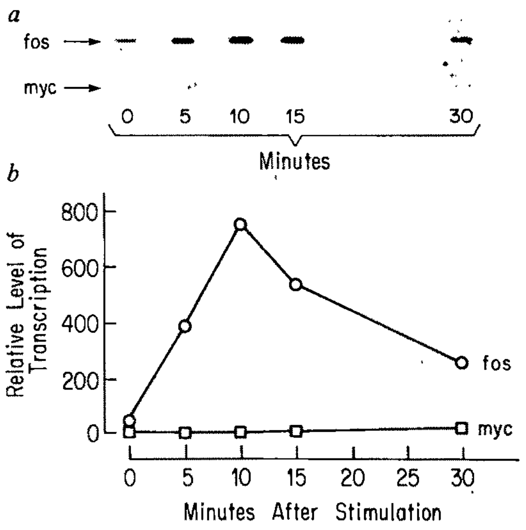

Fig. 6 Kinetics of c-*fos* transcriptional activation after serum stimulation of BALB/c-3T3 cells. Nuclei were isolated from serum starved 3T3 cells and from 3T3 cells stimulated with 15% calf serum for 5, 10, 15 and 30 min. ^{32}P-labelled RNA run-off transcripts were prepared as described in Fig. 1 legend and were hybridized with pv-fos-1, pM-c-myc-54 and pHβ-actin DNA immobilized on nitrocellulose. *a*, Radioactivity visualized by autoradiography; *b*, relative signal intensities calculated by densitometric scanning of the autoradiographs.

supported by the observation that TPA, which activates both protein kinase C[66,67] and tyrosine kinase[68–70], also activates c-*fos* and c-*myc* transcription.

Although the time course of activation of the c-*fos* and actin genes can be clearly distinguished from c-*myc*, it is not known whether c-*fos* or actin activation is a prerequisite for activating c-*myc* or other genes. PDGF induces c-*myc* mRNA levels even in the presence of protein synthesis inhibitors[26], suggesting that the prior stimulation of c-*fos* may not be required to induce c-*myc* transcription. Our kinetic experiments suggest that different factors may be involved in the regulation of c-*fos* and c-*myc* and that these genes may be members of two distinct classes of inducible genes. By differential screening of a cDNA library prepared from cells stimulated with PDGF for 4 h, a set of induced genes have been identified[71] into which c-*myc* may fall[25]. c-*fos* may be a member of a new class of early response genes, with actin and other unidentified genes; they could have a crucial role in committing a cell to enter G_1. Unlike c-*fos*, some of the genes might not produce a dominant transforming phenotype and therefore might not be detected by current assays for oncogenes.

We speculate that an early response gene such as c-*fos*, whose deregulation can result in cell transformation and uncontrolled proliferation, might be a gene that directly controls normal cell growth, for example by activating the cells' progression from G_0 into G_1. Nevertheless, a direct effect of c-*fos* expression on cell-cycle progression remains to be shown. The activation of c-*fos* may be necessary for commitment to DNA replication and cell division, but it appears not to be sufficient. c-*fos* transcription is activated by competence factors in the absence of progression factors (Fig. 4); these conditions will generate an initial mitogenic signal but are not sufficient to induce cellular DNA synthesis[19–22].

A variety of different mechanisms have been proposed to explain how normal cellular oncogenes might be altered so that they cause transformation, such as the overproduction of a normal gene or the mutation of a c-*onc* gene[3]. One proposal is that expression of high levels of c-*fos* protein in an inappropriate cell type might result in transformation[65]. Our finding that c-*fos* exhibits cell-cycle dependent changes in transcription supports a different possibility, that transformation by c-*fos* results at least in part from a deregulation of its temporal control. The expression of c-*fos* throughout the cell cycle rather than during a specific stage of the G_0/G_1 transition may be one mechanism of transformation. The continuous expression of c-*fos* might prevent a cell from ever entering a quiescent state, thus yielding a population of continually dividing cells.

We thank Drs Paul Stroobant and Michael Waterfield for providing the purified PDGF, Dr Robert Brackenbury for assistance with the densitometric scanning and Drs Nicholas Cowan and Peter D'Eustachio for their critical reading of the manuscript. This work was supported by ACS grant MV-75, and GM 30760 from the US NIH. E.B.Z. is the recipient of ACS Faculty Research Award FRA 207. M.E.G. was the recipient of a postdoctoral fellowship from the Damon Runyon-Walter Winchell Cancer Fund.

Differentiation of F9 teratocarcinoma stem cells after transfer of c-*fos* proto-oncogenes

Rolf Müller & Erwin F. Wagner

European Molecular Biology Laboratory, Postfach 10.2209, 6900 Heidelberg, FRG

Transfer of mouse or human c-fos *proto-oncogenes into F9 teratocarcinoma stem cells results in expression of* c-fos *mRNA and protein. This is accompanied by the appearance of morphologically altered cells which express several specific markers characteristic of differentiated cells, suggesting that* c-fos *plays a role in cellular differentiation.*

RECENT analyses of the structure of retroviral oncogenes and of the expression of their cellular homologues (c-*onc* genes or proto-oncogenes) strongly support the hypothesis that the products encoded by such genes are directly linked with cellular growth control[1–6]. Amino acid sequence homologies suggest that the c-*sis* gene probably encodes the platelet-derived growth factor[1,2] and the c-*erb-B* gene product appears to be identical to the epidermal growth factor receptor[3]. Expression analyses have shown that the c-*myc* gene product may be associated with the initiation of normal cellular proliferation: high levels of c-*myc* transcripts were detected specifically during the early G_1 phase of the cell cycle when either quiescent lymphocytes[4] or fibroblasts[5] were stimulated to proliferate. In agreement with these conclusions, c-*myc* expression was seen to be down-regulated when teratocarcinoma stem cells (F9)[5] or immature haematopoietic cells (HL60)[6] were induced to differentiate into non-proliferative cell types. Terminal differentiation of HL60 cells was also accompanied by a decrease of c-*myb* expression[6].

Another category of c-*onc* genes appears to be represented by c-*fos* whose gene product may be associated with functions in differentiated cells[7–10]. Transcription of c-*fos* at high levels was detected during prenatal development in specific tissues, notably amnion and visceral yolk sac and mid-gestation fetal liver[7–10]. The level of c-*fos* expression in the fetal membranes increased markedly at late stages of gestation[8]. In postnatal tissues, expression of c-*fos* at high levels was observed only in haematopoietic cells[10]. In cells of the monomyelocytic lineage high levels of c-*fos* mRNA were detected specifically at late stages of differentiation[10].

We have started to introduce c-*fos* genes into a variety of different cell types and into fertilized mouse eggs in order to analyse a potential function of the c-*fos* gene product in differentiation processes. We describe here the results of a study using 'nullipotent' F9 teratocarcinoma stem cells[11] as recipients for the introduction of c-*fos* genes. Teratocarcinoma stem cells have been used as a model system to study differentiation and development[12], and the introduction of selectable and nonselectable genes into various established embryonal carcinoma cell lines has been accomplished[13]. F9 stem cells do not differentiate spontaneously in culture[11], but treatment with retinoic acid and dibutyryl cyclic AMP can lead to endoderm-like differentiation[14,15]. Depending on culture conditions, parietal or visceral endoderm-like cells are formed in the presence of the chemical inducers, as judged by the expression of several specific differentiation markers. It has also been shown that nerve growth factor can induce adrenergic neuronal differentiation in F9 cells treated with retinoic acid and dibutyryl cyclic AMP[16]. We show here that the expression of either the human or mouse c-*fos* gene following DNA-mediated gene transfer into F9 stem cells results in a drastic alteration of cell morphology and proliferative potential associated with the onset of expression of several differentiation markers.

Morphological alteration of F9 cells

In F9 stem cells, the level of c-*fos* expression is normally very low[17]. To analyse whether an increased expression of the c-*fos* gene product affects the differentiation state of these cells, either

Table 1 Quantitative evaluation of transfection experiments

DNA	Ratio c-*fos*: pSV2-neo (μg)	Total no. of colonies†	Fraction of morphologically altered colonies (%)
c-*fos* (human) + pSV2-neo	10:10	300	15
c-*fos* (human) + pSV2-neo	15:5	85	30
c-*fos* (human) + pSV2-neo	20:1	80	70
c-*fos* (mouse) + pSV2-neo	20:1	100	50
c-*fos* (human) digested with *Nco*I* + pSV2-neo	5:5	75	0
c-*fos* alone	10	0	0
pSV2-neo alone	5	75	0

* Cleaves within c-*fos* coding region.

† Values are from at least two independent experiments and are expressed per 10^6 transfected cells.

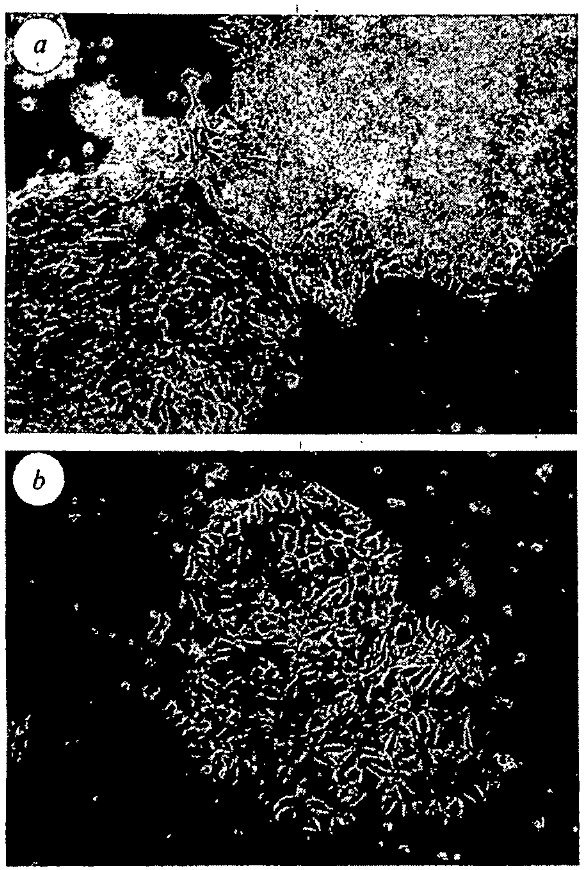

Fig. 1 Phase-contrast microscopy of F9 cells 10 days after co-transfection of c-*fos* and pSV2-neo and selection in G418-containing medium. *a*, The upper right colony is a typical F9 stem cell clone whereas in the lower left side, part of a characterisic c-*fos*-altered F9 clone is visible. *b*, A c-*fos*-altered F9 cell clone with the typical flat, epithelial-like morphology.

Method: DNA transfections were performed essentially as described[31,33,34]. The CaPO$_4$-precipitated DNA (20 μg human c-*fos* plasmid and 1 μg pSV2-neo) was added to 10^6 F9 cells and selection with G418 (1 mg ml^{-1}) was started 48 h later. Photographs were taken at magnification × 100.

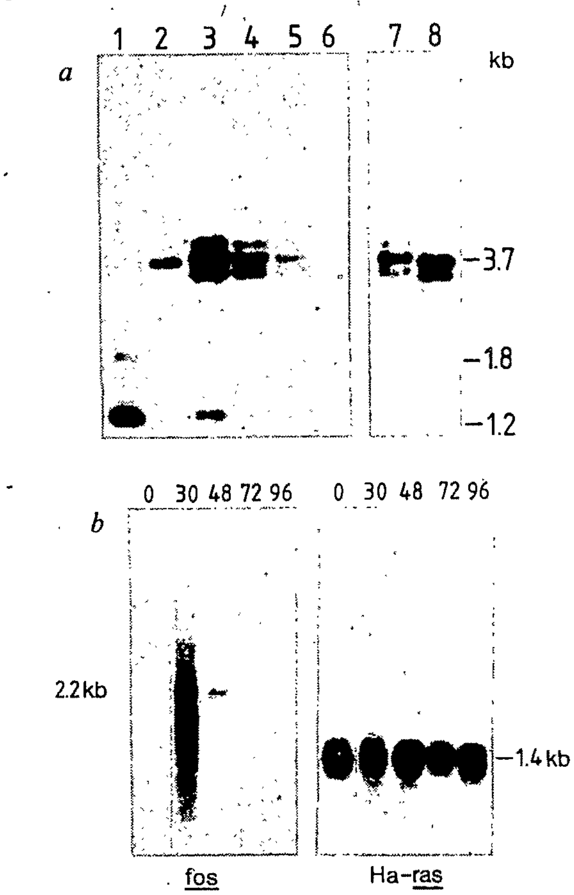

Fig. 2 *a*, Presence of exogenous c-*fos* DNA sequences in c-*fos*-altered F9 cells, 12 days after co-transfection of the human c-*fos* gene and pSV2-neo and subsequent selection in geneticin-containing medium. DNAs were digested with *Pvu*II and analysed by Southern blotting[21] using a v-*fos*-specific probe. Lane 1: normal F9 cells, 10 μg DNA; lane 2: normal human fibroblasts, 10 μg DNA; lanes 3–6: c-*fos*-altered F9 cells (experiment I, transfection of 10 μg c-*fos* and 10 μg pSV2-neo), 3 μg, 1 μg, 0.3 μg and 0.1 μg DNA (from left to right); lane 7, same as lane 3, but shorter exposure to facilitate comparison with lane 8 which contains c-*fos*-altered F9 cells (experiment II, transfection of 20 μg c-*fos* and 1 μg pSV2-neo). *b*, c-*fos* transcripts in transfected F9 stem cells. Poly(A)$^+$ RNA was isolated[35] 0, 30, 48, 72 and 96 h after transfecting 20 μg of the mouse c-*fos* plasmid[18] onto 10^6 F9 cells, separated on formaldehyde-containing agarose gels (8 μg per lane) and analysed by Northern blotting for transcripts hybridizing to a v-*fos* or v-Ha-*ras*-specific probe, respectively, as described[8,35,37]. The Ha-*ras*-specific probe was used to show that the pattern of expression observed with the *fos* probe was not due to quantitative or qualitative differences in the RNA samples analysed. After longer exposure of the same blot hybridized to the v-*fos*-specific probe, 2.2-kb transcripts were clearly visible at 96 h.

the human[18] or the mouse[19] c-*fos* gene and a plasmid (pSV2-neo)[20] containing a bacterial neomycin resistance gene were co-transfected into F9 stem cells. After selection in geneticin(G-418) containing medium for about 8–10 days, two types of colonies were detected with both c-*fos* genes: clones of cells showing the normal F9 stem cell morphology and colonies of greatly enlarged, flat cells growing in an epitheloid fashion (Fig. 1*a*, *b*). The maximum clone size of these morphologically altered cells was about 400 cells, although colonies consisting of less than 10 cells were also observed. No proliferative activity (as judged by clonal expansion) could be detected after 10–12 days in selective medium, whereas geneticin-resistant F9 stem cell clones continued to grow. The fraction of morphologically altered colonies was clearly dependent on the ratio of c-*fos*/pSV2-neo DNA used for transfection (Table 1). No clone of morphologically altered cells was obtained when the neomycin plasmid was transfected alone, or when the c-*fos* plasmid was cleaved within the coding region of c-*fos* prior to co-transfection (Table 1). No biological effect on F9 stem cells has been observed on transfer and expression of v-*myc* and v-*src*, which were linked to the metallothionein promoter region (M. Karin, personal communication). These results strongly suggested that the introduction of intact c-*fos* genes was responsible for the observed morphological alteration of F9 stem cells.

To obtain further evidence in support of this conclusion, DNA from transfected cultures was analysed for the presence of exogenous c-*fos* sequences (about 14 days after co-transfection of the normal human c-*fos* gene and the pSV2-neo plasmid). On digestion with *Pvu*II, the v-*fos*-specific probe used in this study recognized a fragment of 3.7 kilobases (kb) in human DNA and two fragments of 1.8 and 1.2 kb in mouse DNA (Fig. 2*a*). When mass cultures containing approximately 50% morphologically altered colonies were analysed by the Southern blot procedure[21], an average value of at least 20–50 copies per cell was determined for the exogenous human c-*fos* genes (Fig. 2*a*). When DNA from transfected, but morphologically normal, F9 cell clones was analysed by the same technique, only few intact copies of exogenous c-*fos* sequences were detected (R.M. and E.W., unpublished observation). These results suggest that c-*fos* expression in the morphologically altered F9 cells may result from low-level transcription of many exogeneous c-*fos* genes (see below).

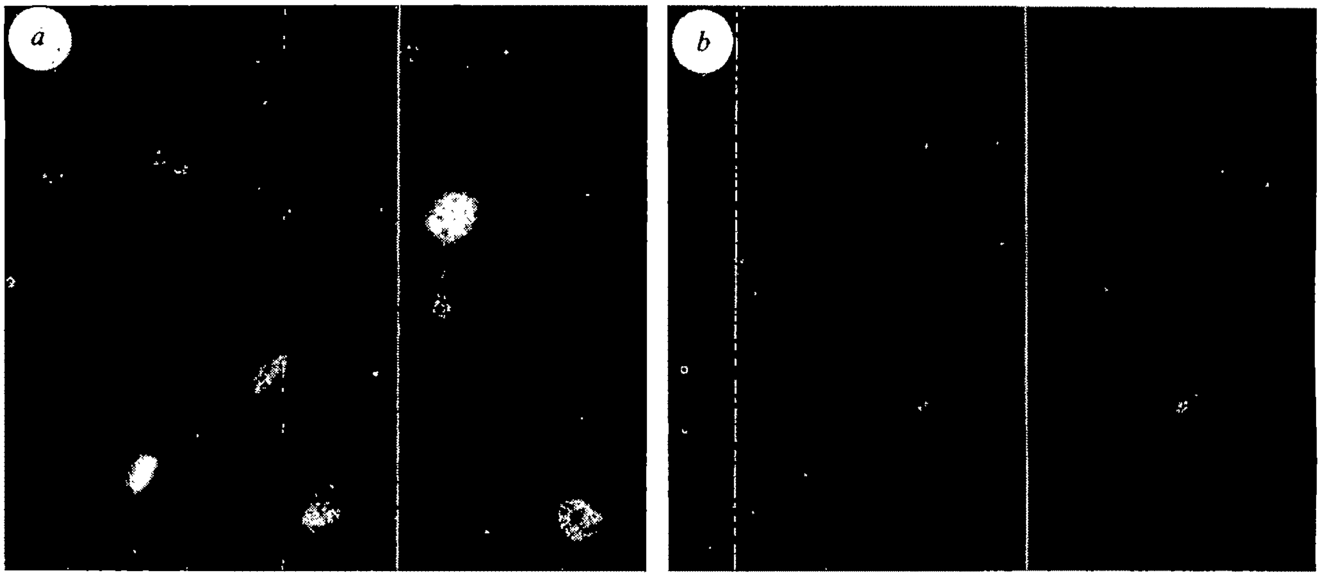

Fig. 3 Expression of c-*fos*-related nuclear protein in c-*fos*-altered F9 cells, 12 days after co-transfection of the human c-*fos* gene and pSV2-neo and subsequent selection in geneticin-containing medium. Double-antibody immunfluorescence using *fos*-specific TBRS[22,23] and a rhodamine isothiocyanate-conjugated sheep anti-rat-IgG antibody (provided by J. Adamkiewicz, University of Essen, FRG) was carried out on *p*-formaldehyde-fixed and Triton-permeabilized cells as described by Curran *et al.*[23]. *a*, *fos*-specific TBRS showing a clear nuclear staining[23]; *b*, preimmune serum showing only non-specific cytoplasmic fluorescence. Similarly, no specific nuclear staining was observed with TBR serum on normal F9 stem cells (not shown). Two different areas of the same culture are shown in both *a* and *b*.

Increased expression of c-*fos* mRNA

To examine whether the c-*fos*-induced morphological alteration was associated with elevated expression of c-*fos* mRNA, we analysed total poly(A)$^+$-containing RNA from cultures at different times after transfection of the mouse c-*fos* gene (thus including in the analysis all cells which had not taken up DNA). High levels of c-*fos*-related transcripts relative to untransfected F9 cells could be detected as early as 30 h after transfection (Fig. 2*b*). In addition to the normal c-*fos* mRNA of 2.2 kb, which has previously been described to be present in various mouse and human tissues[7–10], transcripts of heterogenous size producing a smear of c-*fos*-containing RNA were observed (Fig. 2*b*). At later times the level of c-*fos*-related RNA decreased and the c-*fos* transcripts predominantly occurred as normal 2.2-kb mRNA (Fig. 2*b*). These changes in the level and size of c-*fos* transcripts are apparently not due to variations in the RNA preparations, as neither quantitative nor qualitative changes could be observed when the same RNA blot was hybridized to a v-Ha-*ras*-specific probe (Fig. 2*b*). Our observations on c-*fos* expression might therefore reflect the elimination of extrachromosomal c-*fos* sequences or of unstable c-*fos* integration sites which could produce aberrant transcripts. The decrease of c-*fos* expression at later times could also occur because normal F9 stem cells may have a growth advantage over those cells which have taken up and express exogenous c-*fos* genes. Our results, however, demonstrate that c-*fos* sequences, on transfection into F9 stem cells, are transcribed at significant levels, leading to an over-expression of c-*fos* mRNA that is similar in size to the normal transcript.

Expression of c-*fos* protein

Exogenous c-*fos* genes transferred by transfection into F9 cells are transcriptionally active (Fig. 2*b*), but *Nco*I cleavage in the *fos* coding region abolishes this activity of the human c-*fos* gene (Table 1). These observations suggest that the altered F9 cell morphology may be induced by the c-*fos* protein. Using a tumour-bearing rat serum (TBRS), it has been reported recently that both v-*fos* and c-*fos* gene products are expressed as nuclear phosphoproteins in virus-transformed fibroblasts and in primary cultures of late-gestation mouse amnion cells, respectively[22,23]. This *fos*-specific antiserum was used here to investigate whether c-*fos* protein was expressed in the morphologically altered F9 cells. Because of the relatively low number of c-*fos*-altered F9 cells available, this analysis was only possible by using an *in situ* immunostaining procedure. As shown by immunofluorescence (Fig. 3), a strong nuclear staining was detected in most of the morphologically altered F9 cells. Only relatively weak nonspecific cytoplasmic staining (no nuclear fluorescence) was observed when either TBRS was used on normal F9 stem cells or when non-immune serum was applied to c-*fos*-altered F9 cells (Fig. 3). Therefore, our findings strongly suggest that c-*fos*

Table 2 Differentiation markers of c-*fos*-altered F9 cells compared with those of F9 stem cells, trophoblastic cells and endodermal cells

	Marker					
Cell type	TROMA-1[25,26]	TROMA-3[25,26]	Laminin[25,26]	AFP[26]	Fibronectin[25]	Deposited collagen type IV[26,27]
F9 stem cells	–	–	–	–	(+)	(–)
c-*fos*-transformed F9 cells	+	+	–	–	(+)	(+)*

Primitive endoderm	?	?	+	–	+	+
Parietal endoderm	+	(+)	+	–	–	+
Visceral endoderm	+	–	(+)	+	+	(+)

–, No expression detectable; (+), low level of expression; +, high level of expression (–, (+) and + correspond to –, +, more than one + in ref. 26).
* Variation among different clones from very low to high levels.

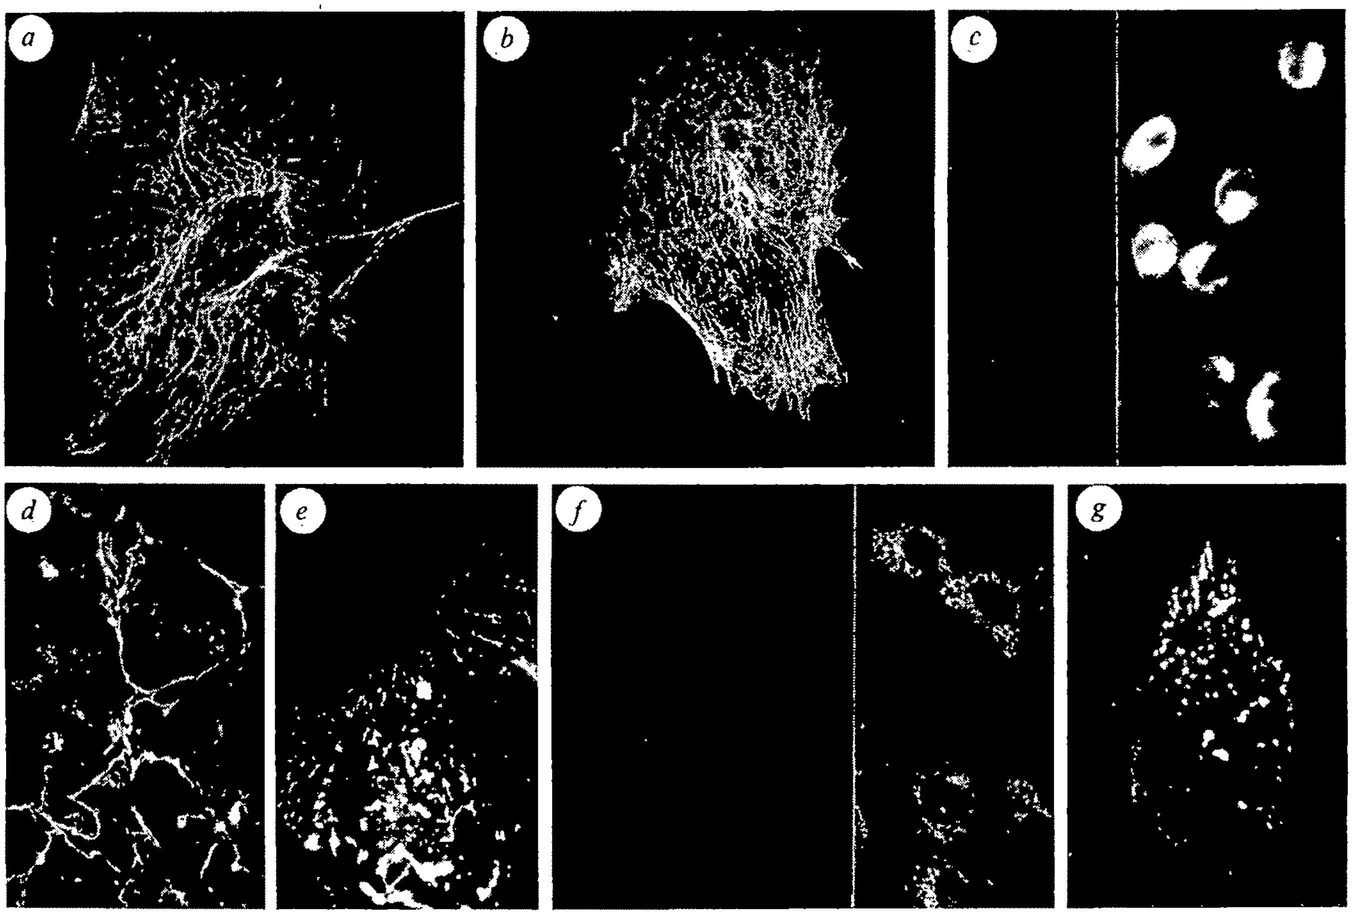

Fig. 4 Expression of differentiation markers in c-*fos*-altered F9 cells 12 days after co-transfection of the human c-*fos* gene and pSV2-neo and subsequent selection in geneticin-containing medium. Cells were fixed with Sante Marie reagent (ethanol/glacial acetic acid, 99:1 v/v) (*a–f*) or *p*-formaldehyde (*g*) and processed by double-antibody immunofluorescence as described elsewhere[38]. *a*, *b*: Mouse monoclonal antibodies TROMA-1 (*a*) and TROMA-3 (*b*) recognizing intermediate filaments[25] (provided by R. Kemler, Tübingen, FRG) on c-*fos*-altered F9 cells. *c*, Rabbit antiserum against AFP in c-*fos*-altered F9 cells (left) and in rat hepatoma cells (DTH2) as a positive control (right) (cells obtained from D. Paul, Hamburg, FRG; antiserum provided by E. Adamson, La Jolla, California). *d*, *e*: Rabbit antiserum against collagen type IV (given by K. von der Mark, Martinsried, FRG) on c-*fos*-altered F9 cells. *d*, Shows a clone of cells; *e* shows two single cells. *f*, Mouse monoclonal antibody against laminin (obtained from R. Kemler, Tübingen, FRG) on c-*fos*-altered F9 cells (left) and on the parietal endoderm-like teratocarcinoma cell line PYS-2 (as a positive control, right). *g*, Rabbit antiserum against hamster fibronectin (provided by H. Beug, EMBL; originally obtained from R. Hynes, MIT, Boston) on a c-*fos*-altered F9 cell. The second antibody was as in Fig. 3 (in *a*, *b*, *f*) or rhodamine isothiocyanate-conjugated sheep anti-rabbit IgG (Dakopatts, Hamburg, FRG) (*c*, *d*, *e*, *g*). Microscopic magnification ×400.

protein is synthesized in morphologically altered F9 cells. This observation is of particular relevance because other cell types may not efficiently express unmodified transfected c-*fos* genes[24]. Although these data do not yet prove a causative role for c-*fos* protein in the morphological alteration of F9 stem cells, such a function seems possible because c-*fos* mRNA was detected as early as 30 h after transfection. Thus, it seems that c-*fos* expression preceeds morphological alteration rather than vice versa.

Expression of differentiation markers

To investigate the nature of the morphologically altered F9 cells in further detail, we analysed the expression of a variety of differentiation markers in these cells. These studies were particularly designed to include those markers known to be switched on in F9 cells induced to differentiate by retinoic acid treatment[14,15,25–27]. The most dramatic change we observed was the appearance of an ordered intermediate filament network in the morphologically altered F9 cells (Fig. 4*a*, *b*). This network, which is entirely absent from normal F9 stem cells (data not shown; see ref. 25), was recognized by two monoclonal antibodies reacting with different intermediate filament components: TROMA-1 (Fig. 4*a*) and TROMA-3 (Fig. 4*b*). These antibodies have both been reported to bind to intermediate filament proteins, which are first detectable in tropho-ectodermal cells of the blastocyst[25]. While TROMA-1 antibodies also react strongly with both visceral and parietal endodermal cells, the specificity of TROMA-3 is more pronounced; this antibody shows a positive reaction (though weaker than TROMA-1) only on parietal endoderm (Table 2)[25,26]. In addition, both antibodies react with the primitive gut and fetal liver as well as with the mesoderm and endoderm-derived epithelia in adult animals. Although our results obtained with TROMA-1 and TROMA-3 already suggest the alteration by c-*fos* of F9 stem cells into an epithelioid cell type (in accord with the change in cell morphology; Fig. 1), the analysis of a larger number of differentiation markers was required to obtain a clearer picture of the cell type represented by the c-*fos*-altered F9 cells.

Figure 4*c*, *f* shows that the endodermal markers α-fetoprotein (AFP; expressed in visceral endoderm[26]) and laminin (expressed predominantly in parietal endoderm[26]) could not be detected in the morphologically altered F9 cells, although cell lines serving as positive controls showed strong reactions: the parietal endoderm-like cell line PYS-2[25] (Fig. 4*f*) and retinoic acid-induced F9 cells (data not shown) with monoclonal anti-laminin antibodies (Fig. 4*f*), and the rat hepatoma cell line DTH2 (D. Paul, personal communication) with anti-AFP serum (Fig. 4*c*).

Two other extracellular matrix proteins were found to be deposited in the morphologically altered F9 cells, fibronectin

(Fig. 4*g*) and collagen type IV (Fig. 4*d*, *e*)[26,27]. Fibronectin was detected as extracellular patches of protein (Fig. 4*g*) and as deposits on the plastic surface of the culture dish (not shown) at levels similar to that found in F9 stem cells. Collagen type IV was found in an intracellular form (Fig. 4*d*), in extracellular fibres within cell clones (Fig. 4*d*) and in patches on single cells (Fig. 4*e*). The pattern and level of collagen type IV expression was subject to some variation when different clones were compared.

Conclusions

Mouse and human c-*fos* genes are expressed in a stage-, tissue- and cell type specific fashion which has led to the hypothesis that products encoded by these c-*onc* genes may have a role in cellular differentiation processes[7–10]. One approach for testing this hypothesis is to transfer transcriptionally active genes into various undifferentiated cell types, in particular stem cells and fertilized eggs, and to analyse the biological effect of the exogenous gene products. In the present study we have shown that the introduction via transfection of c-*fos* genes into F9 teratocarcinoma cells gives rise to colonies of cells which are morphologically distinct from F9 stem cells, and which possess phenotypic properties characteristic of differentiated cells. The c-*fos*-altered F9 cells share several markers with trophoblastic and endodermal cells (in particular the intermediate filament proteins TROMA-1 and TROMA-3 as well as collagen type IV; Table 2)[25,26]. On the other hand, several markers diagnostic of retinoic acid-induced F9 cells and characteristic of either parietal endoderm (laminin)[25,26] or visceral endoderm (α-fetoprotein)[26] are not expressed in the c-*fos*-transfected, differentiated F9 cells. Thus, it seems that the differentiation pathways promoted by retinoic acid and c-*fos* are distinct events. Whether the c-*fos*-transfected F9 cells represent a normal cell type that has not yet been identified or whether an aberrant type of differentiation is triggered by c-*fos* is unknown. It is also possible that c-*fos* induces the expression of a particular set of genes, and that the acquisition of a terminal stage of differentiation requires the expression of another set of genes not controlled by c-*fos*. Nevertheless, our findings provide the first evidence that transfer of a single cellular gene can promote a cellular differentiation process, either by inducing differentiation in uncommitted stem cells or by conferring on committed cells present in the mass population of F9 cells the ability to pass through a predetermined differentiation pathway, for example by providing a maintenance function specifically required by differentiated cells.

Another intriguing aspect of this study is that c-*fos* sequences introduced into F9 stem cells were found to be expressed at both the mRNA and protein levels (Figs 2*b*, 3). Recently, it has been shown that c-*fos* genes transferred into fibroblastic cells are not efficiently expressed unless part of the 3′-untranslated region is removed from the transfected gene[24]. Such control mechanisms apparently do not exist in amniotic cells and, as shown here, also seem to be absent from c-*fos*-induced differentiated F9 cells. F9 stem cells could thus represent an invaluable tool for investigating the mechanims controlling c-*fos* mRNA and protein expression.

Our present observations, taken together with previous findings on c-*fos* expression in normal development, suggest a participation of the c-*fos* gene product in specific cellular differentiation processes. However, it should be emphasized that such a putative role of c-*fos* would not necessarily preclude its association with growth control mechanisms, a function suggested by the fact that the inappropriate expression of c-*fos* can lead to neoplastic transformation (uncontrolled cell proliferation)[24]. It is noteworthy that both differentiation-inducing properties and growth-promoting activities have been observed for nerve growth factor[16] and the v-*abl* gene product[28,29].

To elucidate the nature of the c-*fos*-altered F9 cells in greater detail, it is important to obtain larger numbers of these differentiated cells; this might be achieved by improving culture conditions (for example, to compensate for a possible requirement of the c-*fos*-altered cells for specific factors), by introducing 'immortalizing' genes[30,31] into the differentiated cells (to overcome a possible block of cell proliferation associated with terminal differentiation) or by using c-*fos*- gene constructs, allowing regulation of expression via inducible promoters[32] (in case the constitutive expression of high levels of c-*fos* expression is detrimental to the cell). To address these problems, we are currently introducing c-*fos* genes under the control of the metallothionein promoter[32] into various other stem cells and fertilized mouse eggs, either alone or together with the gene coding for the polyoma virus large-T antigen[30]. By using such inducible c-*fos* gene constructs, it may also be feasible to examine whether the promotion of differentiation by c-*fos* requires the selection of pre-existing committed cells in the mass population of F9 stem cells.

We thank E. Adamson, H. Beug, T. Curran, R. Kemler, K. von der Mark and R. Hynes for gifts of specific antibodies; T. Curran, R. Ellis, D. A. Miller and I. M. Verma for oncogene-specific probes and cloned c-*fos* genes; B. Adkins, K. von der Mark, H. Ponta and U. Rüther for valuable discussions and suggestions; M. Vanek for technical assistance and B. Blanasch for help in preparation of the manuscript.

Accretion disk limit cycle mechanism in twin-degenerate interacting binaries

J. K. Cannizzo

Department of Astronomy, University of Texas, Austin,
Texas 78712, USA

The twin-degenerate interacting binary stars are thought to consist of two pure helium white dwarfs in close orbit. The candidates are G61-29 (also GP Com), HZ 29 (also AM CVn) and, tentatively, PG1346+082[1]. Large variations in the optical light of PG1346+082 suggest variable accretion onto the star gaining mass. Such behaviour in the light curves of the classical dwarf novae is thought to be caused by either episodic mass overflow from the mass-losing star[2,3] or the instability in the accretion disk[4,5]. Here we investigate the latter mechanism, and explore the non-thermal equilibrium limit cycle behaviour of the accretion disk expected for a twin-degenerate interacting binary system.

G61-29 is a system containing two white dwarfs orbiting each other with a period of 46.5 min. Nather *et al.*[6] interpret this system as consisting of a low-mass white dwarf transferring matter to its more massive companion through the inner lagrangian point. They find that the hydrogen-to-helium ratio is at least a factor of 1,500 lower than its solar value. It is also generally accepted that HZ 29 consists of two white dwarfs in close proximity[7-9]. The rate of mass transfer is thought to be orders of magnitude higher than for G61-29 (refs 6, 8). If the mass-losing star is also a low-mass white dwarf in contact with its Roche lobe, the orbital period would be of the order of 1/2 h, given the size considerations for white dwarfs.

Smak[10] has pointed out that the disk limit cycle mechanism[11-17] hypothesized to account for the recurrent bursts seen in dwarf novae should also be applicable to twin-degenerate Hinteracting binaries. This instability mechanism results from changes in the vertical disk structure which occur when the midplane temperature is near the peak in the Rosseland opacity. For a density of $\rho = 10^{-7}$ g cm^{-3} this peak occurs at $T \approx 15{,}000$ K for solar composition material[18] and $T \approx 30{,}000$ K for pure helium material[19]. The effective temperature of the disk corresponding to the onset of instability is $T_{\rm eff} \approx 6{,}500$ K for the former[11-17] and $T_{\rm eff} \approx 9{,}000$ K for the latter[10]. A comparison of vertical structure computations[10,20] shows that in pure helium disks the instability occurs at a surface density which is a factor of 7.5 larger than that in disks composed of solar matter because of the higher temperatures.

The strongest evidence for dwarf nova-like nature of these objects is the resemblance of their spectra to those seen in the classical dwarf novae. The eruption spectra of dwarf novae show strong absorption lines and their light curves exhibit flickering. In HZ 29 one sees[8,9] He absorption lines and flickering. Also, emission features are seen in dwarf novae during the quiescent periods between the outbursts—just as one sees[6] emission lines of He in G61-29.

Preliminary observations of PG1346+082 appear to be at least consistent with the notion that it too contains two helium white dwarfs orbiting at close range (D. E. Winget, and R. E. Nather, personal communications). The average spectrum of PG1346+082 is devoid of hydrogen and strongly resembles that of HZ 29. As in HZ 29 the absorption features are shallower than those seen in lone white dwarf spectra. Observations of this object are preliminary and no light curves have been published. However, variations of 2–3 mag seen in the optical light from this system seem to hint at episodic disk flow onto the accreting star. Were this true, one would be faced with the prospect that $\dot{M}_{\rm T}$ does, in fact, lie in an 'unstable' range[10]. What would be the expected amplitudes, durations, and recurrence times for bursts produced in such a system?

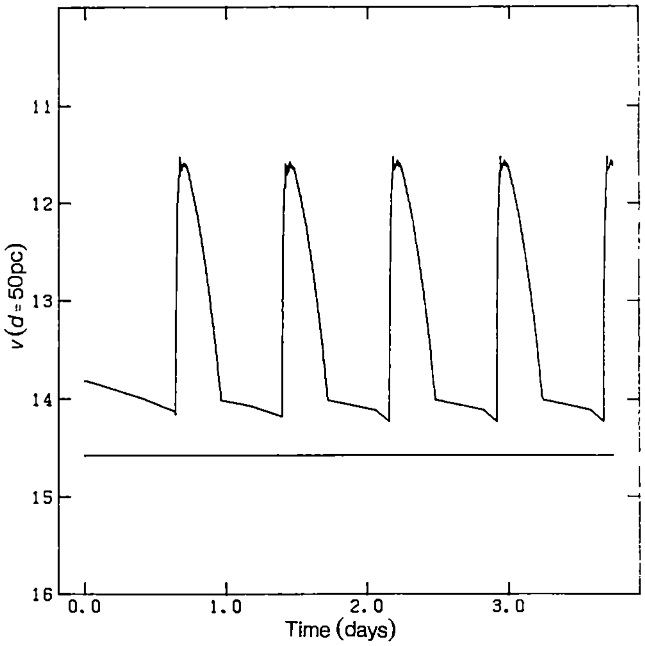

Fig. 1 A series of bursts for $\alpha_{\rm cold} = 0.05$, $\alpha_{\rm hot} = 0.2$, and $\dot{M}_{\rm T} = 5 \times 10^{-10}\ M_\odot\,{\rm yr}^{-1}$. The horizontal line represents the light from a typical white dwarf. The vertical axis is in units of apparent visual magnitude. The system quickly relaxes to a periodic behaviour with widely separated bursts occurring.

In an attempt to answer these questions we have employed a generalized time-dependent, non-thermal equilibrium accretion disk model developed for studying the classical dwarf novae. The mathematical formulation is similar to that being used elsewhere[20,21-24]. The exact method used[25] involves the α parameterization for the viscosity and consists of simultaneously solving for the temporal evolution of surface density and disk temperature.

Preliminary comparisons of theory with observation[25,26] using dwarf novae systems seem to demand $\alpha_{\rm cold} \approx 0.05$ and $\alpha_{\rm hot} \approx 0.2$. We take the inner disk edge to be at 5×10^8 cm, and the outer edge at 4×10^9 cm. Mass is added to the disk at a constant rate at 2.5×10^9 cm—an appropriate injection radius for $P = 1/2$ h. A radial grid of 40 points is used. At the inner edge we set $\Sigma = 0$, and at the outer edge we set $v_{\rm r} = 0$ (where $v_{\rm r}$ is the radial flow speed). We assume a face-on disk in computing the light curves presented below.

We use the opacities of Heubner *et al.*[19] which characterize matter with the composition $X = 0$, $Z = 0.001$ (where X is the hydrogen mass fraction and Z is the metal mass fraction). Power law scalings for the critical surface densities associated with the limit cycle are taken from computations using solar composition material[16]. These surface densities have to be multiplied by 7.5 for the helium-rich matter considered here.

We have computed a series of bursts for a wide range of values of the secondary mass transfer rate $\dot{M}_{\rm T}$. Figures 1 and 2 show a series of bursts for representative low and high values of $\dot{M}_{\rm T}$. The horizontal line represents the luminosity of a white dwarf with effective temperature, $T_{\rm eff} = 30{,}000$ K and radius $r_{\rm wd} = 5 \times 10^8$ cm. The varying curve gives the disk contribution. We take the distance to be $d = 50$ pc. In quiescence the optical depth through the disk vertically is $\tau \approx 1$ at all radii, and the disk temperature is $T \approx 10{,}000$ K. In outburst, the disk effective temperature varies between about 20,000 K and 50,000 K. The optical flux from the disk rises about two magnitudes in going from quiescence to outburst.

Even for very low $\dot{M}_{\rm T}$ we still find bursts occurring. For $\dot{M}_{\rm T} = 2 \times 10^{-11}\ M_\odot\,{\rm yr}^{-1}$ (corresponding to G61-29) the bursts

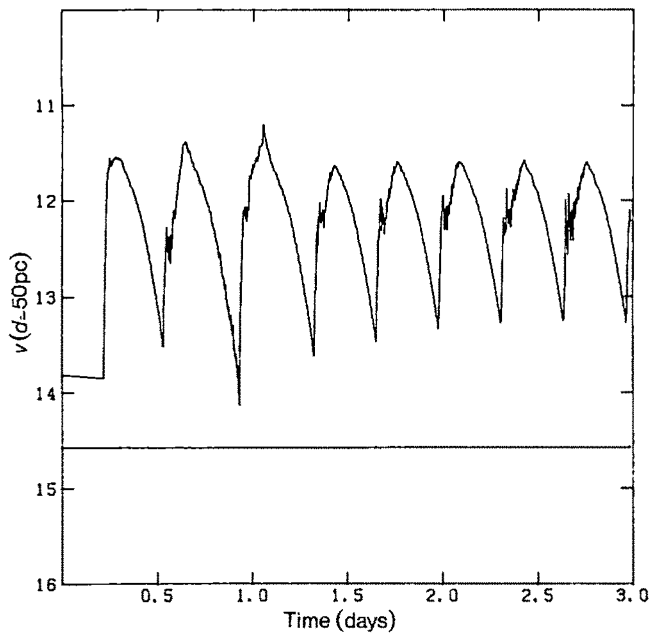

Fig. 2 A series of bursts for $\dot{M}_T = 1.5\times10^{-9}\,M_\odot\,\mathrm{yr}^{-1}$. Other parameters are as in Fig. 1. After three bursts the system settles to a repetitive pattern with closely spaced bursts.

happen once every 10 days and last about 5 h. Hence for the parameters chosen we predict a duty cycle of about 2%. So far this system has only been seen in the 'low' state. As $\dot{M}_T$ is increased the interval between bursts decreases but the duration of the burst itself increases slightly. The bursts shown in Fig. 1 for which $\dot{M}_T = 5\times10^{-10}\,M_\odot\,\mathrm{yr}^{-1}$ occur about once every 16 hours. There is still a sizeable quiescent period. Figure 2 depicts the system behaviour for $\dot{M}_T = 1.5\times10^{-9}\,M_\odot\,\mathrm{yr}^{-1}$. The bursts now occur so rapidly that the inner part of the disk is still in the high state when the next burst is initiated at larger radii. For even higher $\dot{M}_T$ the inner disk is always in the high state. Only the outer disk alternates between the low and high states. The disk light oscillates within a few tenths of a magnitude of $m_v = 12$. For $\dot{M}_T$ corresponding to HZ 29 the entire disk is in steady-state.

The burst amplitudes to be expected in a helium twin-degenerate interacting binary system are about three magnitudes, or less if $\dot{M}_T$ is large. The time between bursts is hard to predict from a theoretical standpoint without knowing $\dot{M}_T$. Indeed, a knowledge of the recurrence time should place limits on $\dot{M}_T$. If bursts are seen in one of these systems, the disk apparent magnitudes presented here should enable one to infer a distance, given an assumption for the disk inclination.

I thank Don Winget, Ed Nather, Rick Hessman, and Matt Wood for bringing PG 1346 + 082 to my attention and for discussing the existing observations of this object. I also thank Don Winget for making available the Heubner *et al.*[19] opacities, Doug Lin and Greg Shields for discussions involving the nonthermal equilibrium model, and especially Craig Wheeler for useful discussions of accretion disk physics and critical reading of this manuscript. This research was supported in part by NASA grant NSG 7232.

Boltzmann's ultraviolet cutoff and Nekhoroshev's theorem on Arnold diffusion

Giancarlo Benettin*, Luigi Galgani† & Antonio Giorgilli‡

The greatest difficulty with classical statistical mechanics may be the fact that some degrees of freedom do not seem to attain the energy expected from the equipartition principle. This is typical of the vibrational modes in molecules and of the high frequencies in the electromagnetic radiation (problem of the ultraviolet cutoff). Boltzmann[1] had the intuition that an explanation might be provided if each degree of freedom were to have a characteristic relaxation time until equilibrium, and that such a time should greatly increase with frequency; he spoke in terms of relaxation times of days or centuries. This possibility was seriously considered by Rayleigh and Jeans[2], but they could not produce a clear classical mechanism to explain the freezing of the high frequency degrees of freedom; so, the equilibrium concept of the ultraviolet cutoff provided by quantum mechanics was accepted, and Boltzmann's hypothesis was forgotten. Here we point out that a general framework for understanding the ultraviolet cutoff in Boltzmann's dynamical sense in a classical context seems to be provided by Nekhoroshev's[3] theorem on Arnold diffusion.

The Komogorov–Arnold–Moser (KAM) theorem[4–9] on the existence of invariant tori in nearly integrable Hamiltonian systems was stated in 1954, the same year in which Fermi *et al.*[10] found that a classical nonlinear string did not relax to equilibrium within the time then available to the computer. In the KAM theorem one concentrates on results which are valid for infinite times, and this imposes a strong limitation to the set of initial data, which are restricted to the complement of a dense open set. This is a serious obstacle to a physical interpretation. In Nekhoroshev's theorem, however, where the evolution of the system is considered only for finite (but large) times, one obtains estimates which are valid in open sets of phase space, and not only on the invariant tori.

Nekhoroshev considers an analytical Hamiltonian $H(I, \phi) = H^0(I) + \varepsilon H^1(I, \phi)$ for a system with s degrees of freedom, where $I = (I_1, \dots, I_s)$ and $\phi = (\phi_1, \dots, \phi_s)$ are action-angle variables, H^1 is 2π-periodic in $\phi_1, \dots, \phi_s$, $\varepsilon \ll 1$ is a perturbative parameter, and H^0 satisfies certain 'steepness conditions' (for example, H^0 is convex). Then his main theorem continues:

Let $0 < \varepsilon < \varepsilon^0$. Then for every solution $I(t)$, $\phi(t)$ of the system with Hamiltonian $H^0 + \varepsilon H^1$ one has

$$|I(t) - I(0)| < \mathscr{I}\varepsilon^b \qquad (1)$$

for all $t \in (0, T)$, where

$$T = \tau \frac{1}{\varepsilon} \exp\left(\frac{1}{\varepsilon}\right)^a \qquad (2)$$

with suitable positive constants a, b depending on H^0, $\mathscr{I}$ and τ being natural units, of action and time respectively, entering the problem.

Here $|\cdots|$ is the Euclidean norm in R^s. The actions are thus 'frozen' up to very long times, which increase exponentially with decreasing ε, if the perturbation is small enough. The dimensional constants $\mathscr{I}$ and τ are widely arbitrary, and, as often used in the mathematical literature, they were set equal to unity in Nekhoroshev's paper.

But what interests us here is his extrapolation to systems of coupled harmonic oscillators. In such cases, one considers a Hamiltonian of the form

$$H(p, q) = \sum_{j=1}^{s} \tfrac{1}{2}\omega_j(p_j^2 + q_j^2) + \sum_{k \geq 3} H^{(k)}(q)$$

where $p = (p_1, \ldots, p_s) \in R^s$ and $q = (q_1, \ldots, q_s) \in R^s$ are cartesian coordinates around an elliptic equilibrium point, the constants $\omega_1, \ldots, \omega_s$ being the harmonic frequencies and $H^{(k)}$ a polynomial of order k in the variables q; no small parameter ε is needed in the Hamiltonian, and the smallness is measured in terms of the Euclidean distance from the fixed point. As the quadratic part of the Hamiltonian does not satisfy the steepness conditions required in Nekhoroshev's theorem, one adapts the Hamiltonian by a preliminary change of variables which is the same used to apply KAM theorem[8]. Specifically, we assume that among the harmonic frequencies $\omega_1, \ldots, \omega_s$ there are now low-order resonances, that is, a positive integer l exists such that no relations of the form $\sum_{j=1}^{s} k_j\omega_j = 0$ are satisfied, $k_1, \ldots, k_s$ being integers with $0 < |k_1| + \cdots + |k_s| \leq l$. Then, through a sequence of $l-2$ Birkhoff's transformations, and using the new variables I, ϕ, where $I_j = \frac{1}{2}(p_j^2 + q_j^2) + \cdots$, theHamiltonian takes the form $H'(I, \phi) = H^0(I) + H^1(I, \phi)$, where H^0 is in general, steep and H^1 starts with terms of order $|I|^{l/2}$. One has to take into account the fact that any Birkhoff's transformation produces a restriction of the domain around the fixed point where the new Hamiltonian is defined; thus, for any given set of harmonic frequencies, one could, in principle, find an optimal l. In any case, the new Hamiltonian H' can be defined for small enough actions, say for $|I| < A$, with a given 'critical action' A. Then one can apply the theorem quoted above, and still obtain the estimates in equations (1) and (2), the only difference being that ε has to be replaced by a quantity ε_{eff} depending on the initial data and defined by

$$\varepsilon_{\text{eff}} = \left(\frac{|I(0)|}{A}\right)^{l/2}$$

This is given in Nekhoroshev's paper with A set equal to unity.

Such a mathematical result seems strongly to indicate that the high frequency degrees of freedom are frozen. Indeed, let us consider a very special initial condition, such that only one oscillator, say the jth one, is excited, that is, one has $I_i(0) = 0$ for $i \neq j$. In terms of the harmonic energies E_j of the oscillators with harmonic frequencies ω_j, because of the relation $E_j = \omega_j I_j$ which holds in a first approximation, one has then

$$\varepsilon_{\text{eff}} \simeq \left(\frac{|E_j(0)|}{A\omega_j}\right)^{l/2},$$

and the theorem guarantees that such oscillator is 'frozen', that is, it has small fluctuations of energy, up to a time T_j which, as seen from equation (2), is exponentially increasing with frequency. In this sense, the theorem seems to provide a general mechanism for freezing of the higher frequencies, as advocated by Boltzmann. In addition, this actually occurs for energies below some critical energies proportional to frequency. The latter posssibility was indeed conjectured more than 10 yr ago, on the basis of an analogy of critical energy with quantum zero-point energy, taking into account the adiabatic invariance of the action[11–12].

There are several limitations to these considerations. First, the class of initial conditions to which Nekhoroshev's theorem directly applies is not broad enough, because one also ought to consider initial conditions with some oscillators below, and others above, the respective thresholds. Furthermore, in the KAM theory, and thus also in Nekhoroshev's theorem, there are extremely small lower estimates for the thresholds, even for situations with few degrees of freedom as, for example, in molecules. This difficulty is enhanced for most systems of interest in statistical mechanics, which involve many degrees of freedom, because such lower estimates tend rapidly towards zero as the number of degrees of freedom tends to infinity (in the thermodynamic limit). In this connection, we note that the available lower estimates in KAM theory are highly non-optimal; in addition, it seems that the estimates of the thermodynamic limit would be improved if they were restricted to special classes of physically-relevant perturbations, such as those corresponding to short-range interactions (low connectance, in the terminology of refs 13, 14); in particular, this should be the case for systems of particles coupled by typical molecular potentials, such as the Lennard–Jones potential. This is supported by some results we have obtained using classical perturbation theory, which appear to agree with the indications given, since several years, by numerical computations[15–23].

Thus, we conclude that the most general theorem available in classical perturbation theory, strongly supports the intuition of Boltzmann of almost a century ago, and deserves serious consideration. In any case, the relevance of metaequilibrium states has been often pointed out. This is illustrated by the physics of spin temperatures, where the system considered, that of nuclear spins, appears to have temperatures quite different from the temperature of the supporting system, that is the lattice, and from the temperature of the surrounding radiation field, just because "the internal thermal equilibrium time of the elements of the system is short compared to the time during which appreciable energy is lost or gained from other systems"[24]. In such cases, for example, the first time is of the order of 10^{-5} s, while the relaxation time to the lattice is often of the order of many minutes or even days. Analogous situations are also met in connection with the rotational and the vibrational degrees of freedom of molecules, where a different temperature is often reported for any degree of freedom[25].

For a discussion of other problems related to the questions mentioned above, see refs 26–29.

Note added in proof: A first result proving the applicability of Nekhoroshev's theorem in the thermodynamic limit for short-range interactions, at least in a special case, has been independently obtained by C. E. Wayne[30].

Maximum entropy signal processing in practical NMR spectroscopy

Sibusiso Sibisi*, John Skilling*, Richard G. Brereton†, Ernest D. Laue† & James Staunton†

* Department of Applied Mathematics and Theoretical Physics,
Silver Street, Cambridge CB3 9EW, UK

Cambridge CB2 1EW, UK

NMR spectroscopy is intrinsically insensitive, a frequently serious limitation especially in biochemical applications where sample size is limited and compounds may be too insoluble or unstable for data to be accumulated over long periods. Fourier transform (FT) NMR was developed by Ernst[1] to speed up the accumulation of useful data, dramatically improving the quality of spectra obtained in a given observing time by recording the free induction decay (FID) data directly in time, at the cost of requiring numerical processing. Ernst also proposed that more information could be obtained from the spectrum if the FID was multiplied by a suitable apodizing function before being Fourier transformed. For example (see ref. 2), an increase in sensitivity can result from the use of a matched filter[1], whereas an increase in resolution can be achieved by the use of gaussian multiplication[1,3], application of sine bells[4–8] or convolution difference[9]. These methods are now used routinely in NMR data processing. The maximum entropy method (MEM)[10] is theoretically capable of achieving simultaneous enhancement in both respects[11], and this has been borne out in practice in other fields where it has been applied. However, this technique requires relatively heavy computation. We describe here the first practical application of MEM to NMR, and we analyse ^{13}C and ^{1}H NMR spectra of 2-vinyl pyridine. Compared with conventional spectra, MEM gives considerable suppression of noise, accompanied by significant resolution enhancement. Multiplets in the ^{1}H spectra are resolved better leading to improved visual clarity.

For a given FID, many spectra can be produced which are consistent with the data—too many for easy comprehension. Nevertheless, we must, in practice, select just a single spectrum. It has been shown[12,13] that MEM is the only generally consistent selection procedure. We maximize the entropy (negative information content)

$$S = -\int f(\nu)\log f(\nu)\,\mathrm{d}\nu \quad (f \text{ normalized to } \textstyle\int f\,\mathrm{d}\nu = 1)$$

of the spectrum $f(\nu)$ of oscillator number densities, and in this way can select the spectrum which has the minimum of structure and hence fewest artefacts. Note that the '$f \log f$' formula used here differs from the '$\int \log f(\nu)\,\mathrm{d}\nu$' entropy form commonly used[14–16] in maximum entropy time-series analysis. The latter form produces a spectrum which gives greatest flexibility (maximum entropy) to individual samples from a time-series constrained by autocorrelation data. In NMR by contrast, we observe the FID time-series directly, and we are interested in the spectrum $f(\nu)$ as an object in its own right. For both these reasons, we should use the $f \log f$ form[17]. NMR data analysis is akin to radio interferometry[18,19], where $f \log f$ is also appropriate, but NMR has the advantage of being free of peripheral arguments such as that about the role of the statistics of radio photons[20].

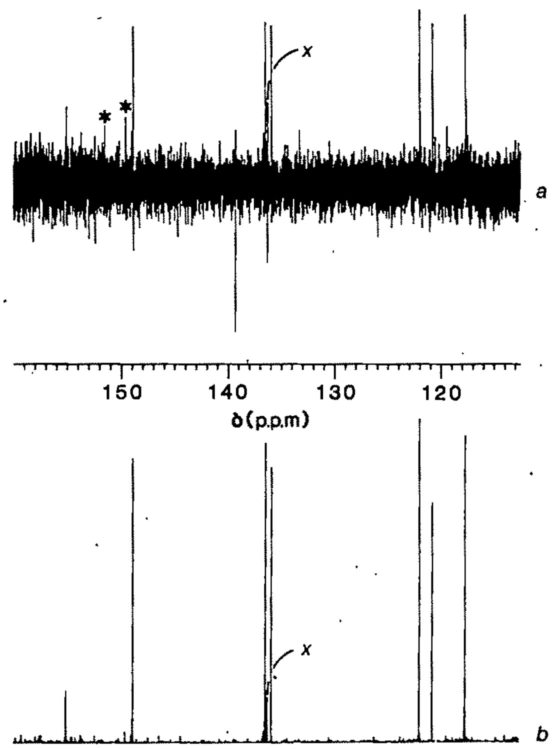

Fig. 1 *a*, Conventional Fourier transform of the ^{13}C FID produced by a pulse of 1.6 μs on a sample of 2-vinyl pyridine in CDCl$_3$. *b*, MEM spectrum from the same FID. ×, Instrumental artefact, attributed to imperfect transmitter gating.

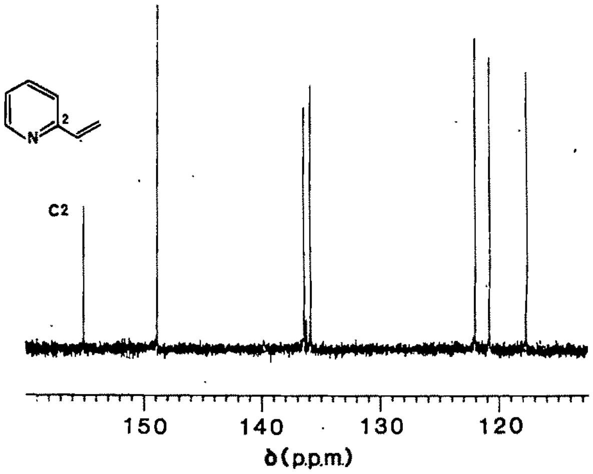

Fig. 2 Conventional Fourier transform of the ^{13}C FID produced by a pulse of 13 μs.

Note that MEM produces a spectrum which has to fit the data, in the sense that the distribution of oscillators would produce a FID not significantly different from the actual data. Conventional methods of processing, such as direct or apodized Fourier transforms, give spectra which lack this property.

The ^{13}C data for 2-vinyl pyridine in CDCl$_3$ were recorded on a Bruker WM-250 instrument using the manufacturer's quadrature phase cycling and quadrature detection mode. We present results for a noisy test spectrum determined using a short pulse

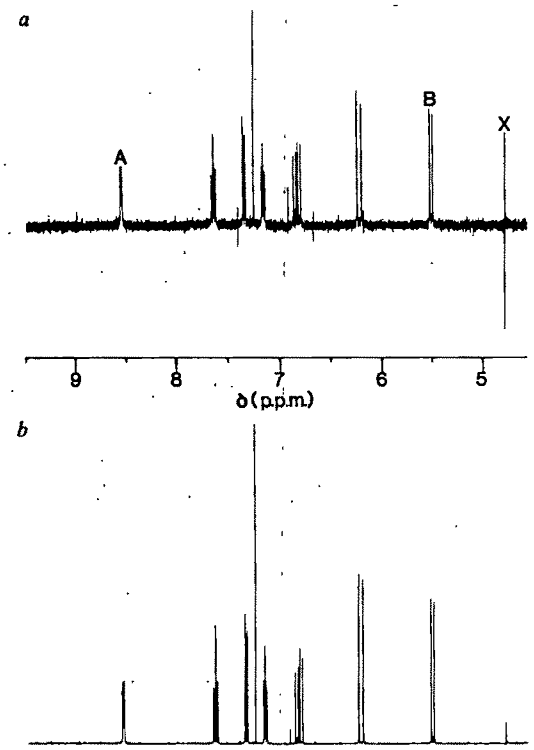

Fig. 3 *a*, ¹H spectrum of 2-vinyl pyridine produced by conventional Fourier transform. *b*, Corresponding MEM spectrum.

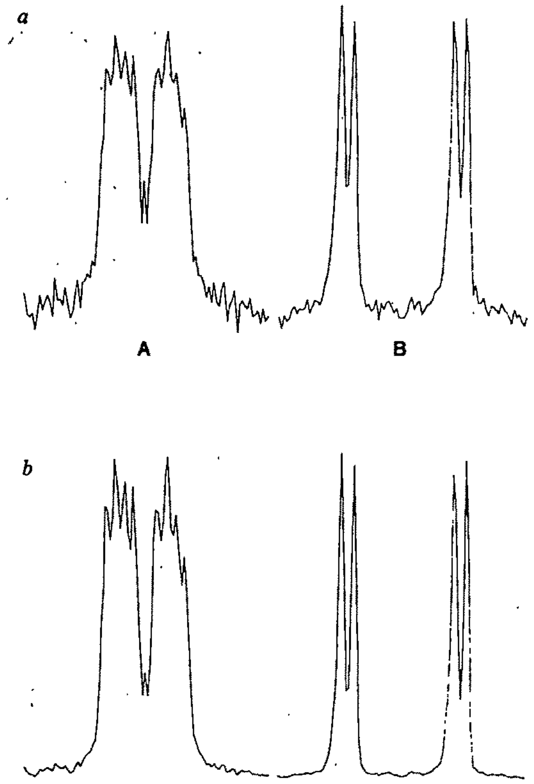

Fig. 4 *a*, Expansions of the multiplets A and B in the conventional spectrum (Fig. 3*a*). *b*, Expansions of the multiplets A and B in the MEM spectrum (Fig. 3*b*).

time (1.6 μs). We corrected the baseline of the FID and converted it from quadrature to cosine form[21] over 8,192 points before zero filling to 16,384 points. The Cambridge MEM algorithm[22] was used to find the two principal phase parameters, by maximizing the entropy over both the spectrum and these parameters simultaneously. The phase parameters were then used for both the conventional FT and MEM spectra shown in Fig. 1.

In the conventional FT spectrum, Fig. 1*a*, the signals assigned to C-3, C-4, C-5, C-6, C-7 and C-8 are reasonably clear of the noise, but the signal from C-2 is only marginally higher than some of the noise peaks (marked with asterisks). In the corresponding MEM spectrum obtained from the same data (Fig. 1*b*), noise is dramatically decreased, so that the peak for C-2 appears much more convincing. The reliability of the lines shown in the MEM spectrum can be assessed by comparison with a control FT spectrum (Fig. 2) produced from the same sample, using a longer pulse time (13 μs) to increase the signal-to-noise ratio. This proves that the C-2 line picked out by maximum entropy is a true signal, as opposed to the noise peaks marked with asterisks in Fig. 1*a*. The ability of MEM to discriminate in favour of real signals, and against noise of similar intensity, was reproduced in three other test spectra determined in the same conditions.

The ¹H data were recorded in a similar manner on a Bruker WH-400 instrument. We selected a moderately noisy spectrum to give a clear comparison between MEM and conventional procedures. Figure 3*a* shows the conventional Fourier spectrum, and Fig. 3*b* the corresponding MEM spectrum. In addition to the obvious suppression of noise, MEM has also sharply reduced the instrumental artefact, X. Two representative multiplets, A and B, are plotted on expanded scales in Fig. 4*a* (conventional) and Fig. 4*b* (MEM). The multiplets are appreciably sharper and better resolved in the MEM spectrum. Although not dramatic, this effect shows that suppression of noise is by no means accompanied by a loss of resolution, so that the technique should be of value in processing spectra that are crowded as well as noisy.

These results demonstrate that MEM provides a potentially important addition to the range of techniques currently available for producing NMR spectra. Details of the Cambridge MEM algorithm used to produce these spectra will be published elsewhere[22]. The disadvantage of MEM is the extra computing involved, amounting to about 1 min on a IBM3081 mainframe computer. The algorithm requires eight times the store and about 30 times the central processing time of an ordinary Fourier transform. Further work is in progress on the application of MEM to ¹H and ²H NMR spectra, and also on the more sophisticated approach in which a two-dimensional map is reconstructed from one-dimensional data[11].

We thank the SERC and St John's College, Cambridge, for financial support, and Drs J. D. Mersh and J. K. M. Sanders for use of their data transfer software. We also thank Dr Sanders for helpful comments.

High $^3He/^4He$ ratio in ocean sediments

M. Ozima, M. Takayanagi, S. Zashu & S. Amari

Geophysical Institute, University of Tokyo, Tokyo 113, Japan

Two decades ago, Merrihue[1] reported $^3He/^4He$ ratios of $>10^{-4}$ in ferromagnetic separates from a Pacific deep ocean red clay and concluded that the high ratio is due to extraterrestrial debris amounting to ~1% of the sediment. A decade later Krylov *et al.*[2] compiled $^3He/^4He$ isotopic data on ocean sediments measured in the Soviet Union and observed that the $^3He/^4He$ ratio is generally higher in pelagic sediments where the sedimentation rate is lower. They suggested that the high $^3He/^4He$ ratio was attributable to extraterrestrial materials which were concentrated in slowly accumulating ocean floor. However, these important discoveries were almost completely neglected until we re-examined the problem. We have measured 39 sediments from 12 different sites, 10 sites from the western to central Pacific and two sites from the Atlantic Ocean. We find $^3He/^4He$ ratios $>5\times10^{-5}$ for six sites, well above the values generally observed in common terrestrial materials. The very high $^3He/^4He$ ratio in the sediments is probably due to input of extraterrestrial materials. Input of stratospheric dust of $\lesssim1$ p.p.m., which corresponds to a fallout rate of ~2,000 tons per year, can explain the observation.

All the sediments that we studied are piston-cored samples. While two Atlantic sediments (DSDP samples) are of Cretaceous age[3,4], all the Pacific samples are of Quaternary or, at most, of late Tertiary age[5,6]. Petrographical descriptions and other data of the samples are given either in a DSDP Initial Report[3,4] or in the Preliminary Report for the *Hakuho Maru* cruise[5,6]. All the Pacific and Atlantic samples are very fine-grained typical pelagic sediment. A few hundred milligrams of a sample were hand-picked from a sediment core (diameter, 5 cm), which had been stored with a thick plastic cover (Pacific samples). Sediments were almost completely dried out and consolidated. Before gas extraction, samples were heated in vacuum at ~150 °C to reduce surface air contamination. No further treatment of the samples, such as cleaning was attempted.

The detailed experimental procedures for the gas extraction and the mass spectrometric analysis are described elsewhere[7]. Helium isotopic measurements were done with a resolution of 600 and ^3He peak was completely resolved from HD and H_3. The measured $^3He/^4He$ isotopic ratio was calibrated against an air helium isotopic ratio, which was measured repeatedly during the sample runs. The mass spectrometer has a dual collector for simultaneous measurements of ^3He and ^4He. Neither the mass spectrometer nor the extraction system have been used previously to analyse extraterrestrial materials. With these precautions, we believe that the measured helium isotopic ratios are satisfactorily free from interference or contamination effects, or from mass discrimination.

Table 1 shows the experimental data. The principle uncertainty in the experimental results comes from the correction for the hot blank. We assigned 50% of the hot blank as a possible error, in addition to the analytical error in the mass spectrometry, the latter being generally much less than the former. Because the variation in the hot blank throughout the experimental period was <10%, a possible error of 50% of the hot blank would be an overestimation. Except for Ar, there was too little of the other noble gases to allow reliable quantitative or isotopic analyses. In most cases the $^{40}Ar/^{36}Ar$ ratio is significantly higher than the atmospheric ratio, that is 295.5.

Measurements made on samples taken from the same level in a core (~1 cm apart in the same level) (KH75-3-5-2: levels 100 and 860 cm) show considerable difference both in the He content and in the isotopic ratio. The above consideration of the error estimation suggests that this difference is primarily due to sample heterogeneity owing to the small size (~100 mg) used for the experiment.

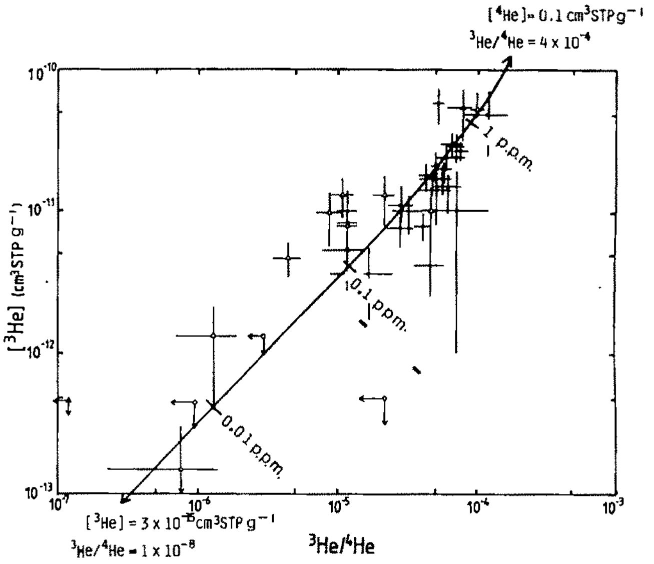

Fig. 1 ^3He content in sediments is plotted against $^3He/^4He$ ratio. The curve indicates the mixing between He in the cosmic dust ($^4He = 0.1\ cm^3STP\ g^{-1}$, $^3He/^4He = 4\times10^{-4}$) and in the sediments ($^3He = 3\times10^{-15}\ cm^3STP\ g^{-1}$, $^3He/^4He = 10^{-8}$). Numbers on the curve indicate the degree of the contamination (in p.p.m.) of the cosmic dust in sediments. △, KH-80-3; ○, KH68-4; ●, KH75-3-5; □, KH-75-3-11; ◇, DSDP.

Although the few data available make it difficult to draw a general conclusion on the distribution of $^3He/^4He$ ratios in ocean sediments, there appears to be no clear correlation between isotopic ratio and geography. However, it should be noted that high $^3He/^4He$ value ($>5\times10^{-5}$) is common in the Pacific sediments. Except for diamonds[8], the highest $^3He/^4He$ ratio ever reported for terrestrial materials is 5.2×10^{-5} for Hawaiian olivine xenoliths[9], the values for common terrestrial rocks such as granites being $\ll5\times10^{-5}$ (ref. 10). ^3He production in the Earth is practically negligible[11]. It is also difficult to attribute the high $^3He/^4He$ ratio to some artificial nuclear fallout or debris, as samples were taken at more than two different levels in a core considerably deeper than the seabed and in several cases the deeper level showed the higher $^3He/^4He$ ratio. Because extraterrestrial materials have $^3He/^4He$ ratios generally higher than 10^{-4} with high helium content ($^4He \geq 10^{-5}\ cm^3STP\ g^{-1}$)[10], it is reasonable to assume input of some extraterrestrial materials to the sediments to account for their high $^3He/^4He$ ratios ($>5\times10^{-5}$). This assumption is supported by the following observation.

Figure 1 shows the $^3He/^4He$ ratio plotted against ^3He content. There appears to be a clear positive correlation between them which can be explained by the mixing of some materials with a high ^3He content and $^3He/^4He$ ratios with sediment which has a generally low He content[12]. We can imagine either meteorite fragments or cosmic dust as possible contaminants. If meteorite fragments were produced by meteoritic impact on the Earth, the occurrence of high $^3He/^4He$ in ocean sediment must be sporadic. The observation of a common high $^3He/^4He$ ratio in ocean sediments, not only in the lateral but also in the vertical sections, contradicts the sporadic meteorite impact theory. Also, an impact would result in severe helium loss from the meteorite debris. Hence, we favour the cosmic dust origin for the anomalously-high $^3He/^4He$ ratio in the sediments.

If global fallout of cosmic dust were responsible for the high $^3He/^4He$ ratio as well as to the high ^3He content, we would expect an inverse relationship between the concentration of the cosmic dust and the sedimentation rate, because in the high accumulating region, the fallout cosmic dust must be diluted by terrestrial materials. Figure 2 shows the ^3He content plotted against the sedimentation rate (taken from refs 3–6). Two Atlan-

* About 100 mg of sample was handpicked from a sediment core at the designated interval (depth from the water bottom for the Pacific samples and depth at respective core section for the Atlantic samples).

† ^{3}He/^{4}He ratio is calibrated against air helium ^{3}He/^{4}He ratio to reduce a mass fractionation effect.

‡ Errors in ^{3}He and ^{4}He consist of 50% of the hot blank and 1σ in the mass spectrometry, the former being much larger than the latter.

§ A fraction of the extracted gas was introduced into a mass spectrometer. Hence, only the isotopic ratio was measured and the helium amounts were not measured (NM).

tic samples are quite isolated from Pacific samples. This may be due to helium-loss from the Atlantic samples, because they are older by a factor of 100 than the Pacific sediments. Ignoring the Atlantic samples, there still seems to be an approximately inverse relation between the ^{3}He content and the sedimentation rate. If we assume uniform fallout rate of cosmic dust and also that the initial ^{3}He content in sediment is negligible, then the ^{3}He concentration in the sediment, which can be taken as a measure of the amount of cosmic dust input, can be expressed as a function of sedimentation rate (r) and flux of the cosmic dust fallout (f),

$$(^3\mathrm{He})_{\mathrm{sed}} = \frac{\alpha f}{\rho r} \qquad (1)$$

where α and ρ denote respectively the concentration of ^{3}He in the extraterrestrial material and density of the sediment. For the

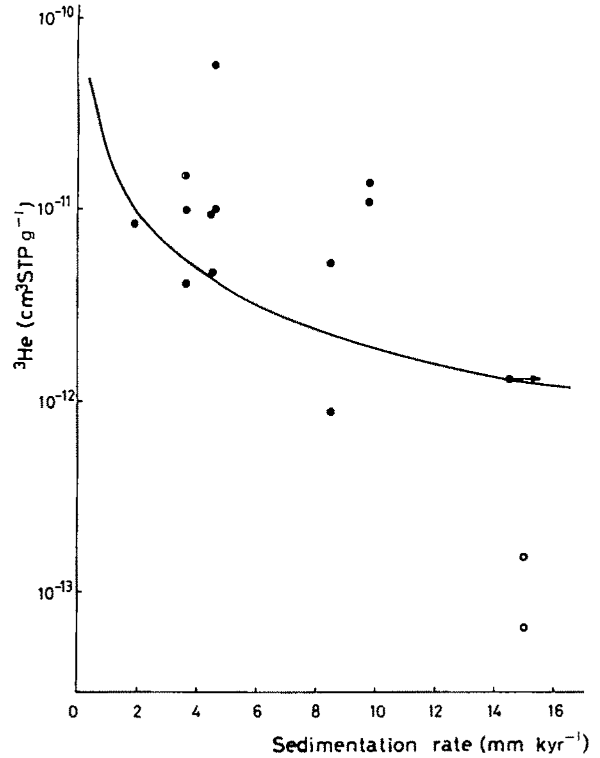

Fig. 2 ^{3}He content plotted against sedimentation rate. ○, The Atlantic DSDP samples which are of Cretaceous age. The Pacific samples (●) show an approximately inverse relationship between ^{3}He content and sedimentation rate. The curve is constructed by assuming uniform fallout rate (2,000 tons yr^{-1}) of cosmic dust ($^4\text{He} = 0.1$ cm^{3}STP g^{-1}, $^3\text{He}/^4\text{He} = 4\times10^{-4}$).

^{3}He concentration in the cosmic dust, we take the value measured for stratospheric cosmic dust (~10-μm diameter size), that is $\alpha = 4\times10^{-5}$ cm^{3}STP g^{-1}. Putting $\alpha = 4\times10^{-5}$ cm^{3}STP g^{-1} and $\rho = 2$ g cm^{-3} in equation (1), we can construct a family of curves corresponding to different values of f. Figure 2 shows a curve corresponding to $f = 4\times10^{-10}$ g cm^{-2} yr^{-1}, which approximates the data. The value $f(=4\times10^{-10}$ g cm^{-2} y$^{-1})$ corresponds to a cosmic dust fallout rate of about 2,000 tons yr^{-1}. The value may be favourably compared with the estimate made on satellite, radio and visual observations of about a few hundred tons per year for particle size below 10 μm in diameter[13], considering the large uncertainty in the estimates of the fallout rate and the helium content of the cosmic dusts. Cosmic dust which has a diameter greater than 10 μm may not be important in the helium inventory of sediments, because the larger grains are likely to lose helium due to atmospheric impact heating[14]. Because various factors such as the non-uniform fallout rate of the cosmic dust, heterogeneity in their ^{3}He content and He-loss from the cosmic dust particles all act to disturb the simple inverse relation between ^{3}He content and sedimentation rate, it is quite normal to observe only an approximate inverse relation if the cosmic dust fallout is indeed responsible for the high $^3\text{He}/^4\text{He}$ ratio. Hence, we believe that it is the approximate inverse relationship and not the random relationship between the ^{3}He content and sedimentation rate which is significant and that this relationship is attributable to the global cosmic dust fallout.

Assuming that the cosmic dust is responsible for the high $^3\text{He}/^4\text{He}$ ratio, Fig. 1 also shows a mixing curve between the cosmic dust and the sediment. For the cosmic dust, we take $^4\text{He} = 0.1$ cm^{3}STP g^{-1} (ref. 14) and assume solar-wind implanted helium, that is, $^3\text{He}/^4\text{He} = 4\times10^{-4}$. For the uncontaminated sediments, we assumed a typical crustal value of 10^{-8} for $^3\text{He}/^4\text{He}$ ratio[11] and $^4\text{He} = 3\times10^{-7}$ cm^{3}STP g^{-1} (ref. 12). The choice of the values for the sediments is not crucial. In fact, changing the value by a factor of 100 does not significantly alter the mixing curve. Figure 1 shows that <1 p.p.m. input of the cosmic dust can account for the observed high $^3\text{He}/^4\text{He}$ as well as the high ^{3}He content. A preliminary study to search for extraterrestrial materials was made on sample KH75-3-5-2. Microscopic examination did not show any such evidence. Neutron activation analyses showed slightly higher Ni (200–600 p.p.m.) and Co contents (100–200 p.p.m.), but Cr (30–50 p.p.m.) is slightly lower than that observed in common crustal rocks. We could not detect Ir. Note that because of the very significant difference in He isotopic ratios of extraterrestrial and terrestrial materials, the method is potentially very useful for identifying input of the former to ocean sediments.

In the case of sample KH75-3-5-2 (total core length ≈9 m), there seems to be a progressive increase both in the ^{3}He content and $^3\text{He}/^4\text{He}$ ratio with increasing depth. This may be due either to the change in the cosmic dust fallout rate, or to that in the sedimentation rate, or to the both.

We thank Professor K. Kobayashi and Dr T. Furuta for Pacific sediments and helpful comments.

Occurrence of subtidal dolomite in a hypersaline lagoon, Kuwait

A. Gunatilaka, A. Saleh, A. Al-Temeemi & N. Nassar

Department of Geology, Kuwait University, Box 5969, Kuwait

We report here the discovery of subtidal dolomite in a shallow hypersaline lagoon during a study of Recent carbonate and evaporite sediments in the Al-Khiran region of southern Kuwait in the northern part of the Arabian Gulf (Fig. 1). Diagenetic dolomites are known from a variety of geographical locations and a spectrum of environmental conditions[1–6]. Although many occurrences of subaqueous dolomite have been documented[1–4], none has been reported from the subtidal areas of extensive Recent marine carbonate environments. The Al-Khiran dolomites show complex polyhedral crystal habits and a composition which ranges from $Ca_{51}Mg_{49}$ to $Ca_{56}Mg_{44}$. We postulate that a partial removal of dissolved sulphate ions (by bacterial reduction) from the interstitial waters of the sediments, the moderate Mg^{2+}/Ca^{2+} ratios of the hypersaline waters and the occasional near-schizohaline conditions in the lagoon may be responsible for the formation of this dolomite.

The small Al-Khiran lagoon is the remnant of a much larger body of water which is now partly infilled and dry (Fig. 1), and is connected to the Arabian Gulf by a small tidal channel. The maximum spring tidal range is ~2.2 m and the lagoon drains out almost completely only two or three times each year. Most of the time there is at least 0.50 m of water in the lagoon, and its floor is colonized by a sparse cover of *Halodule* plants. Lagoon salinities are fairly uniform throughout most of the year (42–44‰) and occasionally rise to 50–52‰ in the hottest months (July–August). The average summer and winter air temperatures

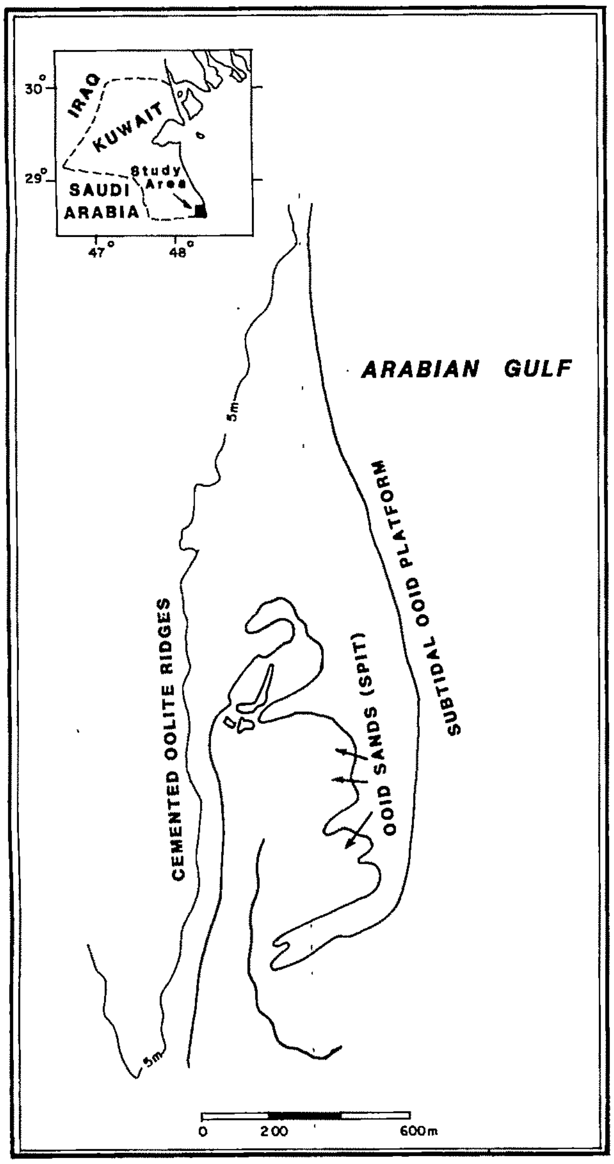

Fig. 1 The Al-Khiran lagoon and location of the study area.

are 45-47 °C and 12-15 °C, respectively. Water temperatures may exceed 30 °C in the summer and fall to as low as 8 °C in the winter months. Rainfall averages 100-120 mm yr^{-1}, but ranges up to 300 mm yr^{-1}.

The lagoon sediments are mostly a mixture of pellet muds and biodegraded skeletal material with some ooids (5–8%) and average ~70% aragonite. A representative lithological section (from cores) is shown in Fig. 2. The entire sediment column to a depth of more than 100 cm is highly reducing and organic-rich. Many samples from the lagoon bottom were analysed by X-ray diffraction and all contained diagenetic dolomite; it is most common in the upper 5 cm of the cores but occasionally is found at depths of 8–10 cm. The average dolomite content is 3.6% by weight of the total carbonate fraction and ranges from 3.2 to 4% (as determined by recalculation from 12 chemical analyses; the margin of error is too high when determining low dolomite contents by X-ray methods). The molar composition of dolomite was determined by measuring the peak shift of the (104) dolomite reflection relative to the (101) quartz reflection (internal standard)[7]; the standard error of the mean is ±0.20 mol% $CaCO_3$ in dolomite for seven replicates. Dolomite composition averages $Ca_{51.8}Mg_{48.2}$ (range is Ca_{51} to Ca_{56}, based on 22 analyses). The dolomites are all Ca-rich and poorly ordered and have diffraction characteristics typical of naturally occurring early diagenetic 'dolomites'[7,8].

Scanning electron microscope (SEM) examination of several of these samples reveals that the dolomite crystals are well developed with complex polyhedral crystal habits, and range in size from <1 μm to ~5 μm (Fig. 3). They are found most commonly as clusters within minute 'solution' cavities on the surfaces of pellets and, less frequently, within the aragonitic needle mud fraction. Surprisingly, the development of the unit rhomb alone is very rare. The most common crystal form is the unit rhomb bevelled by a pair of triangular-shaped basal pinacoids (0001; 000$\bar{1}$) which may be equally or subequally (asymmetrically) developed in a given crystal (Fig. 3). Less commonly, various other vicinal facets develop, modifying the rhombic symmetry. Although X-ray analysis does not indicate the presence of any gypsum, the scanning electron micrographs do show trace quantities of microcrystalline, euhedral gypsum crystals in the sediment.

The concentrations of Mg and Ca in lagoon surface and squeezed interstitial waters were determined by standard atomic absorption methods and sulphate concentration was measured by a turbidimetric method[9]. Carbonate alkalinity was determined by acid titration. All analyses were performed with reference to standard seawater to ensure good precision and accuracy. The results are summarized in Table 1.

The data indicate moderate Mg/Ca ratios, but more important from the point of view of dolomite formation is the reduced levels of dissolved sulphate in the pore fluids compared with surface waters; this is due to the high degree of microbial sulphate reduction within the sediments which prevents large-scale build-up of SO_4^{2-} concentrations. The alkalinity of the reduced pore waters is slightly higher than that of surface waters, but we do not consider this significant, particularly because there was a lapse of ~30 h between collection and analysis (most critical for alkalinity).

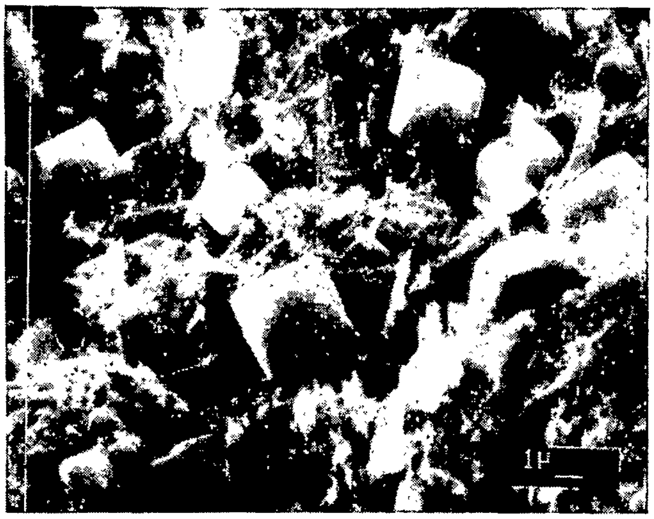

Fig. 3 Scanning electron micrograph of subtidal dolomite crystals from the Al-Khiran lagoon. The sample is from 7 cm depth in the core. Note the polyhedral crystal habits and particularly the unit rhomb modified by basal pinacoids.

In the winter months of 1982–83, ~240 mm of rainfall were recorded in the area, with one thunderstorm accounting for 128 mm in 18 h. The latter episode diluted and flushed the lagoon waters temporarily, but significantly, bringing it down to ~16‰ salinity (and possibly much lower as salinity was measured the day after the thunderstorm subsided) and producing mild schizohaline conditions. Freshwater flushing of hypersaline environments can be an important process in dolomite formation[10]. Freshwater flushing, however, does not markedly reduce the Mg/Ca ratio of the lagoon waters from its normal hypersaline values; if this were the case, the reduction of sulphate ion levels in the sediments (through microbial activity and/or by producing schizohaline conditions) could be more important than high Mg/Ca ratios or high salinities for dolomite formation[11]. Baker and Kastner suggest[11] that high concentrations of SO_4^{2-} ions suppress efficient dolomite nucleation in subtidal or open marine environments, and may be one of the kinetic barriers preventing large-scale dolomite precipitation from seawater, despite the fact that it is the thermodynamically preferred carbonate phase.

Based on the vast amount of data already available, it seems that high Mg/Ca ratios and salinities of pore waters should generate dolomites that are near stoichiometric in composition, and as the Mg/Ca ratio and salinities decrease the dolomites should depart from ideal stoichiometry[6]. The Al-Khiran data seem to agree with this general premise. However, other factors may be involved in determining stoichiometric behaviour[6].

The presence of dolomite in the top few centimetres of the sediments indicates that it formed in the very recent past of the lagoon and with the advent of quiet water conditions (pellet muds). The ooid sands below the dolomite represent the open and high-energy conditions of a shoal environment. Furthermore, the presence of patchy subtidal hardgrounds would act as a barrier for flushing and downward movement of potentially dolomitizing fluids. This difference between the nature of the lagoon now compared with earlier times shows the importance of the environment in dolomite genesis.

Dolomitization is a very complex process and opinion is divided as to the mechanisms involved in formation of diagenetic dolomites[2,3,4,6,10,11]. What is the mechanism operating during Recent dolomite genesis in an environment of reduced sulphate concentration and moderate Mg/Ca ratios, with the possible influence of occasional schizohaline conditions in the lagoon? Mass balance calculations indicate that with Mg/Ca ratios of 5.2–6.3 and average porosities in similar sediments, more dolomite should form than is observed in Al-Khiran. Massive dolomitization, however, (even in sabkhas) depends on more complex hydrodynamic behaviour of pore fluids in a sediment column (Al-Khiran sabkhas show Mg/Ca values of 10–14, yet the dolomite levels are rarely above 8%). Hence, the Mg/Ca ratio argument appears to be a geochemically weak one. However, moderate Mg/Ca values may be essential to stabilize the dolomite once it is formed[4]. Thus, the low SO_4^{2-} ion concentrations in the pore fluids are the most likely controlling factor in dolomite genesis. In fact, the effects of sulphate reduction on carbonate alkalinity are regarded by some authors as a critical factor for carbonate precipitation[4,11]. We do not imply that the dolomite is a direct precipitate from lagoon waters; rather, the textural evidence from scanning electron microscopy demonstrates that it may be a replacive, cement phase, having formed at the expense of micritic aragonite (Fig. 3).

Table 1 Carbonate alkalinity and levels of SO_4^{2-}, Ca and Mg in lagoon surface and interstitial waters

	Surface waters	Reduced pore waters
SO_4^{2-} concentration (M)	0.030–0.036 (0.034)	0.020–0.028 (0.025)
Carbonate alkalinity (M)	0.0033–0.0034 (0.0033)	0.0036–0.0041 (0.0037)
Mg^{2+}/Ca^{2+} ratio (molar)	5.2–6.3	5.4–6.2

Values are the range (mean).

It is instructive to compare Al-Khiran with other geochemically similar environments of Recent dolomite formation. Subtidal dolomite has not been reported from the Trucial Coast lagoons of the southern Arabian Gulf[12,13], where schizohaline conditions are probably never achieved (only 30–40 mm rainfall yr^{-1}). In contrast, Al-Khiran experiences slight drops in salinity every year during the wet season and mild schizohaline conditions at least once every few years, particularly during neap-tidal phases when the volume of water in the lagoon is considerably reduced. In the extremely evaporitic and stratified Solar Lake[4], dolomite formation is seasonal and the driving mechanism is the very efficient seepage-reflux of Mg-rich hot brines, which also explains why it forms at depth and not at the surface of the sediments. The dolomite here too is a replacement following aragonite. The occurrence of dolomite in Naxos[3] represents an example of dolomitization in much milder environmental conditions. These two cases and Al-Khiran have one common geochemical feature, that is, the reduction in sulphate ion levels of the potentially dolomitizing fluids, with a dramatic increase in carbonate alkalinity in the case of the Solar Lake[4]. Thus, a combination of water dynamics and fluid compositions could account for these occurrences.

An important implication of this study is that in a prograding coastline, there could be two generations of dolomite in the sediments, having formed either during the subtidal lagoonal phase and/or during the later supratidal sabkha phase by flood-recharge and refluxing, and it may not be possible to distinguish between them. We hope that such dolomite occurrences will encourage carbonate geologists to reinterpret at least some of the literature on dolomite.

We thank Dr D. Shearman for valuable suggestions. This research was made possible by a grant from the Kuwait University Research Council.

Cobalt in pore waters of marine sediments

David Heggie & Tim Lewis

Graduate School of Oceanography, University of Rhode Island, Kingston, Rhode Island 02881, USA

During early diagenesis on the sea floor, metal-recycling processes exert important controls on the preservation rates and distributions of metals in marine sediments. The elucidation of internal recycling processes, therefore, is important in understanding trace-metal mass balances in the oceans. Recent measurements of cobalt in seawater[1] suggest that cobalt is scavenged from the deep sea and hence follows biogeochemical pathways similar to manganese. We present here measurements of cobalt in pore waters of marine sediments and find that cobalt was released into pore waters in the sub-oxic sediment zone during dissolution of sedimentary manganese oxides (Table 1, Fig. 1). Solid-phase cobalt concentrations in surface (oxic) sediments, above the pore water remobilization horizon, are almost double those measured in the deep (anoxic) sediment zone (Table 2, Fig. 1). The sediment and pore water distributions indicate that a large fraction of sedimentary cobalt is recycled with manganese between oxic and sub-oxic pore waters and redeposited in surface (oxic) sediments.

Pore water samples were obtained from the Hatteras Abyssal Plain and Continental Rise sites of the western Atlantic and from the San Clemente Basin off southern California (Table 1). Sediments from gravity and box cores were loaded into polyethylene tubes and pore waters separated by centrifuging at 13,000 r.p.m. for 5 min (20,800*g*). Pore waters were filtered through precleaned 0.4-μm polycarbonate filters and acidified to *p*H ~ 2 in precleaned polyethylene vials. Cobalt was determined by direct-injection atomic absorption spectrometry on a Perkin Elmer 5000 with Zeeman background correction capability[2]. The detection limit for 60 μl injections was ~2.5 nmol kg^{-1} and precision is ±10% at concentrations of 10–50 nmol kg^{-1}. The technique is not sensitive enough to detect the cobalt levels measured in seawater[1].

The concentrations of cobalt, manganese, nitrate and ammonia in pore waters are listed in Table 1. We use nitrate and ammonia data to infer the 'redox' character of the sediments[3]. The depth of the nitrate maximum indicates the approximate depth of penetration of bottom water oxygen into the sediments[4] and, therefore, oxic sediments. Nitrate depletions below the maximum measured, and the appearance of

HAP, Hatteras Abyssal Plain; HCR, Hatteras Continental Rise; SCB, San Clemente Basin. Reported Co and Mn Atlantic bottom water (BW) concentrations do not reflect 'true' bottom waters. However, we emphasize that we are not able to distinguish differences between bottom waters and surface sediment (oxic) pore water concentrations. Co and Mn were measured in Atlantic Bottom waters (H. Windom, personal communication) at 20 pmol kg^{-1} and <1 nmol kg^{-1} respectively at depths of 3,800–5,600 m. We have measured the reported Mn content from San Clemente Basin of 10 nmol kg^{-1} on several cruises to this area. Co has been measured[1] at 27 pmol kg^{-1} in coastal Pacific waters at 1,900 m depth.

Table 2 Sediment concentrations

Depth (cm)	Total Mn	Leach Mn	Total Co	Leach Co
	(mmol kg^{-1} dry sediment)		(μmol kg^{-1} dry sediment)	
1	49.4	36.0	376.5	130.2
3	67.8	52.7	379.4	133.3
5	62.2	47.3	375.8	165.7
7	22.7	11.2	308.4	86.1
9	12.1	3.2	242.9	53.5
11	14.4	4.8	321.2	78.9
13	13.8	3.7	280.3	77.4
16.5	12.1	3.2	254.7	70.0
26.5	12.1	2.7	261.5	66.5
31.5	11.2	2.6	196.1	61.6

All data are corrected for % $CaCO_3$. A USGS rock standard GSP-1 and an in house Pacific pelagic sediment standard A3A were analysed along with BC-4 samples. Reported[20] Co and Mn concentrations for GSP-1 are 6 p.p.m. and 0.04 wt % Mn, respectively, compared with our analyses of 6.5 ± 1.0 p.p.m. Co and 0.03 wt % Mn. Similarly, reported concentrations of standard A3A (A. Graybeal, personal communication) are 66 ± 6 p.p.m. Co and 6.6 ± 0.1 wt % Mn, while our data are 58 ± 5 p.p.m. Co and 6.7 ± 0.1 wt % Mn.

Table 3 Comparisons of pore water cobalt and manganese fluxes with surface sediment excess metal accumulation rates, Hatteras Continental Rise, core BC-4

Core and metal HCR BC-4	Excess metal accumulation rate: Pore water flux (nmol cm^{-2} yr^{-1})	'Total'	'Leach'
		(nmol cm^{-2} yr^{-1})	
Mn	160	113	109
Co	0.5	0.3	0.2

Pore water flux $= \phi D_s\, dc/dz$. The 'average' concentration gradient (dc/dz) between oxic and sub-oxic sediments has been estimated between depths 5–13 cm and 5–11 cm for Mn and Co respectively. ϕ is porosity (0.7) and D_s is the bulk sediment diffusion coefficient[21] (D_s for Mn and Co are 57 and 63 cm^2 yr^{-1} respectively) obtained from the ionic diffusion coefficient[22] corrected to *in situ* temperatures (2°C) and further corrected for porosity and a formation resistivity factor[21] of 2.5. We estimate a 50% uncertainty in the pore water flux calculations. 'Excess' metal accumulation rate $= \Delta C \times D \times S$. ΔC is the concentration difference between mean surface oxic zone (<7 cm) metal concentrations and asymptotic concentrations in anoxic zone sediments for both 'total' and 'leach' metal digestions and extracts respectively. The *in situ* dry bulk density (D) was estimated[23] at 0.32 and the sedimentation rate estimated from the down-core $CaCO_3$ profile[24], from core GC-5, at 10 cm kyr^{-1}.

manganese in the pore waters, indicate the sub-oxic zone of sediments[3]. Rapidly rising ammonia, produced during sulphate reduction[3,5], indicates anoxic sediments.

We find that pore water cobalt concentrations are undetectable (<2.5 nmol kg^{-1}) in oxic zone sediments of Hatteras Abyssal Plain cores PC-11 and SC-3 (Table 1). However, cobalt concentrations rise rapidly from these concentrations in the oxic zone to maximum concentrations of 25–50 nmol kg^{-1} in the manganese reduction zone of Hatteras Continental Rise sediments BC-4 and GC-5. Pore water cobalt and manganese are shown for one core, BC-4, in Fig. 1. Similarly, in the San Clemente Basin pore water cobalt rises to 15 nmol kg^{-1} in the manganese reduction zone. Cobalt has been found adsorbed onto the surfaces of manganese oxide phases[6–8] and oxidized there to Co(III) (refs 9, 10). The data presented here indicate that cobalt is released to pore waters during reductive dissolution of manganese oxides. The shape of the cobalt profile indicates that cobalt in pore waters is diffused towards the sediment–seawater interface and is removed from pore waters to surface oxic sediments. The maximum cobalt concentration appears at shallower depths than the maximum manganese concentration, an unexpected result if cobalt and manganese undergo congruent dissolution. While we cannot explain this observation, cobalt in pore waters may diffuse further than manganese towards surface oxic sediments before it is removed to the solid phase. Cobalt concentrations decrease below the observed maximum in the sub-oxic sediment zone to near undetectable levels measured in anoxic sediments at depths <100 cm in Hatteras Continental Rise cores BC-4 (Fig. 1), and GC-5 (Table 1). Decreasing cobalt concentrations probably result from the precipitation of insoluble cobalt sulphides[11], formed during sulphate reduction which begins at shallow depths (~10 cm) in Hatteras Continental Rise cores.

Sediment samples for 'total' metal analyses were digested in an aqua-regia–hydrofluoric acid mixture[12,13]. Extracts of weakly bound or leachable metals were prepared by shaking sediment samples in ammonium oxalate–oxalic acid[14] mixtures. 'Total' metal digestions and 'leach' extracts were analysed for cobalt and manganese by flameless and flame atomic absorption spectrometry respectively. The analytical precision of 'total' and 'leach' cobalt analyses was respectively ±12% and ±5% over the concentration ranges reported here. 'Total' and 'leach' cobalt and manganese from the Hatteras Continental Rise core BC-4 are also shown in Fig. 1 and summarized in Table 2. Cobalt concentrations are highest in the top <7 cm of sediments and decrease sharply to near asymptotic concentrations at depths near 11 cm. Cobalt enrichments in the core tops are similar to the sediment manganese distributions (Fig. 1). However, while the top/bottom enrichment of sedimentary 'leach' manganese is near 10-fold, that of cobalt is only near two-fold. The processes of manganese release to sub-oxic pore waters and reprecipitation in surface oxic sediments, resulting in an enriched zone in oxic sediments, have been well documented[3,15–18]. The data presented here show that cobalt is recycled during dissolution and reprecipitation of sedimentary manganese oxides between sub-oxic and oxic sediments and pore waters. The recycling processes result in a surface sediment cobalt trap.

We now focus on the recycling between oxic and sub-oxic sediment zones and test the coherence of the pore water and sediment data shown in Fig. 1. First, we calculate the flux of dissolved metal diffusing upward from the cobalt remobilization zone in sub-oxic sediments to surface oxic sediments. Then, we compare this flux with the accumulation rate of 'excess' metal in surface sediments. 'Excess' metal is defined as the difference between the mean metal sediment content in the top 7 cm of oxic sediment and the asymptotic metal concentration in anoxic sediments (Table 2). The calculations are summarized in Table 3 and indicate that for both manganese and cobalt, the 'excess' accumulation rate of metal calculated from the 'leach' sediment data accounts for most 'excess' metal accumulation calculated from 'total' sediment concentrations. These 'excess' metal accumulation rate estimates are comparable with the upward flux of metal through pore water to surface oxic sediments, indicating that the recycling of metal between pore waters and surface sediments is in an apparent steady state and is a contemporary oceanographic feature. A measure of the extent of metal recycling between sediments and pore fluids is provided by comparing the dissolved manganese (160 nmol cm^{-2} yr^{-1}) and cobalt (0.5 nmol cm^{-2} yr^{-1}) fluxes upward through pore waters (Table 3) with the mean total manganese (160 nmol cm^{-2} yr^{-1}) and cobalt (1.1 nmol cm^{-2} yr^{-1}) sedimentation rates (mean total metal content × sedimentation rate × *in situ* dry density) in the top 7 cm of sediments. (Note the distinction between total mean sedimentation rate used here and 'excess' accumulation rate defined in Table 3.) These comparisons suggest that large fractions of the solid phase cobalt and the manganese settling into the remobilization zone are recycled through pore waters to surface oxic sediments at this rapidly sedimenting Continental Rise site.

During early diagenesis in sediments the behaviour of cobalt is, therefore, similar to that of nickel[19]. Both cobalt and nickel are released to pore waters in the manganese reduction zone and recycled between oxic and sub-oxic sediments and pore waters. This type of recycling is in contrast to that of copper where remineralization occurs primarily in the oxygen reduction zone, and most copper is recycled between oxic sediments and pore waters and overlying deep oceanic waters[19].

Contribution of gaseous sulphur from salt marshes to the global sulphur cycle

P. A. Steudler & B. J. Peterson

The Ecosystems Center, Marine Biological Laboratory, Woods Hole, Massachusetts 02543, USA

Salt marshes have high rates of sulphide production due to dissimilatory sulphate reduction[1,2]; and because their anaerobic sediments are exposed to the atmosphere, they are thought to be important sites of biogenic sulphur emission[3,4]. We report here a synthesis of the results of an annual set of monthly flux measurements of hydrogen sulphide (H_2S), dimethyl sulphide (DMS), carbonyl sulphide (COS), carbon disulphide (CS_2) and dimethyl disulphide (DMDS) from a *Spartina* marsh and an adjacent tidal creek. Dimethyl sulphide and H_2S were the predominant gases released from the *Spartina* marsh (49% and 35% of the total, respectively) while H_2S was the major gas (71%) emitted from the creek site. We suggest that the short-lived sulphur gases released from marshes may have an important role in local atmospheric sulphur budgets. Globally, saline marshes may release a total of 1.7 Tg S yr^{-1} (1 Tg = 10^{12} g) into the atmosphere, which includes more than double the quantity of two important long-lived sulphur gases, COS and CS_2, needed to sustain the stratospheric sulphate layer.

Gaseous sulphur flux measurements were made using a FEP Teflon flow-through chamber[5] which covered the sediment or water surface. Ambient air was continuously drawn through the chamber at a velocity of 0.12 m s^{-1} and the difference between the gaseous sulphur concentrations in the chamber input and output air was used to determine the net uptake or release of the sulphur gases. This chamber design allowed the sulphur gases in the incoming ambient air to interact with the grass, sediment, or water surfaces so that net fluxes (emission minus uptake) were measured.

The volatile sulphur compounds were collected in the field from the chamber input and output air streams with glass tube traps packed with the solid adsorbents Molecular Sieve 5A and Tenax GC[6]. The chamber air streams were sampled at 40–100 cm^3 min^{-1} for 1–2 h depending on the anticipated sulphur concentrations for the sampling date. In the laboratory, the sulphur species were thermally desorbed from the trap, separated by temperature programming a Chromosil 330 column (10 foot × $\frac{1}{8}$ inch) and the amounts measured by a sulphur specific flame photometric detector[6]. Trap recoveries were determined with humid air (30–95% RH) to mimic field conditions.

We measured the gaseous sulphur fluxes during 1979 and 1980 from a short *Spartina alterniflora* marsh[5] and from an adjacent tidal creek (our unpublished work) in Great Sippewissett Marsh, Falmouth, Massachusetts. The sulphur fluxes from the *Spartina* site were measured with the grass intact and the chamber sealed to the peat surface. The fluxes from the creek site were obtained with a chamber which either rested on the creek sediment or floated on the surface of the tidal water. Each sampling usually consisted of a series of 1-h flux measurements made continuously for two consecutive tidal cycles (26 h) to obtain a daily flux estimate. The samplings were done at least once a month from February through December at the marsh site and from May through December at the creek site. We assumed that there were negligible releases in January from the *Spartina* site. Emission rates from the creek site for March and April were assumed to be equal to the rate measured in May. The creek site was ice covered (15 cm) in January and February so that flux measurements were not possible. We assumed negligible releases for those two months. We did not structure the sampling design to examine specifically the effects of the diurnal or tidal cycles on the emissions, but we included a variety of tidal and day-night regimes to obtain unbiased annual flux estimates.

Dimethyl sulphide and H_2S were the major components released from the *Spartina* site while H_2S was the major compound released from the creek site (Table 1). We calculated the annual sulphur emissions from Great Sippewissett marsh by weighting equally the daily fluxes from the *Spartina* and creek sites and then extrapolating to monthly fluxes. Maximum emission of each of the individual sulphur gases did not coincide but occurred from July through October (Fig. 1). Emissions during the summer and autumn months (June through October) accounted for 73% of the total release. We estimated a total emission from the marsh of ~4.5 g S m^{-2} yr^{-1} with H_2S (48%) and DMS (33%) the predominant sulphur gases emitted.

As the major gases released from marshes are short-lived compounds, H_2S, DMS and DMDS, the rapid tropospheric oxidation of these gases might be expected to produce elevated atmospheric levels of SO_2 and SO_4 in the vicinity of marshes. This could be important in locations where marshes constitute a large fraction of the land area. For example, Reisinger and Crawford[7] have hypothesized that marshes in the southern coastal US have an important role in the atmospheric sulphate concentrations in the Tennessee Valley.

Comparison of salt marsh sulphur fluxes with other biogenic sulphur sources (Table 2) indicates that marshes have the highest areal gaseous sulphur emissions with rates at least 10- to 100-fold greater than the emissions from oceans or inland soils. We estimated the inland soil emissions (Table 2) using the data reported by Adams *et al.*[8] from an extensive survey of sulphur fluxes from eastern US soils. We combined the average measured fluxes, which included some seasonal measurements (April through November), from 29 locations for seven different non-swamp (aerobic) soil orders and took the mean values. We also

Table 1 Annual gaseous sulphur emissions from the *Spartina* and tidal creek sites (g S m^{-2} yr^{-1})

	Spartina site	Tidal creek
H_2S	2.05	2.32
DMS	2.87	0.16
COS	0.30	0.34
CS_2	0.16	0.20
DMDS	0.42	0.25
Total	5.80	3.27

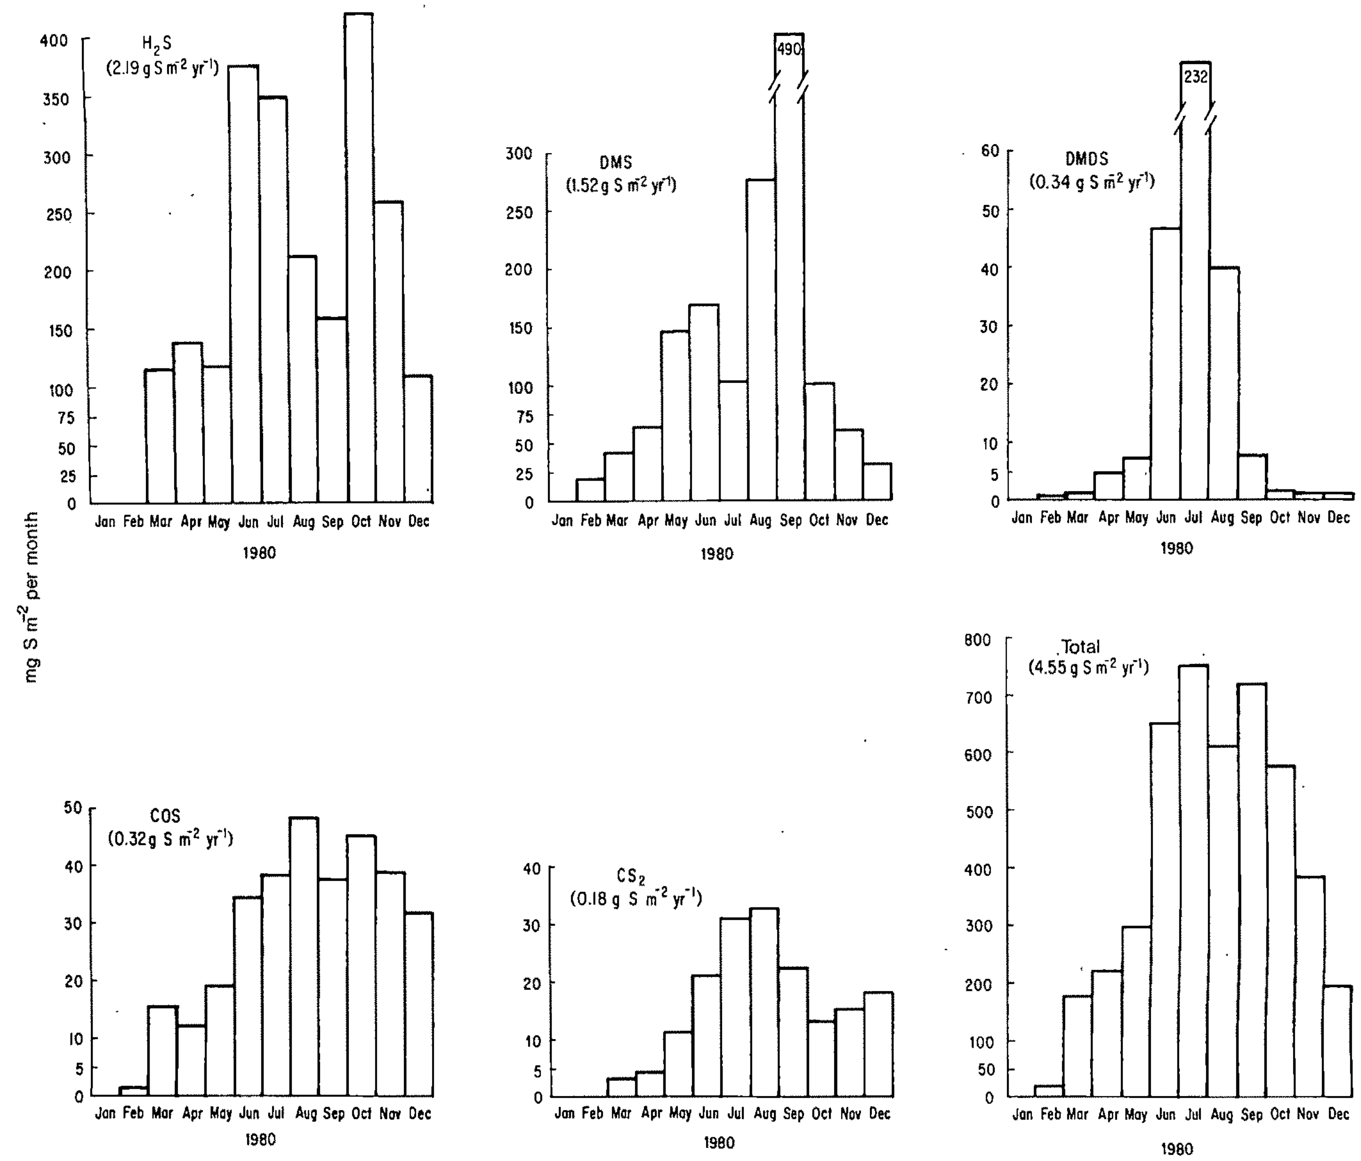

Fig. 1 Annual cycle of monthly fluxes for the individual sulphur gases and the total monthly release for Great Sipperwissett Marsh. Note that the flux rate scales are different.

adjusted each of the mean annual fluxes by increasing them two-fold (D. F. Adams, personal communication) because the data reported for inland soils were believed to represent minimum values[9].

A global estimate of the biogenic sulphur released from saline marshes can be calculated if we assume that: (1) all marshes have the same emission rates as Sippewissett Marsh; (2) the global marsh area[10] is 3.8×10^{11} m^2; (3) marshes are divided equally into vegetated areas and open-water areas of creeks and channels. We estimate that marshes release a total of 1.7 Tg S yr^{-1} to the troposphere of which 81% are the short-lived species H_2S (0.83 Tg S) and DMS (0.58 Tg S) with the remainder as DMDS (0.13 Tg S), COS (0.12 Tg S) and CS_2 (0.07 Tg S). Our value of 1.7 Tg S for the total global release from marshes is about half the 4.1 Tg S estimated by Aneja *et al.*[11] for the mean average global emission from saline marshes. In comparison, releases from the coastal regions which includes marshes, estuaries and coastal waters given in the most recent global budgets[12,13] range from 5 to 12 Tg S yr^{-1}. Thus, marshes by our estimate could contribute between 14 and 34% of the coastal estimates. Emissions from estuarine and coastal waters also contribute to the coastal region flux but the sulphur speciation and rates of release would probably be different than the sulphur gases emitted from marsh creek waters with more DMS[14] and much less H_2S released. However, there have not been any detailed emission studies from estuarine or coastal waters to verify this hypothesis. Recent estimates of the total global biotic release[13,15,16] range from 32 to 103 Tg S yr^{-1}. Marshes, therefore, would contribute only a small portion (1.6–5.4%) to the global biogenic emission.

Table 2 Annual gaseous sulphur emissions from natural sources

Source	Sulphur compound (g S m^{-2} yr^{-1}) H_2S	DMS	COS	CS_2	DMDS	Total
Oceanic	—	0.105[16]	0.0011[25,26]	0.00083[27]	—	0.1069
Inland non-swamp soils (derived from ref. 8)	0.0970	0.0070	0.0156	0.0232	0.0016	0.1444
Salt marshes (this paper)	2.19	1.52	0.32	0.18	0.34	4.55

While the emissions of COS and CS_2 are only a minor fraction (9.6%) of the total gaseous sulphur release they may have an important role globally. One reason is because COS and CS_2 are long-lived sulphur species with tropospheric lifetimes of ~1 yr and 1 month, respectively. Carbonyl sulphide, the most abundant sulphur gas in the atmosphere[17], has been proposed by Crutzen[18] to be the dominant sulphur source for the stratospheric aerosol layer during non-volcanic periods. An additional atmospheric source of COS results from the photooxidation of some portion of the CS_2 in the troposphere[19] because photooxidation of CS_2 yields one molcule each of COS and SO_2. Table 3 inventories COS, CS_2 and total sulphur emissions from natural sources including our estimate from marshes. The continental soil emissions were calculated using a global area[20] of 120.5×10^{12} m^2 (excluding lakes, streams, swamps, rocks, ice and sand) and the data in Table 2. We used 367.1×10^{12} m^2 as the global area of the oceans[16]. We estimate that marshes may release a total of 0.16 Tg S yr^{-1} (COS and CS_2 converted to COS) to the troposphere. The release from marshes is approximately two-fold larger than the quantity needed to maintain the stratospheric sulphate aerosol, but inland soils appear to be an even larger source.

We believe there is a global natural release of ~5.6 Tg S yr^{-1} as COS plus CS_2 (Table 3) which is in good agreement with several recent estimates of the total annual emission (natural plus anthropogenic) of ~5 Tg S (refs 12, 21). Thus, natural and, especially, biogenic sources appear to dominate the global atmospheric COS plus CS_2 cycle. Inland soils appear to be the major biotic source of COS plus CS_2 (84%) to the troposphere with about 4.7 Tg S yr^{-1} released from this source (Table 3). Our estimate of 3.2 Tg S yr^{-1} for the biogenic emission of CS_2 falls within the range of 1.5–5.8 Tg S calculated for a total global CS_2 source by Wine *et al.*[19] from atmospheric CS_2 abundances and modelling. If all the CS_2 is converted to COS, this would increase the natural tropospheric COS source to a maximum of ~4.0 Tg S yr^{-1} available for reaction with OH (ref. 22), long wavelength photodissociation[23] and other sinks or for transport of ~0.08 Tg S yr^{-1} to the stratosphere. Our estimate of 2.4 Tg S yr^{-1} for the direct COS emission from biogenic sources is much larger than the 0.5 Tg S yr^{-1} estimated by Turco *et al.*[21] to arise from biospheric processes. The difference in the estimates is due to our inclusion of recent data on the releases from marshes and soils and the change of the oceans from a sink to a source of these gases.

From the data in Table 2, we calculate that there is a global biogenic release of ~58 Tg S yr^{-1} to the atmosphere (Table 3). This value is well within the three-fold range of 32–103 Tg S yr^{-1} cited previously. Our global biogenic estimate is about half the recently calculated global anthropogenic SO_2 emission of 113 Tg S yr^{-1} (ref. 12). Biogenic oceanic emissions might be as large as 39 Tg S yr^{-1} predominately as DMS (98%) while inland soils may release ~17 Tg S yr^{-1} mostly as H_2S (67%). Ryaboshapko[12], in a recent global sulphur budget, calculated an annual bioemission from the land surface of 16 Tg S which is very close to our soils flux value (Table 3). Our estimate of the H_2S flux from soils of 11.7 Tg S yr^{-1} compares well with the 14 Tg S of H_2S estimated by Delmas *et al.*[24] to be emitted from aerobic soils. Our estimates suggest that oceanic DMS fluxes might be the single largest natural source (66%) of biogenic sulphur to the lower troposphere.

Emission of gaseous sulphur compounds from salt marshes are higher, per unit area, by one or two orders of magnitude than emissions from other ecosystems. However, because of the small global area of salt marshes, gaseous sulphur emissions from this source appear to contribute a minor fraction to the global emissions. Saline marsh releases of the short-lived sulphur gases (DMS, H_2S and DMDS) may have an important role in the atmospheric sulphur cycle on a local scale where the areal extent of marshes is large. Biotic emissions seem to be the dominant global source of long-lived sulphur gases, COS and CS_2, with a major fraction of the release originating from inland soils. Additional measurements of sulphur gas emissions from coastal oceans, soils (especially tropical soils) and forests are needed to refine the global biogenic emission estimates.

Table 3 Global release of COS, CS_2 and total sulphur emissions from natural sources (Tg S yr^{-1})

Source	COS	CS_2	Total sulphur emissions

Functional neuronal replacement by grafted striatal neurones in the ibotenic acid-lesioned rat striatum

O. Isacson, P. Brundin, P. A. T. Kelly[*], F. H. Gage & A. Björklund

Department of Histology, University of Lund, Biskopsgatan 5,
S-223 62 Lund, Sweden

In rats, striatal neuronal destruction by so-called excitotoxic amino acids, kainic acid or ibotenic acid (IA) produce neuropathological and neurochemical changes in the basal ganglia[1–4] which resemble those seen in patients with Huntington's chorea[5,6]. Such lesioned animals show a behavioural syndrome which is reminiscent of the cardinal symptoms of the disease[7–12], accompanied by a substantial increase in local cerebral metabolic activity in several striatal target structures within the extrapyramidal motor system[13–15]. The study was designed to explore the potential of grafted fetal striatal neurones implanted into the IA-lesioned striatum to compensate for the structural, neurochemical, metabolic and behavioural defects of IA-lesioned rats. Extending previous studies[16,17], we report here that such striatal implants can significantly ameliorate the lesion-induced locomotor hyperactivity and at least partly normalize the metabolic hyperactivity in the extrapyramidal neuronal system.

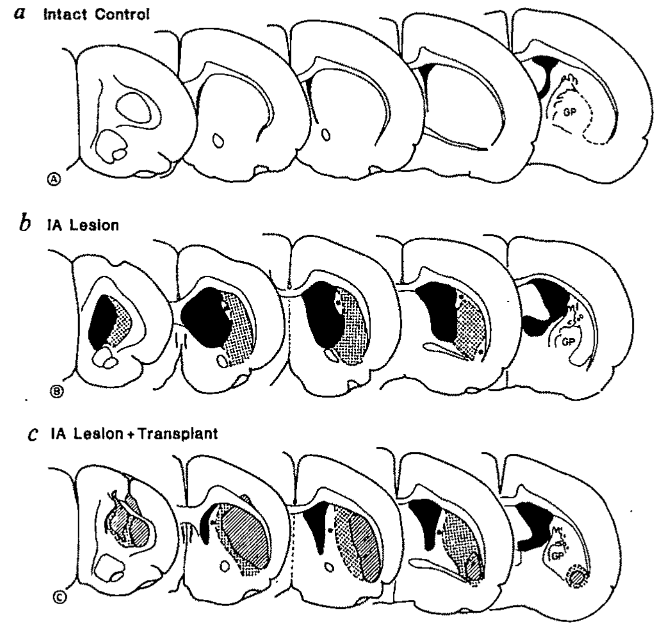

Fig. 1 Camera lucida drawings of a normal control rat (*a*), an IA-lesioned rat (*b*) and an IA-lesioned and grafted rat (*c*) 11 weeks after the lesion. The double-cross-hatched areas represent the scar tissue, the asterisks the areas of neuronal sparing and the black areas the lateral ventricle. The graft tissue in *c* is represented by the single-cross-hatched area. GP, globus pallidus.

Methods: 53 Female Sprague–Dawley rats, 180–200 g in weight, were used in this study. 13 Rats were unoperated controls; the remaining 40 were anaesthetized with methohexital barbiturate (Lilly) and mounted in a stereotaxic frame. Part of the cranium anterolateral to bregma was carefully removed by drilling, and a total of 20 μg of IA (Natural Products Ltd) in 1 μl of phosphate buffer (*p*H 7.4) was injected at four stereotaxically defined sites in the right caudate-putamen (A 0.4, L 3.9, V 5.3; A 0.4, L 3.1, V 4.0; A 1.3, L 3.1, V 4.4; A 1.3, L 2.0, V 4.3; all coordinates in mm, anterior and lateral coordinates from bregma, ventral coordinates from dural surface). Each of the four 0.25-μl microinjections was performed over a total of 10 min before the needle was slowly withdrawn. 5–7 Days after the IA lesion, 20 of the rats were selected at random to receive implantations of cell suspensions prepared from primordial striatum taken from rat fetuses of 13–15 days gestational age, as described previously[16]. Primordial striatal tissue was collected in 0.6% glucose in saline at room temperature and then transferred to a similar glucose solution with the addition of 0.1% trypsin (crude type II, Sigma), in which incubation took place at 37 °C for 15–20 min. At the end of the incubation period the trypsin medium was removed and the tissue rinsed four times with fresh glucose–saline solution. The tissue pieces were then mechanically dissociated with a fire-polished Pasteur pipette (diameter ~1 mm) in a volume equivalent to 10 μl per two striatal primordia. 1 μl suspension was injected over 1 min at each of the four sites which had previously received IA. After each injection the needle was left in position for an additional 2 min before being slowly withdrawn.

Our experimental rats (Fig. 1) was divided into three groups. One group, consisting of five lesioned, five lesioned and grafted and seven unoperated control rats, was used for measurements of local glucose utilization, according to the autoradiographic ^{14}C-2-D-deoxyglucose (^{14}C-2-DG) method of Sokoloff *et al.*[18]. We also used these brains for histology and morphometry of the grafts and the host striatal structures. The second group, consisting of six lesioned and five lesioned and grafted rats, was used for measurements of glutamic acid decarboxylase (GAD)[19] in the graft and the host striatum on the lesioned and control sides. The third group, consisting of nine lesioned, ten lesioned and grafted and six control rats, was used for analysis of locomotor activity.

The IA lesion caused an average reduction of ~65% in the volume of the head of the caudate-putamen accompanied by an average sevenfold increase in the volume of the lateral ventricle at the same cross-sectional levels (Fig. 1). The Klüver–Barrera stain revealed a severe loss of striatal neurones; only about 5–10% of the original volume of the head of the caudate-putamen showed sparing of neurones. The remaining tissue was virtually free of stainable neurones and had the appearance of a glial scar penetrated by the seemingly undamaged fibre bundles of the internal capsule. The spared neurones occurred as a rim along the ventricular surface and along the external capsule in the caudal aspects of the lesion (Fig. 1*b*). The nucleus accumbens and the tail of the caudate-putamen were only marginally affected; in most cases there were only minor signs of cell damage along the needle tracks in the cortex. Probably as a secondary consequence of the lesion[6,20], both globus pallidus and pars reticulata of the substantia nigra underwent a marked shrinkage on the lesioned side[20,21].

The GAD assay revealed an average depletion of the γ-aminobutyric acid (GABA) synthesizing enzyme concentration of 58% in the head of the caudate-putamen encompassing the lesion, from 76.9 ± 5.5 to 32.3 ± 8.4 nmol per h per mg protein. Taking into account the volume reduction of the caudate-putamen, we estimated the depletion of the total GAD content in the head of the caudate-putamen to be ~85%.

The striatal implant had an average volume of about 4 mm^3 (range 2–7 mm^3), which resulted in an average increase of 50% in the lesioned caudate-putamen volume. The amount of caudate tissue with signs of sparing, and the volume of the scar tissue were very similar in the lesion and the lesion + graft groups (5% compared with 6%; and 28% compared with 31%, respectively; Fig. 1*b*, *c*). Microscopically, the implant appeared as one or several neurone-rich cell masses sometimes extending along the needle tracks up into the overlying cortex (Fig. 1*c*). In the animals taken for neurochemical analysis, we found that the GAD level of the graft tissue was as high as that of the normal caudate-putamen (83.4 ± 9.0 nmol per h per mg protein), and in a parallel immunohistochemical study[21] the striatal grafts contained many of the chemically identified neurone types normally present in the neostriatum.

In the ^{14}C-2-DG autoradiography (Table 1), we found that the IA lesion caused a 60% reduction in glucose utilization throughout the lesioned caudate-putamen. The partially spared medial portion displayed smaller reductions (22%), while the

Local ^{14}C-2-deoxy-D-glucose utilization after unilateral IA lesion ($n=5$) or IA lesion plus striatal suspension grafts ($n=5$). A group of seven age- and weight-matched unoperated female rats served as the control group. No side-to-side differences were observed within any brain structure in the intact animals, so the two sides were pooled to provide a single control value. Structures measured were sampled according to Schwartz and Sharp[31]. No transplant-induced effects were observed in other brain areas.

Methods: Under light halothane anaesthesia (1% in a 7:3 $N_2O_2:O_2$ gas mixture), both femoral arteries and one femoral vein were cannulated. Groin incision sites were infiltrated with local anaesthetic (xylocaine) and sutured. A loose-fitting plaster cast was applied around the lower body and hind legs, taking care not to impair thoracic movements, and the cast was taped to lead weights. Thus restrained, anaesthesia was discontinued and at least 2 h were allowed to elapse before proceeding with the experiments. The measurement was initiated with a 30-s intravenous injection of 0.5 ml ^{14}C-labelled 2-deoxy-D-glucose (125 μCi kg^{-1}, NEN). Over the subsequent 45 min, a total of 14 timed arterial blood samples were collected and the plasma separated from the cellular fraction by immediate centrifugation. Aliquots of the plasma were taken for measurement of glucose levels (10 μl) and ^{14}C concentrations (20 μl). At the end of 45 min the animals were decapitated and their brains were rapidly dissected and frozen in isopentane at −50 °C. Autoradiograms were prepared from ~150 coronal cryostat sections (20 μm) from each brain mounted on glass coverslips. The sections were placed in a light-tight X-ray cassette, together with a set of seven ^{14}C-containing plastic standards (concentrations 48–1,061 nCi per g tissue equivalents) in close apposition to a sheet of X-ray film (Kodak SB-5) for 7 days. The processed films were analysed densitometrically using a Leitz TAS plus computerized densitometer. Local cerebral glucose utilization was calculated according to Sokoloff *et al.*[18].

* Significantly different from intact control value ($P<0.05$); †, significantly different from IA lesion alone ($P<0.05$). One-way analysis of variance with post-hoc Neuman–Keuls test. No symbol indicates $P>0.05$.

spared tail of the caudate was unaffected. In contrast to the ipsilateral decreases, the contralateral caudate-putamen displayed increased mean glucose utilization values of between 19 and 28% over intact control levels in the different caudate regions measured. All major primary and secondary projection areas of the neostriatal efferents (Fig. 2) showed significant uni- or bilateral increases in glucose use. The strongest increases were seen in the pars reticulata of the substantia nigra (+49% and 29% on the ipsi- and contralateral sides, respectively), in the globus pallidus (+26% and 29%), in the subthalamic nucleus (+18% and 19%) and in the deep superior colliculus (+17% and 18%). Bilateral increases were seen also in several areas functionally associated with the extrapyramidal motor system, such as the ventral tegmental area, nucleus accumbens, sensorimotor cortex and nucleus ruber, whereas other cortical and brain-stem regions remained unaffected.

The striatal implant proper exhibited a significant ^{14}C-2-DG utilization of 69±3% of the intact control neostriatum. The implant does not influence glucose use in the surrounding, lesioned or spared areas of the host caudate-putamen, although the contralateral increases in glucose use in animals with IA lesions alone were attenuated enough to be no longer significantly different from the intact controls (Table 1).

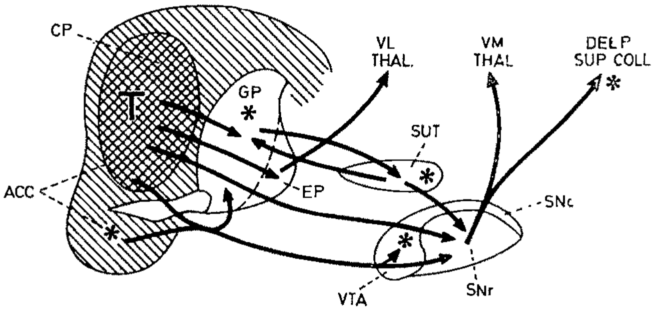

Fig. 2 Principal arrangements of the major output pathways from the caudate-putamen and nucleus accumbens. Those primary and secondary targets which exhibited graft-induced reductions in ^{14}C-2-DG utilization are marked by asterisks. ACC, nucleus accumbens; CP, caudate-putamen; EP, entopeduncular nucleus; GP, globus pallidus; SN, substantia nigra (c, compacta, r, reticulata); SUT, subthalamic nucleus; VL and VM Thal, ventrolateral and ventromedial thalamic nuclei; VTA, ventral tegmental area.

The hypermetabolic responses in the primary and secondary striatal projection areas were normalized by the implant ipsilaterally in the globus pallidus and subthalamic nucleus and bilaterally in the deep superior colliculi († in Table 1; * in Fig. 2). In the functionally associated areas, a significant transplant-induced effect was also seen in the VTA and nucleus accumbens. No transplant-induced effects were observed elsewhere in the brain.

Locomotor activity was measured in two different tests (Table 2). Previous studies[8,10] have shown that rats with excitotoxic striatal lesions are hyperactive only when tested during their active period at night (when rats normally express about 90% of their diurnal locomotor activity[22]) or under food deprivation. Consistent with these reports, the IA-lesioned animals in the present study were significantly hyperactive in the open field when tested overnight under temporary (24 h) food and water deprivation. In agreement with previous findings[17], the locomotor hyperactivity was compensated for completely in the animals with IA lesions plus striatal transplants ($P < 0.01$). These effects were also confirmed when locomotor activity was measured in rotometer bowls (Table 2); the individual scores recorded in the two tests were highly correlated ($r = 0.8$; $t = 5.05$). The rotometer test showed, moreover, that although the unilateral IA lesion caused spontaneous turning behaviour (in the direction towards the lesion) during the first few days after lesion, the motor asymmetry was no longer evident in any of the lesioned or grafted groups by 10–12 weeks after the operation.

The present results thus demonstrate that the striatal suspension grafts not only survive and differentiate within the host neostriatum previously depleted of its constituent neurones by IA, but that they are also capable of compensating for the nocturnal locomotor hyperactivity and the extrapyramidal metabolic hyperactivity seen in the unilaterally IA-lesioned animals. The exact mechanism of these transplant-induced effects are unknown. Previous experiments with implants of catecholamine-producing cell systems[23–28] have provided evidence that intracerebral grafts can exert their functional effects in the host brain both via direct axonal connections with previously denervated elements in the host target, and via a more diffuse release of the active compound into the host tissue or the cerebrospinal fluid. Both these mechanisms seem consistent with our present results. It thus seems possible that the striatal implants could exert a neurohumoral-like effect either on spared neurones in the caudate-putamen, or on parts of the nucleus accumbens in the neighbourhood of the graft, or perhaps even on more distant sites via a diffuse release of active compounds into the cerebrospinal fluid in the adjoining lateral ventricle. Alternatively, the grafted neurones might function via fibre connections established with striatal neurones in the host, either, for example, via a local fibre outgrowth into the spared portions of the striatum or nucleus accumbens, or via fibres growing over somewhat longer distances to reach, for example, the globus pallidus. Evidence for such effects of the striatal implants will, however, require further studies on the connectivity of the grafted neurones.

Table 2 Transplant-induced effects on locomotor activity of IA-lesioned rats

Groups	Overnight activity (total photocell counts)	Overnight turning in rotometer	
		Total half-turns	Side-bias (% turns in ipsilateral direction)
Control	7,232±380	142.0±28.7	44.8±9.6
IA lesion	12,273±1,842*	336.0±49.4*	58.7±8.2
IA lesion +transplant	6,485±467†	170.0±27.2†	49.8±8.2

Overnight locomotor activity measured in enclosed automated activity boxes (50 × 50 cm), connected to a microprocessor. Values represent the mean total photocell counts ±s.e.m. over a 13-h test period (1830–0730 h). 10–11 weeks after IA lesion and transplantation, rats from the three groups were randomly selected for activity tests. Before the test session, rats were temporarily deprived of food and water for 24 h (see text). Statistical analysis: one-way analysis of variance, $F = 7.25$, post-hoc Neuman–Keuls. Overnight locomotor activity was measured in rotometer bowls of diameter 55 cm. Values represent the total number of half-turns ± s.e.m. over an 11-h period (1830–0530 h). Rats were temporarily deprived of food and water for 2–5 h before testing. Statistical analysis, one-way analysis of variance, $F = 6.33$, post-hoc Neuman–Keuls. Side-bias is expressed as turns in the ipsilateral direction to IA lesions divided by the total number of turns. Values show mean per cent ± s.e.m. for each group. One-way analysis of variance, $F = 0.59$.

* $P < 0.05$ compared with control; † $P < 0.05$ compared with IA lesion.

The increased glucose utilization seen in several primary and secondary neostriatal target areas in the IA-lesioned animals indicates that the neostriatum normally exerts an inhibitory tonic action on the functional activity of these structures. Interestingly, it has previously been shown that the increases in glucose utilization induced by excitotoxic lesions of the neostriatum can be attenuated by systemic injections of the GABA receptor agonist, muscimol[29], and that it is possible to modify locomotor activity in rats by local administration of GABA receptor-active drugs directly into the globus pallidus[30]. Against this background it may be sufficient for the striatal implants to reinstate a tonic and relatively nonspecific inhibition over the striatal output structures (perhaps via release of GABA or other neuromodulators from the graft) in order to compensate for the lesion-induced metabolic and locomotor hyperactivity in the IA-lesioned animals. More complex striatum-dependent behaviours, may, by contrast, require both temporally and spatially patterned cortical inputs and are thus less likely to be influenced by the implants unless they are capable of establishing ordered and relatively specific afferent and efferent connections with the host brain. Whether this will be possible to achieve with striatal implants is an interesting topic for further investigation.

The neostriatal mosaic: compartmentalization of corticostriatal input and striatonigral output systems

Charles R. Gerfen

Health, Bethesda, Maryland 20205, USA

The striatum (caudate-putamen) of the basal ganglia in the mammalian forebrain is a mosaic of two interdigitating, neurochemically distinct compartments. One type, the 'patch' compartment, is identified by patches of dense opiate receptor binding[1,2], and is enriched in enkephalin- and substance P-like immunoreactivity[3]. The other compartment, the 'matrix', has a high acetylcholinesterase activity[2,4], and is shown here to have a dense plexus of fibres displaying somatostatin-like immunoreactivity. The present study demonstrates the two compartments have distinct connections, using a method that concurrently reveals striatal input, output and neurochemical systems in the rat. Patches receive inputs from the prelimbic cortex (a medial frontal cortical area with direct 'limbic' inputs from the amygdala[5] and hippocampus[6,7]); they also project to the substantia nigra pars compacta (the source of the nigrostriatal dopaminergic system). Conversely, the matrix receives inputs from sensory and motor cortical areas[8]; here it is shown to project to the substantia nigra pars reticulata (the source of the non-dopaminergic nigrothalamic and nigrotectal system[9,10]). Also, an intrinsic striatal somatostatin-immunoreactive system is described that may provide a link between the two compartments. The striatal patch and matrix compartments thus appear to be functionally distinct and interactive parallel input–output processing channels.

The input-output organization of the striatum was examined using a method that concurrently demonstrates corticostriate systems (*Phaseolus vulgaris* leucoagglutinin (PHA-L) anterograde tracing[11]), striatonigral projection neurones (fluorescent retrograde tracer Fast blue[12]), and either the striatal patch (with enkephalin- or substance P-immunoreactivity[3]) or matrix (with somatostatin-immunoreactivity[13]) compartments. The anterogradely transported plant lectin PHA-L was injected iontophoretically into the right prelimbic cortex of eight female albino rats, as previously described[11]. These animals were also injected with 50 nl of the retrogradely transported fluorescent tracer Fast blue (in a 2.5% suspension) into the right substantia nigra. The animals received a left intraventricular injection of 75–100 μg colchicine 8 days after the tracer injections and 2 days later were perfused under chloral hydrate anaesthesia with 0.9% saline followed by 4% formaldehyde in 0.1 M acetate buffer (*p*H 6.5) and then 4% formaldehyde in 0.1 M borate buffer (*p*H 9.5) (ref. 14). The brains were removed and stored overnight in the last solution plus 20% sucrose. Coronal 30-μm-thick sections were cut on a freezing microtome, and sections through the substantia nigra examined to reconstruct the site of the Fast blue injections. The other sections were incubated overnight at 4 °C in 0.4% Triton X-100 plus 2% normal goat serum (NGS) in 0.02 M potassium phosphate-buffered saline (KPBS, *p*H 7.4), and then incubated at 4 °C for 24–48 h in a 1:1,000 dilution of guinea pig antisera directed against PHA-L in KPBS plus 2% NGS. These sections were then rinsed in KPBS and incubated at 4 °C for 24–48 h in rabbit antisera directed against either substance-P (1:3,000, a gift of M. Brown), Leu-enkephalin (1:2,000, Immunonuclear, Inc.), or somatostatin[13] (SS28 (1–12), 1:5,000 + SS28, 1:2,000, a gift of R. Benoit). After rinsing for 30 min, the primary antisera were localized by incubating the sections in a mixture of affinity purified fluorescein-labelled goat anti-guinea pig IgG (GAGP-FITC, 1:100, Cappel) and affinity purified tetramethylrhodamine-labelled goat anti-rabbit IgG (GAR-TRITC, 1:100; Sigma) in KPBS plus 0.3% Triton X-100 and 2% NGS for 45 min. Sections were examined with a Nikon fluorescent microscope. Sections incubated with one or the other labelled antisera demonstrated no cross-reactivity with the inappropriate primary antisera. Preadsorption of each antiserum with 1 mg ml^{-1} of the homologous

---

* Present address.

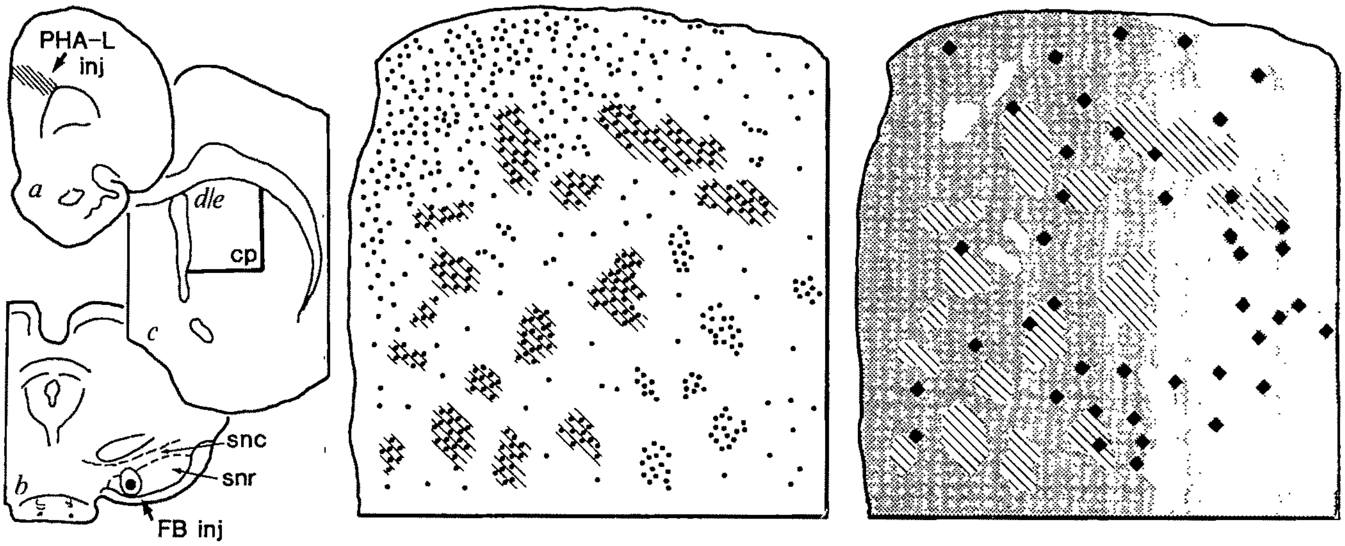

Fig. 1 Diagrammatic representation of labelling in coronal sections from case CSI-4. *a*, The location of PHA-L injection site (PHA-L inj) in the prelimbic cortex shown by hatching. *b*, The location of the Fast blue injection (FB inj) centred in the ventro-medial substantia nigra pars reticulata (snr) with spread into the pars compacta is marked (O). The area within the medio-dorsal caudate-putamen (cp) outlined in section *c* is enlarged in *d* and *e*. *d*, Retrogradely labelled striatonigral projection neurones (dots) are most heavily concentrated in the most medio-dorsal area. Their distribution here is relatively homogeneous, but ventral distribution is in discrete clusters, some of which are co-extensive with patches of labelled corticostriate afferents marked with hatching. *e*, The concurrent localization of somatostatin-immunoreactive cell bodies (diamonds) shows that such neurones are located both within and around patches of PHA-L labelled corticostriatal input (hatching), but that somatostatin-immunoreactive fibres (shaded area) appear to be limited to the matrix zone complementary to such patches. In this example, the prelimbic input is primarily to the medial half of the striatum; in two other cases where the PHA-L injection was into a more-rostral part of the prelimbic cortex, and labelled corticostriate inputs are distributed to the patches in the lateral half of the striatum.

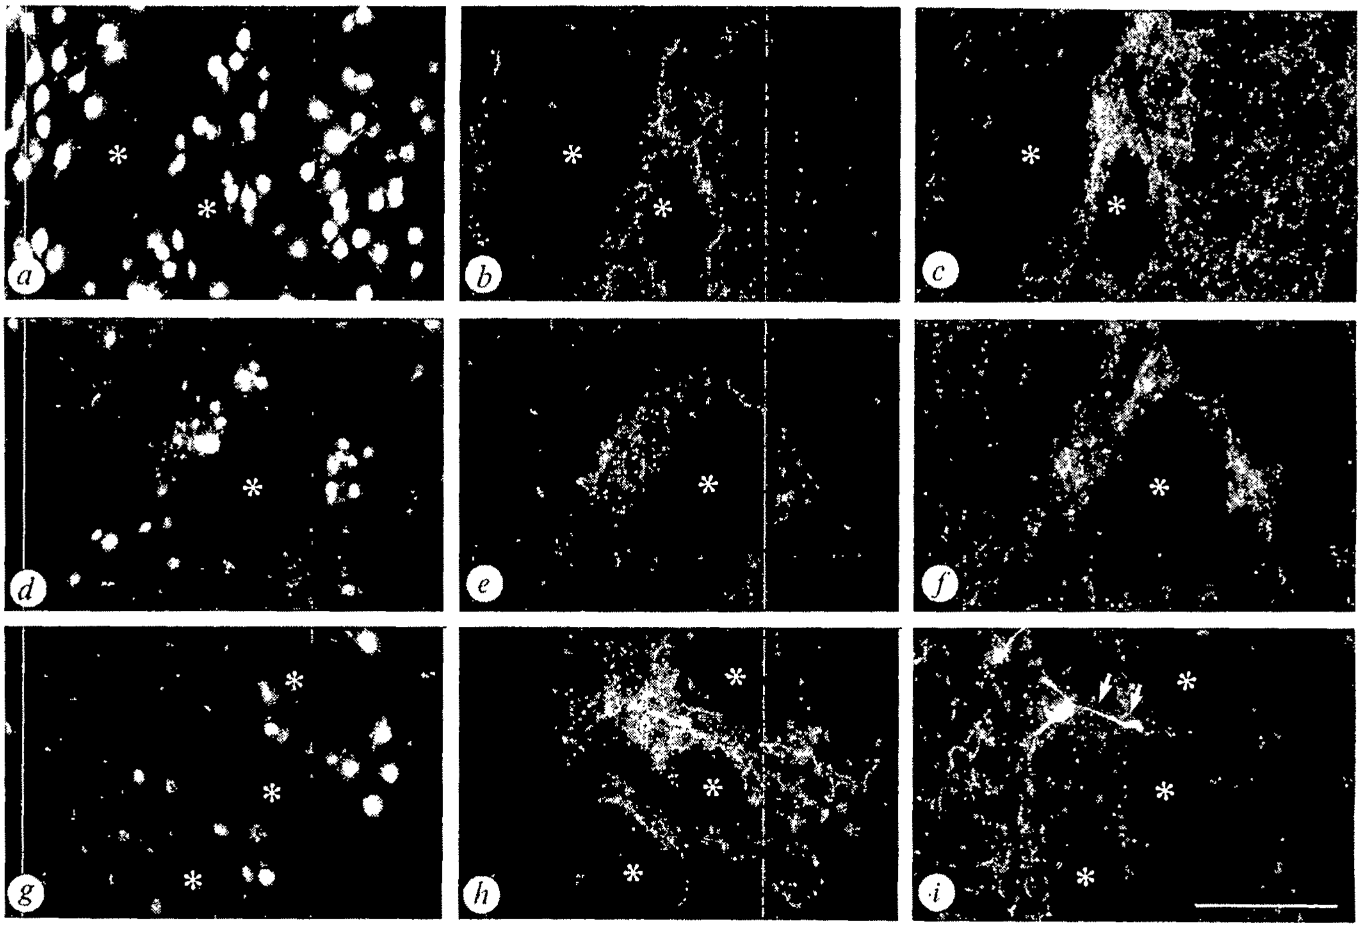

Fig. 2 Photomicrographs of striatal areas in three sections, *a–c*, *d–f*, and *g–i*, from case CSI-4 showing concurrent localization of striatonigral projection neurones labelled with the fluorescent marker Fast blue (*a*, *d*, *g*); patches of corticostriate input labelled with PHA-L (*b*, *e*, *h*) demonstrated with fluorescein-labelled goat anti-guinea pig IgG (GAGP-FITC) and Leu-enkephalin (*c*), substance-P (*f*), and somatostatin-like (*i*) immunoreactivity demonstrated with tetramethylrhodamine-labelled goat anti-rabbit IgG (GAR-TRITC). In each section the three labels are separately revealed with the appropriate epifluorescent excitation filters (e.f.) and barrier filters (b.f.) of the following wavelengths: true blue (e.f., 330–380; b.f., 420), FITC (e.f., 460–485; b.f., 515–545) and TRITC (e.f., 535–550; b.f., 580). Asterisks mark unlabelled cortico-fugal fibre tracts used as landmarks to compare the relative distribution of the labelled structures in the same field. The striatal area *a–c* lies in the medio-dorsal striatum. Fast blue labelled neurones (*a*) are present both within the corticoreceptive (*b*)/Leu-enkephalin-immunoreactive rich (*c*) patch and in the surrounding matrix compartment. The area in another section (*d–f*) is in a more ventral part of the striatum, where a cluster of retrogradely labelled striatonigral neurones (*d*) is co-extensive with a patch of PHA-L labelled corticostriate fibres and terminals (*e*) and a patch of substance P-immunoreactivity (*f*). In an adjacent section (*g–i*), in the same area of the striatum as *d–f*, a cluster of retrogradely labelled striatonigral neurones is observed (*g*), co-extensive with labelled corticostriate afferents (*h*) which are distributed complementary to the surrounding matrix of somatostatin-like immunoreactive fibres and terminals (*i*). A single somatostatin immunoreactive neurone is observed at the border of the corticoreceptive patch area with a dendrite (arrows) the end of which is enlarged due to focal aberration) that extends into the patch area away from the somatostatin fibre plexus in the matrix. Scale bar, 100 μm.

peptide completely blocked specific staining in the neostriatum.

In six cases, PHA-L injections were localized to different 300-μm-wide areas in the prelimbic cortex[5] (Fig. 1*a*). Projections distributed throughout the striatum but restricted to the striatal patch system are seen when the results of these injections are combined. In the example shown in Figs 1 and 2, labelled corticostriate fibres and terminals are distributed in discrete patches, 5–15 per section, of diameter 100–400 μm and spread throughout the dorso-ventral and rostro-caudal extent of the medial half of the striatum. In this example, the Fast blue injection is centred in the medial substantia nigra pars reticulata with tracer spreading dorsally into the pars compacta (Fig. 1*b*). In the medio-dorsal striatum, retrogradely labelled neurones are homogeneously distributed in both the patch areas co-extensive with labelled prelimbic corticostriate inputs and in the complementary matrix (Figs 1*d*, 2*a–c*). Ventral to this area, labelled striatonigral projection neurones are distributed in discrete clusters (Fig. 2*d*, *g*) co-extensive with the patches of labelled corticostriate terminals (Fig. 2*e*, *h*). These patches (Fig. 2*b*, *e*) are always co-extensive with patches of strong Leu-enkephalin-immunoreactivity (Fig. 2*c*) and substance P-immunoreactivity (Fig. 2*f*). In a third series of sections, a somatostatin-immunoreactive fibre plexus appears only in the matrix compartment (Figs 1*e*, 2*g–i*). Somatostatin-immunoreactive neurones are present in both patches and matrix and often dendrites from matrix-labelled neurones extend into the patches. Labelled axons of patch somatostatin-immunoreactive neurones project into the surrounding matrix, where they ramify into a fibre plexus which has numerous 'terminal-like' swellings. Somatostatin immunoreactivity was never observed in Fast blue labelled striatal projection neurones.

To obtain a more detailed view of the distribution of retrogradely labelled striatonigral projection neurones relative to the striatal compartments, 12 animals were injected with 35 nl of Fast blue into the substantia nigra. Colchicine was administered intraventricularly in a dose of 75 μg on the sixth post-injection day and the animals were killed on the eighth day, when the brains were processed as described above. Cases were classified as having injections restricted primarily to the pars compacta ($n=3$), pars reticulata ($n=3$), or with equal spread into both

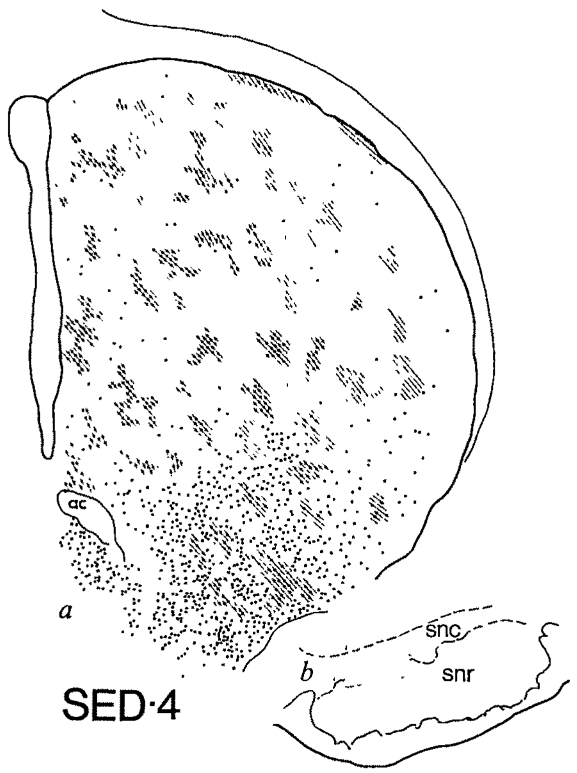

Fig. 3 *a*, A frontal section through the anterior striatum from case SED-4 onto which are mapped the distribution of substance P-like immunoreactive rich patches (hatching) and striatonigral projection neurones (dots), that are retrogradely labelled following an injection of Fast blue into the substantia nigra pars compacta (snc), shown diagrammatically in *b*. snr, Substantia nigra pars reticulata. Note that in the ventral striatum, labelled neurones are distributed in both the striatal patch and matrix compartments (see text), whereas dorsal to this area, labelled neurones are distributed in clusters that are co-extensive with patches of strong substance P-immunoreactivity.

areas ($n = 6$). Figure 3 shows the distribution of retrogradely labelled neurones relative to patches of substance P-immunoreactivity in one experiment in which the injection was centred in the medial pars compacta (snc, Fig. 3*b*). Labelled neurones are most densely distributed in the ventral striatum in both the patch and matrix compartments; outside this ventral zone and extending to the dorsal border of the striatum, labelled neurones are distributed preferentially in clusters co-extensive with patches of substance P-immunoreactivity. This pattern was evident throughout the rostrocaudal extent of the striatum and was typical in cases where injections were centred in the pars compacta. By contrast, when injections were centred in the pars reticulata, labelled neurones are most densely distributed in the matrix compartment throughout the dorsal striatum. However, the effective injection site cannot be determined using retrograde tracers, so these results must be viewed cautiously. In a recent study[15] (and C.R.G., in preparation) using PHA-L anterograde tract tracing, the dorsal striatum has been shown to give rise to a split nigral projection, one to the pars compact and a separate, denser one to the ventral pars reticulata. This result, combined with the retrograde data presented here, suggests that the projection neurones in the dorsal striatal patches are the source of fibres that innervate the pars compacta. These conclusions are consistent with ultrastructural data which demonstrate convergence of inputs from both the dorsal and ventral striatum onto pars compacta neurones[16].

Classical studies have linked the basal ganglia to sensorimotor function via the movement disorders produced by Parkinson's disease and Huntington's chorea[17]. More recently, involvement of this neural system in affective disorders such as schizophrenia has been suggested[18]. These dual functions of the striatum are thought to be regionally segregated to a ventral or 'limbic' striatal region that mediates striatal involvement in affective behaviour, and a dorsal or 'nonlimbic' striatal region involved in sensorimotor function[19,20]. The topographic organization of certain striatal input–output systems supports this view. The dorsal striatum, composed of the dorso-lateral part of the caudate-putamen, receives neocortical inputs from sensorimotor areas[21,22] and projects to the dorsal pallidum and substantia nigra pars reticulata[23,24]; the latter nucleus provides inputs to the thalamus, tectum and midbrain tegmentum[9,10]. The ventral striatum[19–21], composed of the nucleus accumbens, adjacent ventral caudate-putamen, and olfactory tubercle, receives limbic inputs from the amygdala and allocortex[5,6,19,21] and projects to the ventral extension of the pallidum (the substantia innominata, lateral preoptic area and lateral hypothalamus)[20,25]. Interactions between these striatal subsystems occurs via the convergence of their transynaptic output pathways to the thalamus[9,26] and the midbrain tegmentum[9,25,27], or via ventral striatal input to the substantia nigra pars compacta[23–25,28], which provides the nigrostriatal dopaminergic 'feedback' system to the dorsal striatum.

Recently the boundaries of the limbic striatum have been expanded to include the most medial part of the dorsal striatum, which receives inputs from the amygdala[21] and cingulate cortex[29]. However, these findings do not address the issue of possible interaction of limbic and non-limbic inputs within any given striatal district. The present results show that the prelimbic cortex, which receives direct limbic inputs from the amygdala[5] and hippocampus[6,7], projects to the patches throughout the striatum including the dorsolateral part that receives sensorimotor cortical inputs[8,21]. In this striatal region, sensory and motor cortical areas preferentially project to the matrix[8]. This suggests that, on the basis of extrinsic connections, the striatal patch and matrix are functionally distinct compartments. Furthermore, it is shown here that the striatal projection neurones in the patches project to the substantia nigra pars compacta whereas those in the matrix project to the substantia nigra pars reticulata. The somatostatin-immunoreactive intrinsic system provides a possible link between the two striatal compartments, with neurones in the patches providing inputs to the surrounding matrix areas. These findings suggest that the striatal patch and matrix compartments comprise a system of intermixed and interactive functionally distinct parallel input–output processing channels that are overlaid on the more classically recognized topographically ordered dorsal (non-limbic) and ventral (limbic) segregation of striatal connectivity and function[19–21,30].

Intraneuronal generation of a pyridinium metabolite may cause drug-induced parkinsonism

S. P. Markey, J. N. Johannessen, C. C. Chiueh, R. S. Burns & M. A. Herkenham*

Laboratory of Clinical Science and *Laboratory of Neurophysiology,
National Institute of Mental Health, NIH, Bethesda,
Maryland 20205, USA

The compound 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) induces an irreversible neurological syndrome in man[1,2] and monkey[3] which is similar to idiopathic Parkinson's disease in its clinical, pathological, neurochemical and pharmacological response properties. MPTP is selectively neurotoxic to the dopaminergic regions of the brain, destroying neurones in the substantia nigra (A8 and A9 cells, nigrostriatal system) but not the ventral tegmental area (A10 cells, mesolimbic system)[3]. Selective dopamine depletion and nigral cell loss after MPTP treatment has also been reported recently in the mouse[4]. The mechanism by which a peripherally administered, low-molecular weight compound exerts permanent but selective toxic effects on dopamine systems in the brain may be relevant to parkinsonian syndromes induced by other toxins and to the disease process in idiopathic Parkinson's disease. We report here that MPTP is oxidized in the brain to a pyridinium species (a compound with potent herbicidal activity) and, in the monkey, is trapped intraneuronally. Furthermore, we demonstrate that this enzymatic oxidation is blocked *in vivo* in the mouse by a monoamine oxidase inhibitor, a condition which also blocks the neurotoxicity[5], indicating that the oxidative metabolism of MPTP is required for its neurotoxic effect.

Radiolabelled [1-^{14}C]MPTP was prepared by reacting ^{14}C-methyl iodide (2 mCi, 5.4 mg) with 4-phenylpyridine (10 mg) in dichloromethane at room temperature for 24 h, followed by reduction of the dried residue in aqueous solution with excess $NaBH_4$, using the method of Lyle[6]. The product, [1-^{14}C]MPTP, was extracted into hexane, dried and reconstituted in ethanol for injection. Alternatively, excess 1-methyl-4-phenylpyridinium iodide (5.4 mg) was reduced with NaB^3H_4 (77.8 Ci mmol^{-1}, 0.24 mg) in aqueous base at room temperature for 2 h and the product, 2,6-$^3H_2$-MPTP (38 Ci mmol^{-1}), extracted into hexane, dried and reconstituted in ethanol.

Four rhesus monkeys were injected intravenously with various combinations of $^3H_2$-MPTP, ^{14}C-MPTP and unlabelled MPTP and killed between 1 and 20 days after injection (Table 1). After a lethal dose of pentobarbital, the brains were removed and bisected in the sagittal plane. The right half was rapidly frozen and processed for autoradiography in the coronal plane. The left half was dissected using gross anatomical landmarks and the pieces frozen and retained for chemical studies. Dissected regions were homogenized in water (1:4 w/v) and either solubilized with Protosol (NEN) for counting or extracted with ethanol for counting and HPLC of radioactive materials, as described in Fig. 1 legend. Twenty-eight adult male mice (NIH Swiss Webster, 20–22 g) were also used. Seven mice were injected intraperitoneally (i.p.) with saline and seven with pargyline

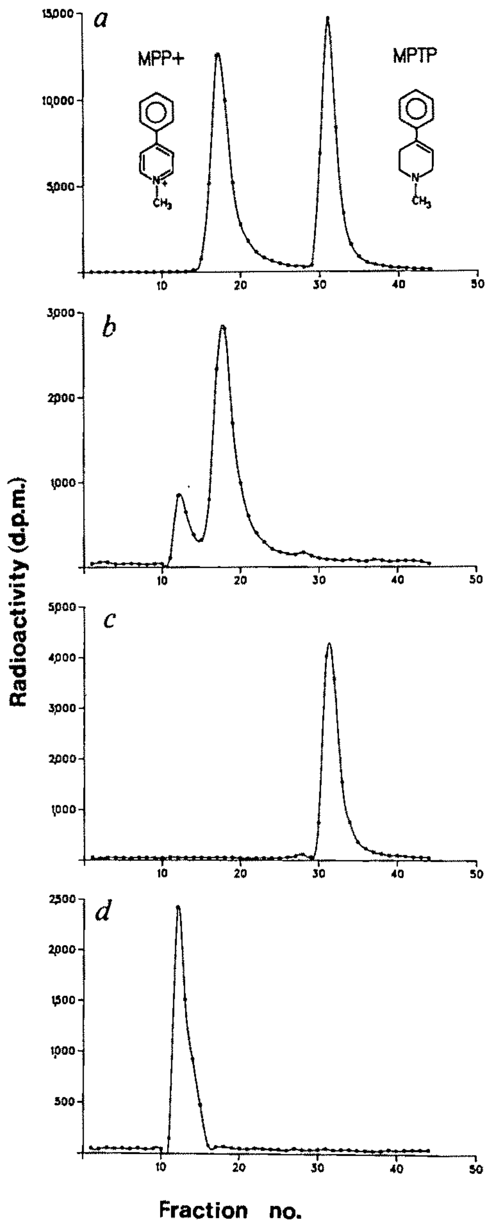

Fig. 1 *a*, Elution profiles of ^{3}H-MPTP and ^{14}C-MPP$^+$. *b*, Elution profile of radioactivity extracted from the brain of monkey BZ9. The predominant ^{3}H peak extracted from the monkey brain co-eluted with MPP$^+$ (fractions 16–24). The elution profile in *c* is that of hexane-extractable ^{3}H-labelled material obtained after $NaBH_4$ reduction of 50 μl of an ethanol extract. This reduced compound eluted as a single peak coincident with MPTP. The radiochromatogram in *d* is for cerebrospinal fluid from monkey BZ9 taken at the time of killing. The absence in CSF of MPP$^+$, which predominates in brain, is indicative of the intraneuronal trapping of MPP$^+$.

Methods: Monkey BZ9 was injected with $^3H_2$-MPTP and killed 24 h later. The left half of the brain was regionally dissected and homogenates were prepared as described in the text. An extract containing the radioactivity was prepared by adding an equal volume of ethanol to a small aliquot (0.5 ml) of an aqueous homogenate, vortexing thoroughly, then centrifuging at 16,000*g* for 15 min. Samples (50 μl) of a representative extract were then injected into an HPLC system consisting of a 5 μ, 25 cm, C-18 reverse-phase column with a mobile phase of acetonitrile/100 mM sodium acetate (60:40, v/v) containing 0.1% triethylamine (final *p*H 5.6) at a flow rate of 1.0 ml min^{-1}; 44 fractions were collected at 15-s intervals and counted in 10 ml Aquasol (NEN) at an efficiency of 46%. Recovery of injected radioactivity was 100%, in all cases.

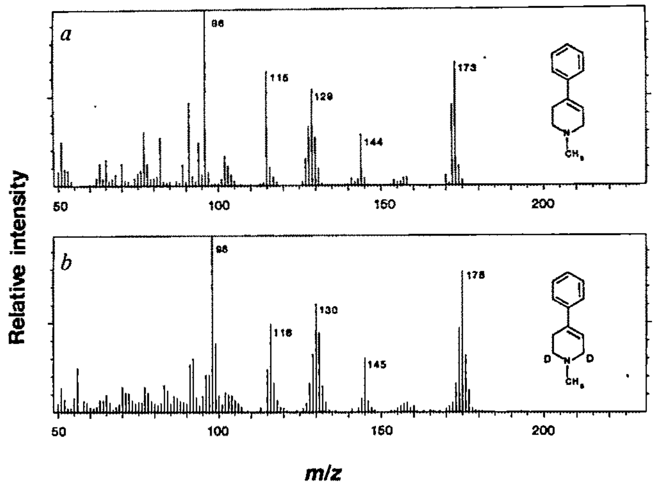

Fig. 2 *a*, Mass spectrum of authentic MPTP. *b*, Mass spectrum of metabolite reduced with NaB^2H_4 which was extracted from brain tissue of a monkey treated with MPTP.

Methods: One-half of the brain of a rhesus monkey (tissue weight 39.1 g) which died 17 days after the last of five daily injections of MPTP (0.33 mg per kg per day, total dose 9.6 mg) was homogenized in 5 vol. water. This homogenate was extracted with an equal volume of ethanol and the protein precipitated by centrifugation at 23,000*g* for 20 min. The supernatant was washed three times with 2 vol. hexane, then reacted with 1.78 g of NaB^2H_4 at room temperature for 30 min. The resulting product was extracted into hexane (two extractions with equal volumes of hexane), then concentrated to a volume of 5 ml by a series of forward and backward extractions of decreasing volume. A small quantity of decane (40 µl) was added to the final 5 ml of hexane, which was then evaporated to 40 µl under a gentle stream of N_2. This solution (0.5 µl) was inected into a 30 m × 0.322 mm DB-1 fused silica gas chromatographic column directly coupled to the ion source of a Finnigan 3200 quadrupole mass analyser.

(10 mg per kg); after 1 h both groups of mice were injected i.p. with MPTP (10 mg per kg) and 7.7 µCi [1-^{14}C]MPTP. Pairs of mice (control and pargyline-pretreated) were killed by spinal dislocation 5, 10, 20, 30, 40, 60, 120 and 240 min after the latter injection. The brains were rapidly removed, frozen on dry ice, and stored at −20 °C until extracted and assayed by HPLC, as described in Fig. 3 legend. In a separate experiment, two groups of seven mice were treated as above, but injected with unlabelled MPTP alone, and killed 10 min later. The brains were removed and rapidly frozen, then stored until assayed by gas chromatography–mass spectrometry (GC–MS). Briefly, $^2H_5$- or $^2H_{10}$-internal standards were added to brain homogenates, basified, and MPTP extracted into toluene. Reducible metabolites were assayed as $^2H_2$-MPTP after reduction with sodium borodeuteride and toluene extraction. The organic extracts were derivatized with isobutyl chloroformate to form a stable derivative with excellent chromatographic properties, and assayed by determining the ratio of ions from unlabelled MPTP ($m/z = 202$), reducible metabolites ($m/z = 204$), and internal standards ($m/z = 206$ or 210).

The persistence of large amounts of radioactivity in the rhesus monkey brains was apparent from the percentages of administered radioactivity found in each brain (Table 1). In the case of monkey BZ9, 0.99% of the total injected dose was recovered from the brain after 24 h, whereas ~0.2% still remained after 20 days in monkey 28. From a log plot of the ^3H data from four monkeys, a terminal-phase half life of 10 days was estimated. Virtually all of the radioactive material present in the monkey brains was ethanol-extractable from an aqueous tissue homogenate (98–99%). Measurements in 16 dissected brain regions from each monkey indicated that the pattern of radioactivity observed in the monkey brain at 24 h was consistent for at least 20 days. Furthermore, the use of a toxic dose did not affect the pattern observed with a tracer dose (for example, monkey BZ9 versus monkey 678).

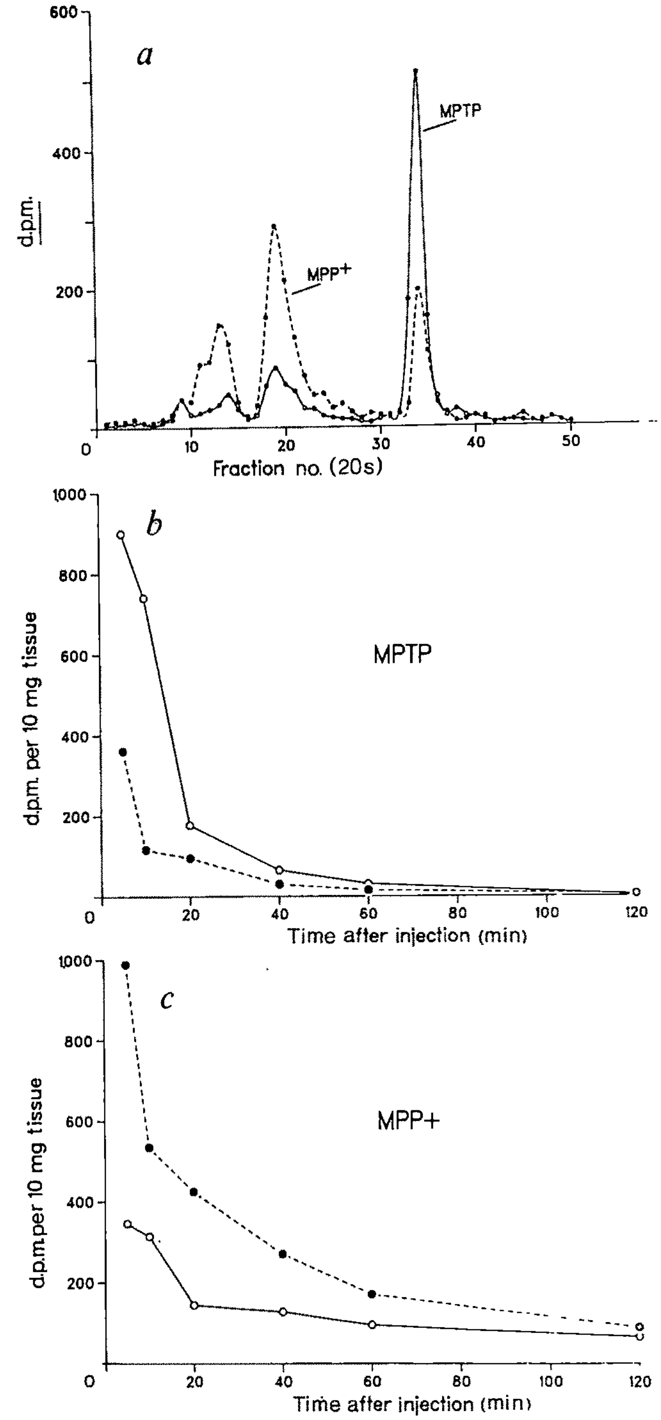

Fig. 3 Effect of pargyline pretreatment on MPTP metabolism in mice. ---●---, Control mice; —○—, pargyline-pretreated. The total radioactivity contained in the MPTP peak and MPP$^+$ peak (*a*) was summed for each mouse brain extract and the totals plotted against the time after injection (*b* and *c*). Pargyline pretreatment increased the levels of MPTP at all times, while blocking the enzymatic conversion to MPP$^+$.

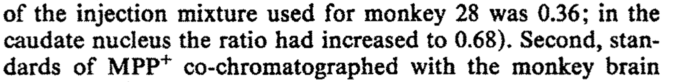
Methods: Fourteen adult male mice (NIH Swiss Webster, 20–22 g) were used in this experiment. Half were injected i.p. with 0.2 ml saline and half with 10 mg per kg pargyline in 0.2 ml saline; after 1 h all animals were injected i.p. with 0.2 ml of a saline solution containing 0.2 mg MPTP (10 mg per kg) and 7.7 µCi ^{14}C-labelled MPTP. Pairs of mice (control and pargyline-pretreated) were killed by spinal dislocation 5, 10, 20, 40, 60, 120 and 240 min after the latter injection. The brains were rapidly removed, frozen on dry ice, and stored at −20 °C until used. Frozen brains were weighed, then homogenized in 4 vol. distilled water. A 0.5-ml aliquot of each homogenate was added to an equal volume of ethanol, vortexed, then centrifuged at 14,000*g* for 10 min. The radioactive components in the supernatant were separated by HPLC as described for Fig. 1.

Table 1 Amounts of radioactivity injected and survival times for four monkeys used in the study

Monkey	BZ9	910E	28	678
Weight (kg)	6.85	7.25	6.15	6.70
Dose of $^3H_2$-MPTP (mCi per animal)	9.3	1.15	1.15	0.75
Dose of ^{14}C-MPTP (mCi per animal)	–	0.41	0.41	0.49
Total MPTP dose (mg per kg)	Trace	0.19	0.22	0.90
Survival time after injection (days)	1	10	20	5/10*
% Of injected ^3H in brain	0.99	0.32	0.18	0.47
% Of injected ^{14}C in brain	–	0.40	0.22	0.24

* $^3H_2$-MPTP was injected 5 days after ^{14}C-MPTP. Total survival time was 10 days.

Figure 1*b* shows the HPLC analysis of a brain extract taken 24 h after a single injection of $^3H_2$-MPTP (monkey BZ9). The elution profile remained constant regardless of either the brain region examined or the time since injection of MPTP. The major MPTP metabolite, which eluted as a single peak somewhat more polar than MPTP, always accounted for ~80% of the total radioactivity. To isolate and identify this metabolite, we considered expected routes of MPTP metabolism including *N*-demethylation, ring hydroxylation and protein alkylation[7]. The solubility properties of the monkey brain metabolite precluded protein alkylation. HPLC comparison of authentic *N*-dealkylated or 4-phenylhydroxylated standards indicated that the monkey brain metabolite is intermediate in polarity. We then considered the pyridinium oxidation product of MPTP, 1-methyl-4-phenylpyridine (MPP$^+$)(shown below).



Several lines of evidence have confirmed the presence of MPP$^+$ in the brains of monkeys treated with MPTP. First, formation of this product would require partial loss of ^3H from [2,6-$^3H_2$]MPTP, but would preserve the 1-^{14}C label, causing an increased ^{14}C:^3H ratio. We observed this in monkeys which had received double-labelled MPTP (for example, the ^{14}C:^3H ratio of the injection mixture used for monkey 28 was 0.36; in the caudate nucleus the ratio had increased to 0.68). Second, standards of MPP$^+$ co-chromatographed with the monkey brain metabolite (Fig. 1*a*). Treatment of radiolabelled monkey brain extract with $NaBH_4$ quantitatively converted the metabolite into a hexane-extractable base which co-chromatographed with MPTP (Fig. 1*c*). Finally, sufficient metabolite to analyse by GC–MS was isolated (see Fig. 2 for details) from the brain tissue of a monkey which died 17 days after treatment with MPTP (1.65 mg per kg). Reduction of the metabolite with NaB^2H_4 yielded a product determined by mass spectrometry to be $^2H_2$-MPTP, the reduction product of the quaternary amine MPP$^+$ (Fig. 2). Thus, in monkey brain, MPTP is oxidized to MPP$^+$, which is retained in the brain for over 20 days.

Our experiments in mice provide evidence that the metabolism of MPTP is, in fact, required for the expression of neurotoxicity. Heikkila *et al.* have demonstrated that MPTP depletes neostriatal dopamine and destroys nerve cells in the zona compacta of the substantia nigra in mice[4]. This neurotoxicity can be blocked with monoamine oxidase (MAO) inhibitors including pargyline (see accompanying paper[5]). We found that pargyline decreased the oxidation of MPTP with a resultant increase in brain levels of MPTP and decreased concentrations of MPP$^+$ (Fig. 3). After 10 min, the ratio of MPTP to MPP$^+$ was 0.2 and 2.4 in the saline-pretreated and the pargyline-pretreated mouse brain, respectively, indicating the effectiveness of metabolic blockade. This observation was quantified in two groups of mice killed 10 min after injection with MPTP (10 mg per kg i.p.). Assay of MPTP and MPP$^+$ indicated higher levels of MPTP in the brains of pargyline-pretreated mice than in saline controls (188 ± 27 as opposed to 67 ± 13 ng per mg tissue ±s.e.m.; $P<0.01$ using Student's *t*-test). Conversely, the MPP$^+$ levels were significantly lower in the brains of pargyline-pretreated than in saline-pretreated mice (63 ± 8 compared with 144 ± 17 ng per mg tissue; $P<0.01$). Thus, pargyline blocks the oxidation of MPTP, but does not impair its entry to the brain. The fact that higher concentrations of MPTP were found at all times in the brains of pargyline-pretreated animals (Fig. 3*b, c*) indicates that MPTP cannot induce neurotoxicity without biotransformation. At times greater than 2 h, neither MPTP nor MPP$^+$ was present in appreciable amounts in the mouse brain, in marked contrast to the persistence of MPP$^+$ in the monkey brain. This difference in the persistence of MPP$^+$ may account for the difference in dose required to produce neurotoxicity in the mouse compared with the monkey (10 daily injections of 30 mg per kg produce only 80% neostriatal dopamine depletion in the mouse[4] whereas in

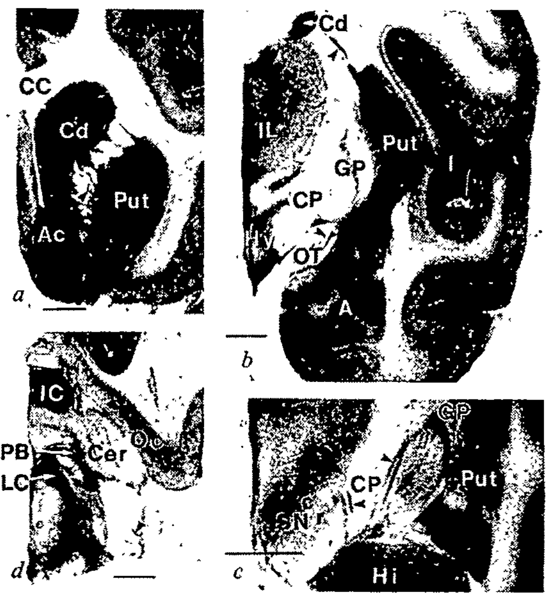


Fig. 4 Silver grain autoradiographic images of the brain of a monkey 24 h after treatment with $^3H_2$-MPTP. Cryostat-cut brain sections (30 μm) from monkey BZ9 were thaw-mounted onto slides, dried quickly at 60 °C and apposed to ^3H-sensitive film (3H-Ultrofilm, LKB) for 5 weeks. After developing, the sections were counterstained with Thionine (not shown) to allow comparison of morphology with autoradiographic localization patterns. The films show that the walls of arteries accumulate the label densely (arrowheads indicate examples), white matter and the globus pallidus (GP)(*b*) very little, and other grey matter structures by varying amounts. Computer-assisted densitometry confirmed the relative radioactive densities derived from liquid scintillation counting of digests or extracts of dissected brain regions, and added further details. Densest labelling occurred in the locus coeruleus (LC) and lateral parabrachial nucleus (PB)(*d*); within the thalamus the intralaminar nuclei (IL)(*b*) were selectively dense; the entire neostriatum, including the n. accumbens (Ac), was moderately dense (*a*); the cerebral cortex showed lower and rather invariant levels of density; the substantia nigra had still lower density—the substantia nigra reticulata as low as the GP (*c*). A, amygdala; CC, corpus callosum; Cd, caudate; Cer, cerebellum; CP, cerebral peduncle; Hi, hippocampus; Hy, hypothalamus; I, insular cortex; IC, inferior colliculus; Oc, occipital cortex; OT, optic tract; Put, putamen; SN, substantia nigra (c, compacta; r, reticulata). Scale bar, 3 mm.

the monkey, five daily injections of 0.33 mg per kg result in a 97% depletion[3]).

Oxidation of MPTP to MPP^+ in the primate provides a facile intracellular trapping mechanism similar to that proposed by Bodor *et al.* for site-specific drug delivery of dihydropyridines[8]. Evidence for the intracellular trapping mechanism comes from several observations. First, the radioactivity in the monkey brain was not uniformly distributed, but correlated with cytoarchitecture as illustrated by autoradiographic images of the brain from monkey BZ9 (Fig. 4). High concentrations of radioactivity were observed in the caudate nucleus, putamen, hypothalamus, nucleus accumbens (n. accumbens) and the parabrachial nuclei, while low levels were seen in white matter (for example, corpus callosum) and globus pallidus. Second, the radioactivity in cerebrospinal fluid (CSF) taken from the $^3H_2$-MPTP-treated monkey (BZ9) at the time of killing was lower than in any brain tissue, and the HPLC profile showed a total absence of MPP^+ (Fig. 1*d*). Finally, the MPP^+ persisting in all of the treated monkeys was easily extracted into water on homogenization and remained in solution after protein precipitation, indicating trapping as opposed to covalent binding to intracellular proteins.

In the monkey, the localization of high concentrations of MPP^+ in non-lesioned brain regions (for example, n. accumbens) suggests that the generation of MPP^+ does not ensure cell death[9]. The properties of nigrostriatal dopamine neurones which render them more sensitive to the toxic effects of MPTP are unknown, but the selectivity may be dose- and time-dependent. Burns *et al.*[3] clearly demonstrated temporary alterations in serotonergic and noradrenergic function following MPTP injection in the monkey.

We have demonstrated that MPP^+ is formed from MPTP in both monkey and mouse brain. This process is necessary for the expression of neurotoxicity in the mouse as evidenced by decreased metabolic formation of MPP^+ and increased MPTP concentrations in the brain in conditions which inhibit neurotoxicity. Whether MPP^+ is a selective toxin or the oxidation process forming MPP^+ is neurotoxic is unknown. The former notion is supported by the fact that MPP^+ was previously developed as a selective herbicide (Cyperquat, Gulf Oil Company), although never marketed; it has been reported to have animal toxicity (50% lethal dose in rat, 35 mg per kg, oral)[10]. Alternatively, the dehydrogenation of MPTP may produce toxic intermediates (for example, free radicals, dihydropyridines, *N*-oxides, hydrogen peroxide) within nigrostriatal neurones, a mechanism proposed for other neurotoxins and for Parkinson's disease[11]; this alternative is supported by the clinical observation that inhibition of monamine oxidase by deprenyl prolongs the life of patients with idiopathic Parkinson's disease by slowing the disease process[12]. Thus, there may be neurotoxic events common to both MPTP toxicity and Parkinson's disease. Regardless of whether it is the process or the product that is important, the study of the cellular consequence of the metabolic conversion of MPTP to MPP^+ appears relevant to our understanding of the pathogenesis of Parkinson's disease.

We acknowledge helpful discussions with Drs I. J. Kopin and D. M. Jacobowitz, the collaboration of Drs N. Castagnoli and R. E. Heikkila, and the technical assistance of C. Markey, M. Shih and R. Sherman.

Protection against the dopaminergic neurotoxicity of 1-methyl-4-phenyl-1,2,5,6-tetrahydropyridine by monoamine oxidase inhibitors

Richard E. Heikkila, Lawrence Manzino, Felicitas S. Cabbat & Roger C. Duvoisin

Department of Neurology, University of Medicine and
Dentistry of New Jersey-Rutgers Medical School, Piscataway,
New Jersey 08854, USA

1-Methyl-4-phenyl-1,2,5,6-tetrahydropyridine (MPTP) causes degeneration of the dopaminergic nigrostriatal pathway in several animal species, including humans[1,2], monkeys[3,4] and mice[5–7]. Changes observed after MPTP administration include marked decrements in the neostriatal content of dopamine and its major metabolites, dihydroxyphenylacetic acid and homovanillic acid, and a greatly diminished capacity of neostriatal synaptosomes to take up ^{3}H-dopamine[5,6]. In contrast, there is no pronounced loss of serotonin in the neostriatum or of dopamine and its metabolites in other brain areas in MPTP-treated animals. The oxidative metabolism of MPTP to 1-methyl-4-phenyl pyridine, a positively charged species, has been suggested as a critical feature in the neurotoxic process[8]. Moreover, in rat brain preparations, the monoamine oxidase (MAO) inhibitor pargyline and the specific MAO-B inhibitor deprenil can prevent the formation of 1-methyl-4-phenyl-pyridine from MPTP, while the specific MAO-A inhibitor clorgyline has no such effect[9], suggesting that MAO, and specifically MAO-B, is responsible for the oxidative metabolism of MPTP. We now report that pargyline, nialamide and tranylcypromine, which inhibit both MAO-A and MAO-B, when administered to mice before MPTP, protect against MPTP-induced dopaminergic neurotoxicity. Deprenil is also protective, but clorgyline is not. Our data are consistent with the premise that MAO-B has a crucial role in MPTP-induced degeneration of the nigrostriatal dopaminergic neuronal pathway.

Male, Swiss-Webster mice weighing 25–35 g were injected intraperitoneally with pargyline, deprenil, clorgyline, tranylcypromine or nialamide and subsequently received MPTP.

As Table 1 shows, 3 days after the last of five injections of MPTP, 30 mg per kg, the mean neostriatal content of dopamine (2.4 μg per g) fell markedly compared with the mean control value (10.7 μg per g). Animals given pargyline or nialamide alone had dopamine levels somewhat higher than control values, while the neostriatal dopamine content in mice receiving pargyline or nialamide before MPTP was similar to that in mice receiving the MAO inhibitors alone. The differences in dopamine levels between mice receiving MPTP alone and those receiving the MAO inhibitors plus MPTP were highly significant ($P < 0.001$). Thus, MPTP was non-toxic in the mice pretreated with either pargyline or nialamide. Similar results were obtained in mice killed 7 days after the last MPTP injection.

MPTP administration to mice also caused a pronounced decrement in the neostriatal content of the major metabolites of dopamine—dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA)—which was evident at both 3 and 7 days after the last MPTP injection, as has previously been reported[5–7]. This effect was probably due to the neurotoxic effects of MPTP. Mice treated with pargyline or nialamide, alone or before MPTP, also showed marked reductions in neostriatal levels of DOPAC and HVA. This latter effect was probably due to the residual inhibition of MAO by pargyline and nialamide, both of which are known to cause a long-lasting and irreversible inhibition of MAO. DOPAC and HVA are both formed from the enzymatic actions of MAO on the ethylamine side chain of dopamine and their levels should thus be diminished as long as MAO activity is decreased[10]. Any protective effect of pargyline

Table 1 The effects of pargyline or nialamide pretreatment on the MPTP-induced effects in mouse brain

MAOI	Treatment	Assay time (days)	*n*	Dopamine	DOPAC (μg per g tissue)	HVA	^{3}H-dopamine uptake (fmol per mg tissue)	% Of control
—	—	—	8	10.7 ± 1.2	4.7 ± 0.9	2.3 ± 0.5	814 ± 227	100

Parameters studied were levels of dopamine and its metabolites in mouse neostriatum and the capacity of a mouse synaptosomal preparation to accumulate ^{3}H-dopamine. The mice were treated with 15 mg per kg of pargyline or nialamide and subsequently given intraperitoneal injections of MPTP, 30 mg per kg (0.17 mmol per kg), dissolved in distilled water with the *p*H adjusted to 8.5 by dilute hydrochloric acid. Other mice received the MAO inhibitor alone, MPTP alone or no injections. Injection volumes were 1.0 ml per 100 g body weight. Levels of dopamine, serotonin and their metabolites were assayed in the neostriatum at various times after the last injection. The mice were stunned by a blow to the head, the brains removed and the neostriata rapidly dissected out. The paired neostriata were then weighed and homogenized in 0.3 M sucrose. An aliquot of this homogenate was diluted with an equal volume of 0.2 M perchloric acid containing dihydroxybenzylamine as an internal standard. The samples were centrifuged at 27,000*g* for 15 min and the supernatant used for assays[11]. A Bioanalytical Systems LC-304T liquid chromatograph connected to a Kipp and Zonen dual pen recorder was used for the assays. The operating potential was 750 mV, the temperature 25 °C; full scale on the detector was usually set to 1.0 nA. A Biophase ODS 5 μm column (Bioanalytical Systems) was used for all separations, with a flow-rate for the mobile phase of 1.5 ml min^{-1}. The mobile phase was made up as follows: 35 ml of acetonitrile was added to 965 ml of 0.15 M monochloroacetate buffer at *p*H 3.0 containing 193 mg of sodium octyl sulphate. This mixture was filtered and degassed, tetrahydrofuran (18 ml) was carefully added, and the mobile phase capped until use. The samples were injected into the liquid chromatograph and data calculated from standard curves run the same day based on five or six data points in the same concentration range as that present in the tissue. Levels of dopamine and its major metabolites DOPAC and HVA, and serotonin and its major metabolite 5-hydroxyindoleacetic acid were calculated on the basis of the original tissue weight and the results expressed in μg per g of tissue ± s.d. In some experiments, in the remaining 0.3 M sucrose homogenate, a synaptosomal preparation was made and the uptake of 2 nM ^{3}H-dopamine (30.2 Ci mmol^{-1}, NEN) was measured as described previously[12]. All data were calculated as fmoles of ^{3}H-dopamine accumulated per mg of tissue used ± s.d. and the data expressed as a per cent of control. Statistical analyses were done using Student's *t*-test.

or nialamide against MPTP, based on metabolic profiles, would therefore be masked by their capacity to inhibit MAO. These data indicate that decrements in levels of dopamine metabolites cannot by themselves always serve as a marker for determining whether toxicity to dopaminergic systems has occurred.

Table 1 also shows that neostriatal synaptosomes prepared from MPTP-treated mice had a greatly diminished capacity to take up ^{3}H-dopamine compared with control preparations. This observed decrement was the same (56%) at both 3 and 7 days after the last MPTP injection, indicating clearly that there was no recovery in MPTP-treated mice during this time[6,7]. In contrast to this marked decrement in ^{3}H-dopamine uptake, the ^{3}H-dopamine uptake in neostriatal synaptosomal preparations from mice pretreated with pargyline or nialamide before MPTP was relatively close to or only slightly below control values (Table 1), as was ^{3}H-dopamine uptake in mice treated with pargyline or nialamide alone. The difference in ^{3}H-dopamine uptake between mice receiving MPTP alone and those receiving the MAO inhibitors plus MPTP were significant (*P* values ranged from <0.05 to <0.001).

Six injections of MPTP produced a very large fall in the neostriatal content of dopamine, evident at both 5 and 12 days after the last MPTP injection (Table 2). The differences in neostriatal dopamine content between control and MPTP-treated animals were highly significant ($P < 0.001$). MPTP treatment also caused large decrements in the neostriatal content of DOPAC and HVA (Table 2). The MAO-B inhibitor deprenil was completely protective against the MPTP-induced dopaminergic neurotoxicity (Table 2). Levels of dopamine and its metabolites in animals receiving deprenil plus MPTP did not

Table 2 The effects of deprenil or clorgyline pretreatment on the MPTP-induced decrements in the neostriatal levels of dopamine and its metabolites

MAOI	Treatment	Assay time (days)	*n*	Dopamine	DOPAC (μg per g tissue)	HVA
—	—	—	7	11.7 ± 1.1	3.6 ± 1.0	2.7 ± 0.5
Deprenil	—	5	4	13.1 ± 2.4	3.0 ± 0.4	2.8 ± 0.7

Clorgyline	MPTP	5	5	4.9 ± 2.6	1.0 ± 0.3	1.0 ± 0.2
Deprenil	—	12	3	12.6 ± 1.0	2.9 ± 0.7	2.3 ± 0.5
Clorgyline	—	12	3	12.7 ± 1.4	2.5 ± 0.4	1.8 ± 0.1
—	MPTP	12	3	2.9 ± 0.8	1.4 ± 0.2	1.5 ± 0.4
Deprenil	MPTP	12	6	12.6 ± 1.3	2.3 ± 0.4	2.1 ± 0.3
Clorgyline	MPTP	12	3	4.6 ± 2.6	1.3 ± 0.2	1.4 ± 0.2

The mice were treated with the MAO-inhibitor at 10 mg per kg on days 1 and 8, and with 30 mg per kg of MPTP on days 1, 2, 3, 8, 9 and 10. On days 1 and 8, the MPTP was given 30 min after the MAO-inhibitor. The mice were then killed either 5 or 12 days after the last MPTP injection (on days 15 and 22, respectively). The data represent the mean value ±s.d.

differ significantly from levels in mice receiving deprenil alone ($P > 0.1$). However, in contrast to these protective effects of deprenil, the MAO-A inhibitor clorgyline, in identical conditions, failed to protect against MPTP-induced toxicity. Thus, dopamine levels were not significantly different in mice receiving MPTP alone and those given clorgyline plus MPTP ($P > 0.1$).

These data clearly demonstrate that two general MAO inhibitors, pargyline and nialamide (Table 1), and the specific MAO-B inhibitor deprenil (Table 2), effectively protect against the neostriatal dopaminergic neurotoxicity of MPTP in Swiss-Webster mice. We have obtained similar protective effects of these three MAO inhibitors against MPTP-induced toxicity in C57BL mice. In other experiments in Swiss-Webster mice, tranylcypromine, another inhibitor of both MAO-A and MAO-B, also protected against MPTP dopaminergic neurotoxicity. For example, neostriatal dopamine levels in mice receiving three MPTP injections of 30 mg per kg, with assays done 4 days after the last injection, were 4.4 ± 1.8 µg per g tissue ($n = 7$). In contrast, mice pretreated with 15 mg per kg of tranylcypromine 30 min before the MPTP injections had a neostriatal dopamine level of 13.3 ± 1.9 µg per g ($n = 6$). Neostriatal dopamine levels in control mice and in mice receiving only tranylcypromine were 12.3 ± 1.3 µg per g ($n = 8$) and 14.0 ± 0.4 µg per g ($n = 3$), respectively.

Our data are thus consistent with the premise that pargyline, nialamide, tranylcypromine and deprenil protect against the neurotoxic actions of MPTP by preventing the enzymatic formation of active metabolites of MPTP catalysed by MAO-B. However, it would be incautious to conclude that the prevention by these MAO inhibitors of the oxidative metabolism of MPTP is the sole mechanism for the observed protection. Nevertheless, the data have several important implications. First, they show that the mouse is an extremely useful small animal in which to study the mechanism of action of MPTP. Second, if the mouse data can be extrapolated to the monkey or human, a good working hypothesis would be that treatment with pargyline, nialamide, deprenil or other drugs capable of inhibiting MAO-B might counteract the neurotoxic actions of MPTP in the monkey or human. Third, and perhaps most important, if there is any relationship between the mechanism for the induction of MPTP-induced parkinsonism in experimental animals and Parkinson's disease in humans, investigators should be aware of a potential role for MAO in human parkinsonism.

We thank Drs S. P. Markey, N. Castagnoli, A. Trevor for many helpful discussions and also for sharing experimental observations before publication. This work was supported by a grant from the USPHS and by a gift from the United Parkinson Foundation.

Monoclonal antibodies against carbohydrate differentiation antigens identify subsets of primary sensory neurones

J. Dodd, D. Solter* & T. M. Jessell

Dorsal root ganglion (DRG) neurones transmit cutaneous sensory information from the periphery to the spinal cord. Within the dorsal horn of the spinal cord, classes of sensory fibres that are activated by different cutaneous stimuli terminate in separate and highly restricted laminae[1–3]. Although the developmental events resulting in the laminar organization of sensory afferent terminals have not been defined, it is likely that interactions between surface molecules on DRG and dorsal horn neurones are involved in the generation of afferent synaptic connections. The identification of surface antigens that distinguish functional subclasses of DRG neurones would represent a first step in establishing the existence and nature of such molecules. We report here that monoclonal antibodies directed against carbohydrate differentiation antigens[4,5] identify cytoplasmic and cell surface molecules expressed selectively by functional subsets of DRG neurones.

We used monoclonal antibodies to preimplantation murine embryos and human embryonal carcinoma cells, which recognize the developmentally-regulated stage-specific embryonic antigens, SSEA-3 and SSEA-4[6–8]. These antigens have been characterized as overlapping carbohydrate epitopes on globo-series glycolipids[8] (Table 1). Their presence in primary sensory neurones is demonstrated by indirect immunofluorescence on frozen or aldehyde-fixed sections of adult rat DRG and spinal cord. Incubation of DRG sections with anti-SSEA-3 or anti-SSEA-4 results in the labelling of neuronal cell bodies (Fig. 1*a*, *b*) and sensory axons within the DRG and dorsal roots (Fig. 1*a*–*d*), with no detectable staining of non-neuronal elements. Intense SSEA-3 and SSEA-4 immunoreactivity occurs within the cytoplasm of DRG neurones and in association with the neuronal plasma membrane. Anti-SSEA-3 labels 9% and anti-SSEA-4 labels 11% of all DRG neurones (Table 2*a*), the majority of these being of intermediate and large diameter (30–60 µm). The percentage of immunoreactive neurones is constant in the DRG at cervical, thoracic and lumbar levels and there is no obvious topographical organization of labelled neurones within the DRG. SSEA-3 and SSEA-4 epitopes are also expressed by subpopulations of neurones in cranial sensory ganglia (Table 3), and are detected in subpopulations of DRG neurones in the mouse, cat and squirrel monkey (data not shown). A more complete description of SSEA distribution in primary sensory neurones will be reported elsewhere.

To determine the relationship between SSEA-3$^+$ and SSEA-4$^+$ DRG neurones in the rat, we used subclass-specific second antibodies that distinguish anti-SSEA-3 (a rat IgM) from anti-SSEA-4 (a mouse IgG3) on single sections of the DRG. Most immunoreactive DRG neurones are SSEA-3$^+$/SSEA-4$^+$ (Fig. 1*f*, *g*; Table 2*a*); a few small-diameter neurones are, however, solely SSEA-3$^+$ and many large-diameter neurones are solely SSEA-4$^+$ (Table 2*a*). Double labelling has shown that SSEA-3$^+$, SSEA-3$^+$/SSEA-4$^+$ and SSEA-4$^+$ neurones are distinct from the DRG neurones that express the peptide transmitters substance P and somatostatin[9]. Sequential immunofluorescence and histochemical staining demonstrate that SSEA-3$^+$, SSEA-3$^+$/SSEA-4$^+$ and SSEA-4$^+$ neurones are also distinct from those that express the fluoride-resistant acid phosphatase isoenzyme (FRAP)[10,11].

Table 1 Stage-specific embryonic antigen carbohydrate structure

Antibody	Epitope	Immunogen	Ref.
Anti-SSEA-3	GalNAcβ1→3 Galα1→4Gal	4–8 cell stage murine embryos	7, 8
Anti-SSEA-4	NeuAcα2→3 Galβ1→3GalNAc	2102Ep teratocarcinoma	8

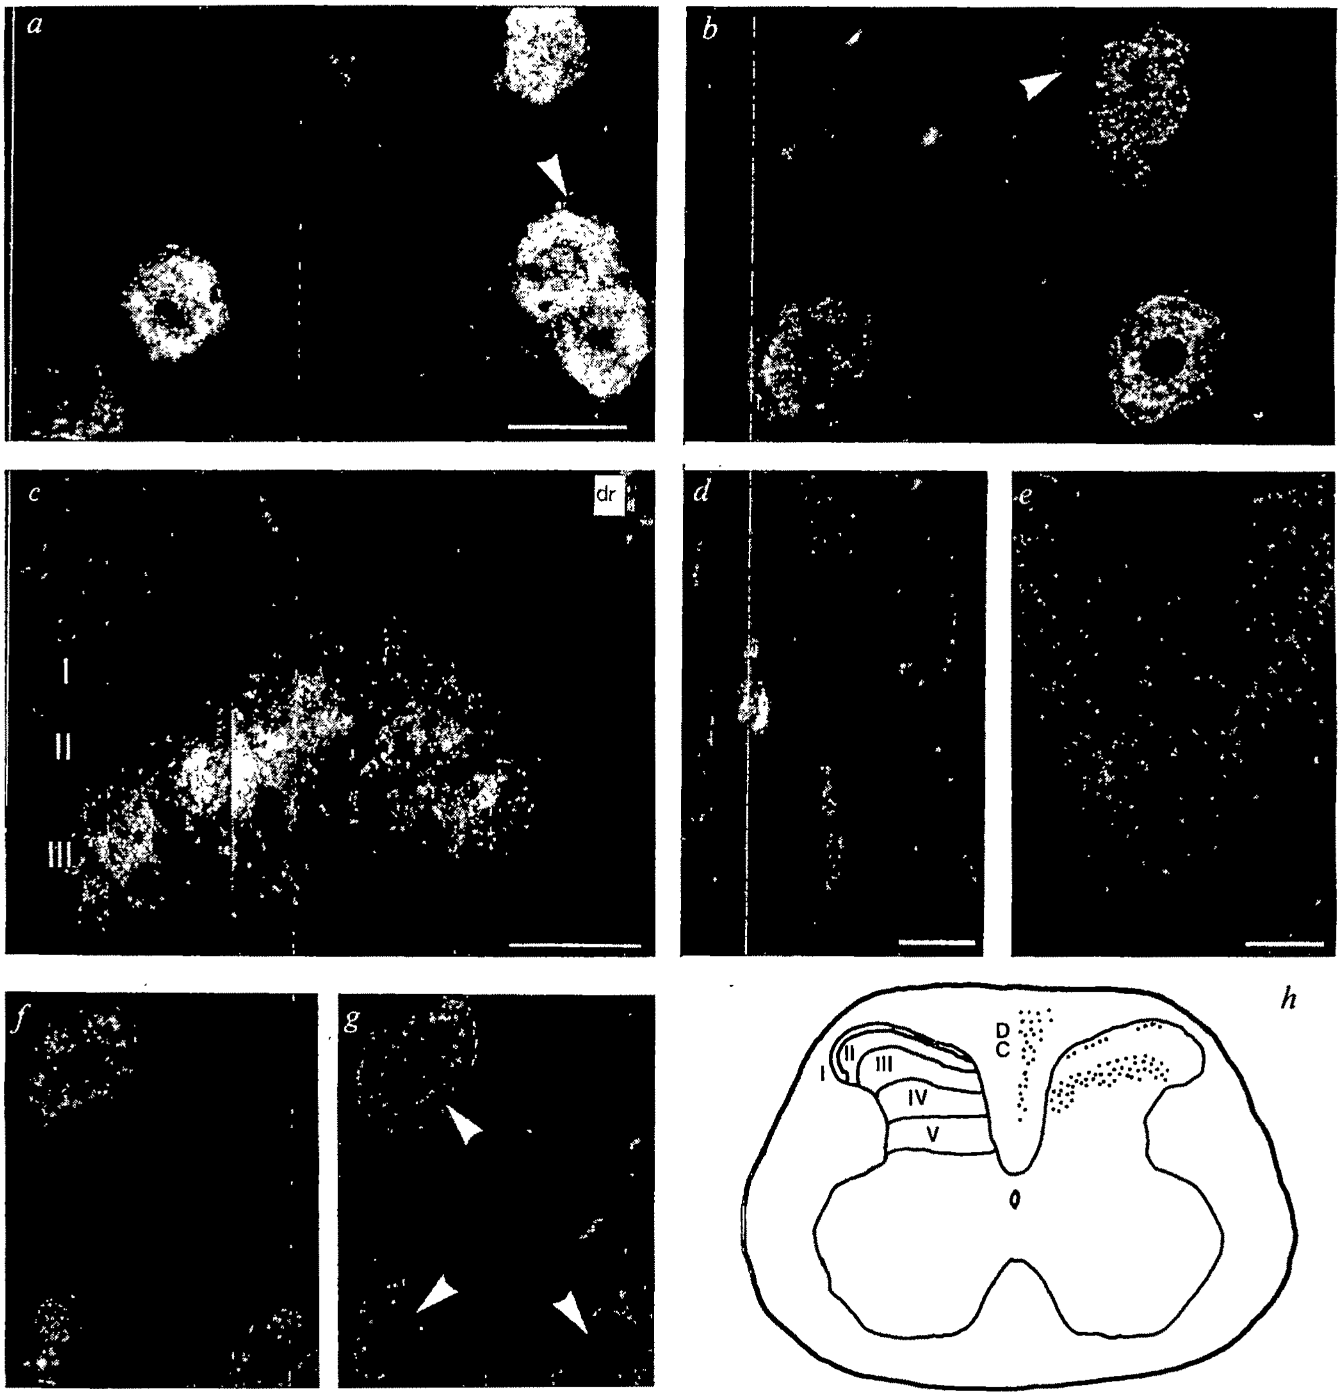

Fig. 1 Expression of SSEA epitopes by subpopulations of primary sensory neurones. Anti-SSEA-3 (*a*) and anti-SSEA-4 (*b*) produced bright, cytoplasmic labelling of a subpopulation of neurones in sections of DRG (arrows indicate stained axons). *c*, SSEA-4$^+$ fibres and terminals are found in a dense band in lamina III of the dorsal horn, with scattered fibres projecting into lamina IV. Immunoreactive afferent fibres can also be seen in cross-section, overlying the medial dorsal horn. In addition, SSEA-4$^+$ afferents are present in the dorsal root (dr) seen here in cross-section. In *c* and *h*, I, II, III, IV and V represent the location of the Rexed's laminae. *d*, SSEA-3$^+$ fibres are shown in a longitudinal section through a dorsal root. *e*, The distribution of SSEA-3$^+$ fibres in a transverse section through the dorsal columns. *f*, *g*, A single section of DRG was incubated with anti-SSEA-3 and anti-SSEA-4 and the distribution of the two antibodies was visualized using subclass-specific antibodies coupled to different fluorophores. *f*, Three DRG neurones that express SSEA-3; *g* shows the presence of SSEA-4 in the same neurones (arrows). Control experiments indicated that neither cross-reactivity of the antibodies nor barrier filter leakage contributed to this result. *h*, A diagram of a coronal section of the rat spinal cord, shows the laminar distribution of the central processes of SSEA-3$^+$ and SSEA-4$^+$ DRG neurones. SSEA-3$^+$ and SSEA-4$^+$ fibres were found predominantly in lamina III with a sparse representation in lamina I, a dense region of staining at the medial border of laminae III and IV and stained fibres in the cuneate and gracile fasciculi (DC). Scale bars: *a*, *b*, *f*, *g*, 40 μm; *c*, 80 μm; *d*, 10 μm; *e*, 150 μm.

Methods: Rat tissues were fixed by cardiac perfusion with 50 ml ice-cold saline followed by 500 ml ice-cold 4% paraformaldehyde in 0.1 M phosphate buffer, *p*H 7.2. Cryostat sections (10 μm) were incubated with anti-SSEA ascites fluid, diluted 1:100 to 1:300 in phosphate-buffered saline (PBS: 0.1 M PB in 0.9% saline) containing 10% fetal calf serum and 0.2% Triton X-100, *p*H 7.2 (16 h; 4 °C). *a–e*, Sections were washed with PBS containing 2% normal goat serum (PBS/NGS), incubated with fluorescein isothiocyanate (FITC) goat anti-mouse IgM or IgG (Tago, Inc. and Boehringer-Mannheim, respectively) diluted 1:75 in PBS/NGS for 30 min at room temperature. Sections were then washed in PBS/NGS and coverslipped in 50% glycerol in 0.1 M sodium carbonate buffer, *p*H 9.0, containing 0.4 mg ml^{-1} *p*-phenylenediamine (Sigma). *f*, *g*, Following incubation with anti-SSEA, sections were washed in PBS/NGS and incubated in PBS/NGS containing FITC-goat anti-mouse IgM, 1:75 and unconjugated rabbit anti-mouse IgG3, 1:30 (Litton Bionetics), for 30 min at room temperature. Sections were then washed again in PBS/NGS and incubated with FITC-goat anti-mouse IgM, 1:75 plus rhodamine-goat anti-rabbit IgG, 1:200 (Tago), for 30 min at room temperature. Sections were then washed and coverslipped as described above.

Table 2 Expression of SSEAs by rat DRG neurones

a, Cytoplasmic staining in adult rat DRG neurones *in situ*

Antigen	% Immunoreactive neurones	% Overlap
SSEA-3	9 ($n = 7868$)	68 SSEA-4$^+$
SSEA-4	11 ($n = 4789$)	55 SSEA-3$^+$

b, Surface staining of DRG neurones in culture

Antigen	% Immunoreactive neurones	% Overlap
SSEA-3	7 ($n = 1060$)	84 SSEA-4$^+$
SSEA-4	14 ($n = 1775$)	40 SSEA-3$^+$

Table 3 Expression of SSEAs in primary sensory neurones

	% SSEA-3	% SSEA-4
Dorsal root ganglion	9	11
Trigeminal ganglion	20	35
Petrosal ganglion	15	15
Jugular ganglion	<5	10
Nodose ganglion	60	>90

The distribution of molecules bearing the SSEA-3 and SSEA-4 epitopes in the central nervous system was examined by indirect immunofluorescence on 10 μm coronal sections taken at 100 μm intervals from the caudal brain stem to the olfactory bulb. We do not find SSEA-3$^+$ or SSEA-4$^+$ neuronal cell bodies within the CNS. In the spinal cord and brain stem, SSEA-3$^+$ and SSEA-4$^+$ immunoreactive fibres and terminals are restricted to regions that receive primary afferent input. In the dorsal horn of the spinal cord, a few labelled fibres and terminals are found in lamina I (Fig. 1*h*), whereas the tract of Lissauer and lamina II are devoid of immunoreactive fibres (Fig. 1*c*, *h*). The greatest density of labelled fibres occurs in lamina III (Fig. 1*c*) and the medial region of lamina IV (Fig. 1*h*). SSEA-3$^+$ and SSEA-4$^+$ fibres are also present in the dorsal columns (Fig. 1*e*) and in the gracile and the external cuneate nuclei. No immunoreactive fibres are observed on the lesioned side of the spinal cord in animals unilaterally deafferented 3 weeks previously by section of the dorsal roots. These results indicate that all SSEA-3$^+$ and SSEA-4$^+$ fibres within the dorsal horn of the spinal cord derive from sensory neurones within DRG.

The precise laminar arrangement of the central terminals of cutaneous afferent fibres in the rat has not been mapped in detail. The laminar cytoarchitecture and the distribution of peptide-containing sensory terminals in the rat dorsal horn are, however, similar to those in cat and primate[12,13], and we have found the laminar distribution of SSEA-3$^+$ and SSEA-4$^+$ that fibres in the dorsal horn is similar in rat, cat and squirrel monkey (J.D., T.M.J. and E. R. Perl, unpublished observations). In cats and primates, the terminal arbors of several classes of low threshold afferents are known to overlap within laminae III and IV[1]. Our observations are therefore consistent with the presence of SSEA-3 and SSEA-4 epitopes on low-threshold hair follicle afferents and mechanoreceptors[14,15]. The absence of labelled terminals in lamina II indicates that unmyelinated primary afferents do not express the SSEA-3 and SSEA-4 epitopes.

The SSEA-3 and SSEA-4 carbohydrate sequences are also expressed on the surface of DRG neurones. Approximately 7% of neonatal rat DRG neurones maintained in dissociated cell culture exhibit SSEA-3 immunoreactivity on neuronal somata and processes (Fig. 2*a*, *b*; Table 2*b*), and the SSEA-4 epitope is present on 14% of cultured DRG neurones (Fig. 2*c*, *d*; Table 2*b*). Dual-colour labelling with subclass-specific second antibodies reveals that the relationship between SSEA-3 and SSEA-4 epitopes on the surface of cultured DRG neurones is similar to that observed in the cytoplasm of DRG neurones *in situ*: over 80% of SSEA-3$^+$ DRG neurones in culture are SSEA-4$^+$ and, conversely, 40% of SSEA-4$^+$ neurones are SSEA-3$^+$ (Table 2*b*). SSEA-3$^+$ and SSEA-4$^+$ DRG neurones may correspond to the population of cultured sensory neurones that are labelled with antiserum to the globo-series glycolipid, globoside[16].

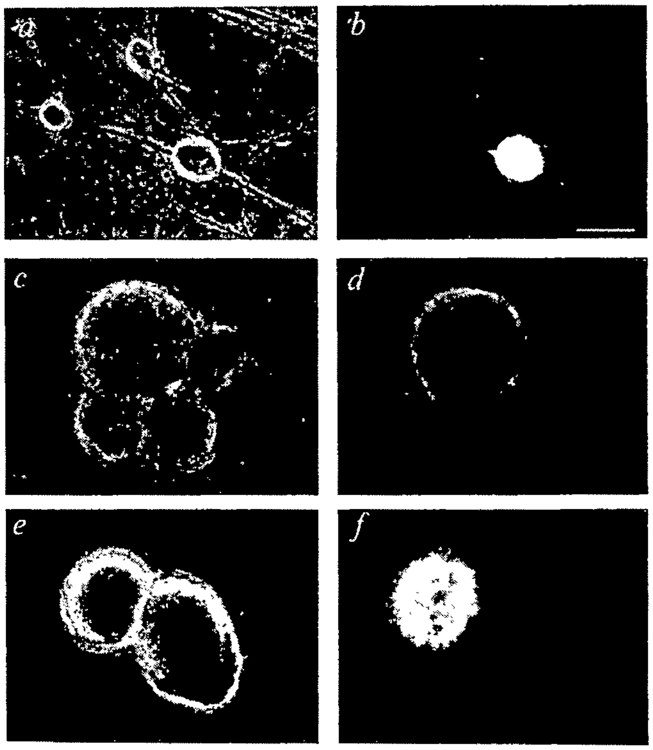

Fig. 2 Expression of SSEA epitopes on the surface of cultured DRG neurones. *a*, Phase micrograph showing three DRG neurones and a plexus of neuronal processes. *b*, Fluorescence micrograph of the field shown in *a*: one of the three neurones expresses intense SSEA-3 immunoreactivity on its cell soma and processes. *c*, Phase-contrast micrograph showing four DRG neurones. *d*, Fluorescence micrograph of the field shown in *c*; one of the neurones expresses SSEA-4 immunoreactivity. *e*, Phase-contrast micrograph of two adult rat DRG neurones. *f*, Immunofluorescent micrograph of the field shown in *e*, in which only one neurone expresses intense SSEA-3 immunoreactivity. Scale bar: *a*, *b*, 30 μm; *c*, *d*, 20 μm; *e*, *f*, 20 μm.

Methods: DRG neurones were isolated from neonatal rats and maintained in dissociated cell culture for periods of 14–42 days using previously described methods[26]. Non-neuronal cells were eliminated from DRG cultures by treatment with cytosine arabinoside (10 μM) for 24–48 h soon after plating. Live cultures were washed in HEPES-buffered balanced salt solution (BSS) supplemented with glucose and 0.1% bovine serum albumin. Cultures were then incubated with anti-SSEA ascites fluid diluted 1 : 100 to 1 : 200 in buffered BSS containing 1% NGS. FITC-labelled second antibodies were diluted in buffered BSS and used as described in the legend to Fig. 1.

We excluded the possibility that the cell surface expression of SSEA-3 and SSEA-4 epitopes is a result of maintaining DRG neurones in culture, by labelling adult rat DRG neurones immediately after dissociation. Many of these neurones are also SSEA-3$^+$ and SSEA-4$^+$ (Fig. 2*e*, *f*), but the low cell yields obtained after mechanical dissociation of adult DRG neurones preclude determination of the percentage of labelled cells.

The SSEA-3 and SSEA-4 epitopes are associated with glycolipids and glycoproteins on murine embryos and human embryonal carcinoma cells[6,8]. SSEA-3 and SSEA-4 immunoreactivity in fixed sections of DRG and spinal cord is abolished by chloroform–methanol treatment (1 : 1, 15 min) whereas peptide and protein antigens, recognized by other monoclonal antibodies, are not affected by identical treatment. Moreover, preincubation of sections with 10 mM sodium periodate for 30 min at room temperature, substantially reduced SSEA-3 and SSEA-4 immunoreactivity. These observations suggest that in sensory neurones, both epitopes are associated, at least in part, with glycolipids.

Our results suggest that subpopulations of DRG neurones involved in the processing of low threshold cutaneous stimuli can be identified by the surface expression of globo-series carbohydrates. In preliminary experiments, we have detected the SSEA-3 and SSEA-4 epitopes on some DRG neurones in 16-day rat embryos, soon after final mitosis[17]. Therefore, anti-SSEA antibodies may provide specific probes to examine early development and differentiation of this class of DRG neurones. Several other monoclonal antibodies have recently been generated against carbohydrate sequences expressed on the surface of embryonic or transformed cells[18,19]. We have found that some of these carbohydrate determinants are expressed selectively on subsets of DRG neurones distinct from those that express SSEA-3 and SSEA-4 epitopes[20], suggesting that many subclasses of DRG neurones may be characterized by differences in cell surface carbohydrate expression.

Cell surface carbohydrates have been implicated in intercellular adhesion and recognition in early embryos and embryonal carcinoma cells[21–23], and in neuronal adhesion during embryonic development[24,25]. Molecules bearing SSEA-3, SSEA-4 and other carbohydrate determinants could therefore be involved in the development and specification of sensory connections in the dorsal horn of the spinal cord.

Pattern of presynaptic nerve activity can determine the type of neurotransmitter regulating a postsynaptic event

Nancy Y. Ip & Richard E. Zigmond*

Department of Pharmacology, Harvard Medical School, Boston,
Massachusetts 02115, USA

The mammalian superior cervical ganglion has been the classical preparation for studying cholinergic transmission between neurones[1–3]. Recently, however, evidence has been presented showing that, in addition to the postsynaptic changes mediated via nicotinic and muscarinic receptors, there is a non-cholinergic component to transmission in this ganglion[4,5], as in frog paravertebral ganglia[6,7]. In the rabbit superior cervical ganglion, Ashe and Libet recorded a late, slow excitatory postsynaptic potential in response to preganglionic nerve stimulation in the presence of nicotinic and muscarinic antagonists[4]. We have found, in the rat superior cervical ganglion, that a postsynaptic biochemical consequence of preganglionic nerve stimulation, namely the acute activation of tyrosine 3-monooxygenase (tyrosine hydroxylase, TH; EC 1.14.16.2), is mediated in part by acetylcholine and in part by a non-cholinergic neurotransmitter[5]. The regulation of this enzyme activity is of particular interest because it catalyses the rate-limiting step in the biosynthesis of the postganglionic neurotransmitter, noradrenaline. In the present paper, we report that the relative importance of cholinergic and non-cholinergic transmission in the regulation of TH activity varies with the pattern of electrical stimulation of the preganglionic nerve trunk.

Male Sprague Dawley rats (160–200 g) were used in all studies. The rats were killed by cervical dislocation and their superior cervical ganglia rapidly removed, desheathed and maintained *in vitro* at 37 °C as previously described[5]. The preganglionic nerve trunk of one ganglion was stimulated via a suction electrode, and the effectiveness of the stimulation was monitored throughout the stimulation period by recording, via a second suction electrode, the compound action potentials elicited in the postganglionic internal carotid nerve. Except where noted, the current intensity used was twice that required to give a maximum compound action potential. Contralateral control ganglia from the same animals were maintained in similar conditions but were not stimulated. To initiate the measurement of the rate of tyrosine hydroxylation, brocresine (150 μM), an inhibitor of dopa decarboxylase, was added to the incubation medium 2 min before stimulation was begun. At the end of the stimulation period, stimulated and control ganglia were individually homogenized. The respective incubation media were added to the homogenates, and the combined samples were chilled on ice and then centrifuged for 2 min in a Beckman Microfuge. The supernatants were stored at −20 °C before determination of their dopa content by high performance liquid chromatography with electrochemical detection as described elsewhere[5,8]. We have shown previously (1) that dopa is not detectable in ganglia incubated in the absence of brocresine, (2) that dopa accumulation in the presence of brocresine is blocked by 3-iodo-tyrosine, an inhibitor of TH, and (3) that dopa, once accumulated, is stable under our incubation conditions for at least 30 min. Thus dopa accumulation is a valid measure of tyrosine hydroxylation in this preparation[8].

Preganglionic nerve stimulation at 10 Hz for 30 min resulted in about a 5-fold increase in dopa synthesis (Fig. 1). Addition of the nicotinic antagonist, hexamethonium (3 mM) and the muscarinic antagonist, atropine (6 μM) to the incubation medium inhibited the increase in dopa synthesis by 50% (Fig. 1). The concentration of hexamethonium used completely blocked the compound action potentials normally recorded during preganglionic nerve stimulation (data not shown), and the concentration of atropine used has been shown by others to block the muscarinic postsynaptic electrophysiological responses elicited by such stimulation[9,10]. However, in the presence of both of these antagonists, nerve stimulation still produced a significant (approximately 3-fold) increase in dopa synthesis. When the preganglionic nerve was stimulated with 10 Hz bursts (10 Hz for 1 out of every 6 s) for 30 min, dopa

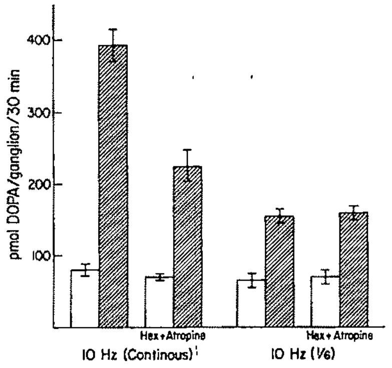

Fig. 1 Effect of cholinergic antagonists on the increase in dopa synthesis produced by preganglionic nerve stimulation. Ganglia were stimulated for 30 min either at 10 Hz continuously or at 10 Hz for 1 out of every 6 s. Hexamethonium (Hex, 3 mM) and atropine (6 μM) were added to certain preparations 10 min prior to the beginning of stimulation. The data represent the mean ±s.e.m. of 4–6 ganglia. Control ganglia, open bars; stimulated ganglia, hatched bars.

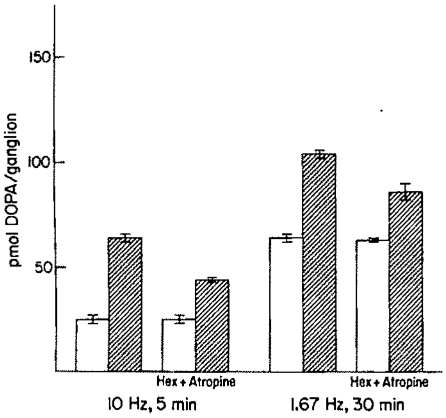

Fig. 2 Evidence for cholinergic and non-cholinergic regulation of tyrosine hydroxylase activity during continuous preganglionic nerve stimulation. Ganglia were stimulated at 10 Hz for 5 min or at 1.67 Hz for 30 min. Hexamethonium (Hex, 3 mM) and atropine (6 μM) were added to certain preparations 10 min before stimulation. The data represent the means ±s.e.m. of 4–5 ganglia. Control ganglia, open bars; stimulated ganglia, hatched bars.

synthesis was elevated by 2.4-fold (Fig. 1). Under these conditions, the increase in dopa production was not lessened at all by the addition of hexamethonium and atropine (Fig. 1). On the other hand, the compound action potentials were blocked by these antagonists under both stimulation conditions (data not shown).

The pharmacology of the acute transsynaptic regulation of TH differs under these two stimulation conditions. These results indicate that the increase in TH activity following continuous stimulation at 10 Hz is partially mediated by acetylcholine and partially by a non-cholinergic transmitter, as we have previously reported[5]. However, the increase in TH activity produced by stimulation with 10 Hz bursts is mediated entirely by a non-cholinergic mechanism. The two patterns of nerve stimulation examined differ in two respects; that is, in the total number of pulses delivered (which is six times greater in the continuous pattern) and in the temporal distribution of the pulses. The effects of two other stimulation conditions were examined to determine if one of these factors is particularly important in determining whether or not a cholinergically mediated stimulation of dopa synthesis occurs. Under each of these conditions, the same number of pulses was delivered as in the 10 Hz burst pattern. Preganglionic nerve stimulation at 10 Hz for 5 min increased dopa synthesis by 2.5-fold (Fig. 2). This effect of nerve stimulation was decreased by 43% by adding hexamethonium and atropine (Fig. 2). Continuous stimulation at 1.67 Hz for 30 min led to a smaller (62%) increase in dopa synthesis, which was reduced by 42% by the addition of the cholinergic antagonists (Fig. 2).

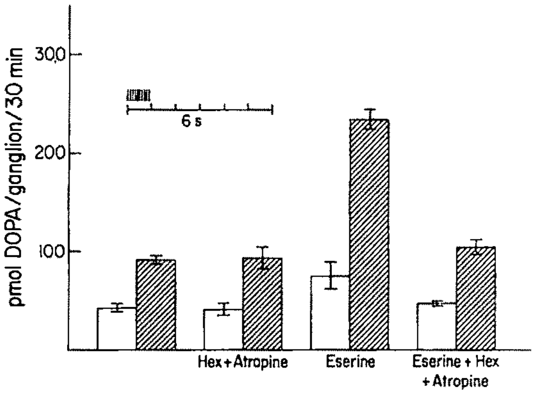

Fig. 3 Effects of physostigmine (eserine) and cholinergic antagonists on the increase in dopa production following "discontinuous" stimulation. Ganglia were stimulated at 10 Hz for 1 out of every 6 s for 30 min. Eserine (20 μM) and/or hexamethonium (Hex, 3 mM) and atropine (6 μM) were added to certain preparations 10 min before stimulation was begun. The current intensity used was that required to give a maximum compound action potential. In this experiment, the incubation medium used was Earle's balanced salt solution. In all other experiments reported in this paper, Kreb's bicarbonate buffer was used. The data represent the mean ±s.e.m. of 3–5 ganglia. Control ganglia, open bars; stimulated ganglia, hatched bars. The stimulation pattern is shown diagrammatically at the top of the figure.

These data suggest that the temporal distribution, rather than the number, of impulses is the important factor in determining the occurrence of a cholinergically mediated increase in TH activity. Perhaps preganglionic nerve stimulation for brief periods (for example 1 s) followed by prolonged periods of inactivity (for example 5 s) does not provide a sustained enough cholinergic stimulation of the postganglionic neurones to elevate TH activity. Acetylcholine is rapidly cleared from the synaptic region following a nerve impulse[3,11], due to activity of the enzyme acetylcholinesterase and to diffusion away from the synaptic cleft. Such a rapid removal of acetylcholine may be essential for its role in transmitting electrophysiological information as the continuous presence of a cholinergic agonist can lead to desensitization of the action potential triggering mechanism in sympathetic ganglia, as it does at the neuromuscular junction[12]. However, a brief exposure to an agonist, although suitable for triggering action potentials, may not be suitable for a sustained activation of an enzyme like TH. To investigate whether the degradation of acetylcholine prevents the expression of a cholinergic component in the regulation of TH during discontinuous nerve stimulation, ganglia were stimulated with 10 Hz bursts in the presence or absence of the acetylcholinesterase inhibitor, physostigmine. In agreement with the data reported in Fig. 1, stimulation with this discontinuous pattern produced about a 2-fold increase in dopa synthesis, which was completely resistant to cholinergic antagonists (Fig. 3). Addition of physostigmine (20 μM) to the incubation medium significantly elevated the rate of dopa synthesis in both control and stimulated ganglia (Fig. 3). These effects of physostigmine were completely blocked by hexamethonium and atropine (Fig. 3). Physostigmine thus causes the expression of a cholinergic component of TH regulation during discontinuous nerve stimulation, either by increasing the amount of acetylcholine in the synaptic cleft, or by prolonging the duration of cholinergic stimulation or by both.

We do not know yet which transmitter is responsible for the non-cholinergic elevation of TH activity. So far, after screening a large number of peptides and other transmitter candidates, we have found that secretin, vasoactive intestinal peptide (VIP) and PHI (which refers to a 27-amino acid peptide that has a histidine at the N-terminal and an isoleucine amide at the

C-terminal) can mimic this non-cholinergic effect of nerve stimulation[13,14]. Many other peptides tested, including glucagon, substance P, methionine-enkephalin, luteinizing hormone releasing hormone, and angiotensin had no effect on TH activity. The idea that certain neuropeptides may function as neurotransmitters in specific autonomic ganglia is now widely accepted[15]. Although we have not yet established that the non-cholinergic elevation of TH activity produced by preganglionic nerve stimulation is mediated by a neuropeptide, it is interesting to note that one characteristic of the electrophysiological effects of peptides, which has been commonly observed, is their long duration (for example, changes in resting potential lasting for a minute or longer, see refs 7, 16 for examples). Such a time course is compatible with our finding that the non-cholinergic (but not the cholinergic) regulation of dopa synthesis is present during a bursting pattern of nerve stimulation. Thus the postsynaptic consequences of a neuropeptide, unlike that of acetylcholine, might be sustained throughout the interburst interval. The magnitude of peptidergic postsynaptic effects may also be affected by the pattern of nerve stimulation. Thus, in certain peptidergic neurones, such as the VIP-containing parasympathetic neurones innervating the cat submandibular gland and the vasopressin- and oxytocin-containing neurones of the hypothalamo-hypophyseal system, the release of peptides is greater when impulses are delivered in high frequency bursts, rather than continuously at the same average frequency[17,18]. Perhaps a similar mechanism accounts for the fact that while the non-cholinergic component of TH regulation is present during continuous stimulation at a low frequency (1.67 Hz), its magnitude appears to be enhanced by delivering the same number of impulses intermittently in bursts at a higher frequency (10 Hz for 1 out of every 6 s) (Figs 1 and 2). Significantly, studies on the physiological discharge pattern in sympathetic neurones have demonstrated that the electrical activity *in vivo* often occurs in brief bursts separated by periods of inactivity[3,19]. Perhaps, in certain conditions (for example certain types of stress) a more continuous pattern of preganglionic nerve activity occurs, thus activating a second (cholinergic) mechanism for elevating noradrenaline synthesis.

Recent studies on the colon demonstrate that the nature of the tissue response to nerve stimulation (that is, whether vasodilation or contraction of the colon occurs) is dramatically altered by changing the pattern of stimulation[20]. These responses may well be mediated by different neurotransmitters. In the present study, we have found that the pattern of stimulation determines the relative importance of different transmitters in regulating a single postsynaptic response, namely the stimulation of catecholamine biosynthesis.

Giant synaptosomes

J. A. Umbach, C. B. Gundersen* & P. F. Baker†

Department of Physiology, King's College London, Strand,
London WC2R 2LS, UK

* Department of Biophysics, University College London, Gower Street,
London WC1E 6BT, UK

Investigations using synaptosomes, pinched-off nerve ending particles from brain[1,2], have greatly improved our knowledge of presynaptic function. However, these structures, like most nerve endings, are too small to be penetrated with microelectrodes. We have treated synaptosomal preparations from rat brain with a neutral protease and obtained fused structures large enough to be recorded from directly with microelectrodes; we report here that these particles (30–250 μM in diameter) contain mitochondria and structures resembling synaptic vesicles, morphological features characteristic of synaptosomes. These 'giant synaptosomes' have resting membrane potentials in the range −45 to −76 mV, are depolarized by increasing concentrations of K^+, show responses to a variety of neuroactive substances and exhibit active membrane responses to depolarizing current pulses. These results suggest that this preparation will be of value in further studies of nerve terminal function.

Synaptosomal fractions were prepared from the brains of Wistar rats (25–100 g) using differential and sucrose gradient centrifugation as described[1], except that the initial homogenization step was performed by hand. The synaptosomal pellet from one brain was dispersed in approximately 0.5 ml of sucrose (0.32 M); neutral protease (dispase, Boehringer-Mannheim) was then added to a concentration of 0.1–0.2 mg ml^{-1}. The mixture was incubated for 30–40 min at 20–23 °C and samples were examined for fused synaptosomes using a light microscope. The number of giant particles formed (Fig. 1*a*) was in the range of 0–4 per preparation of synaptosomes. Giant particles failed to form in about half of the preparations.

Electron microscope investigation of these particles is difficult, mainly because of the low success rate of their formation. Nevertheless, the interior of the particles is nearly devoid of electron-dense material (Fig. 1*b*, *c*). Clustered along the limiting membrane there are mitochondria and occasional vesicles or clusters of vesicles of 40–60 nm diameter. Of the 10 particles examined in this way, none has contained ribosomes, rough endoplasmic reticulum or nuclei, which suggests that cell bodies do not participate in the genesis of these structures. The 40–60 nm vesicles could be synaptic vesicles, which along with mitochondria, are features typical of synaptosomes[1]. Also consistent with the interpretation that these giant particles derive from synaptosomes is the fact that similar structures have not been obtained either using the P_2 (crude mitochondrial fraction of Gray and Whittaker[1]) or the myelin or mitochondrial fractions from the sucrose gradients used to isolate the synaptosomes. Provisionally, we will call the fused structures giant synaptosomes.

For electrophysiological investigation, the giant synaptosomes were first incubated in a solution of 190 mM potassium phosphate (*p*H 7.2), 10 mM NaCl, 2 mM $MgCl_2 \cdot 7H_2O$ and 10 mM glucose. After 10 min, the particles were transferred to physiological saline [135 mM NaCl, 5 mM KCl, 2 mM $CaCl_2$, 1 mM $MgCl_2$, 0.5 mM Na_2HPO_4, 1 mg ml^{-1} glucose and 20 mM HEPES (*p*H 7.2 with NaOH] and impaled with conventional microelectrodes (20–40 MΩ filled with 3M KCl). On electrode insertion, resting potentials in the range −45 to −76 mV (mean −55 mV; $n = 26$) were obtained (Fig. 2*a*). Giant synaptosomes were usually depolarized in a nernstian fashion by increasing concentrations of KCl (Fig. 2*a*, *b*). However, synaptosomes with a resting potential smaller than −50 mV often showed less than

Along the limiting membrane are structures which may represent small mitochondria and dense-cored vesicles. Note the lack of electron-dense organelles towards the interior of the particle. *c*, *d*, Examples of mitochondria found along the limiting membrane of giant synaptosomes. *e*, Cluster of vesicles, which may include synaptic vesicles, found near the surface membrane of a giant synaptosome. Scale bar corresponds to: 50 μm (*a*), 500 nm (*b*, *c*); 200 nm (*d*); 150 nm (*e*). **Methods:** Samples were processed for electron microscopy as follows. At 4 °C: 1-h wash in physiological saline, 4–6 h of fixation in 6% glutaraldehyde in 0.1 M cacodylate buffer (*p*H always at 7.4). At 20 °C: four 1-h washes with 0.2 M cacodylate buffer, 4–8 h postfixation in 2% osmium tetroxide in 0.1 M cacodylate buffer, two 1-h washes with 0.2 M cacodylate buffer, dehydration in a graded ethanol series followed by four 1-h rinses in 100% ethanol. Samples were transferred first to propylene oxide (two 15-min exposures), then to 1 : 1 propylene oxide/epon (12 h) followed by evaporation of the propylene oxide and finally to epon (three 30-min changes, followed by incubation overnight at 60 °C). Throughout this procedure (except when in epon) samples were rotated slowly. Sections were cut and stained with uranyl acetate and alkaline lead citrate for viewing in a JEOL electron microscope.

nernstian responses to changes of external K^+ concentration. Equimolar replacement of either extracellular Cl^- by isethionate or Na^+ by choline had little effect on the resting membrane potential. These data suggest that K^+ permeability is the major determinant of the resting membrane potential in these structures.

Insertion of a second electrode into the giant synaptosome revealed that the interior was isopotential. When passing current through one electrode, a voltage response was recorded by the second electrode (Fig. 3). In many of the giant synaptosomes, depolarizing current pulses elicited a regenerative, transient spike which was graded with the stimulus intensity. This regenerative response was affected by changes in either external Ca^{2+} or Na^+ (Fig. 3*a*, *b*). The spike could be partially blocked by either Co^{2+} or tetrodotoxin (TTX) (Fig. 3*c*, *d*) and completely eliminated in the presence of both of these substances (Fig. 3*e*). Application of veratrine (100 μg ml^{-1}) depolarized the giant synaptosomes ($n = 3$) by 25–30 mV. Recovery of the membrane potential after veratrine required long wash-out periods (> 10 min). These data suggest that voltage-gated channels for Na^+ and Ca^{2+} are present in the plasma membrane of the fused synaptosomes. A pronounced hyperpolarization was usually

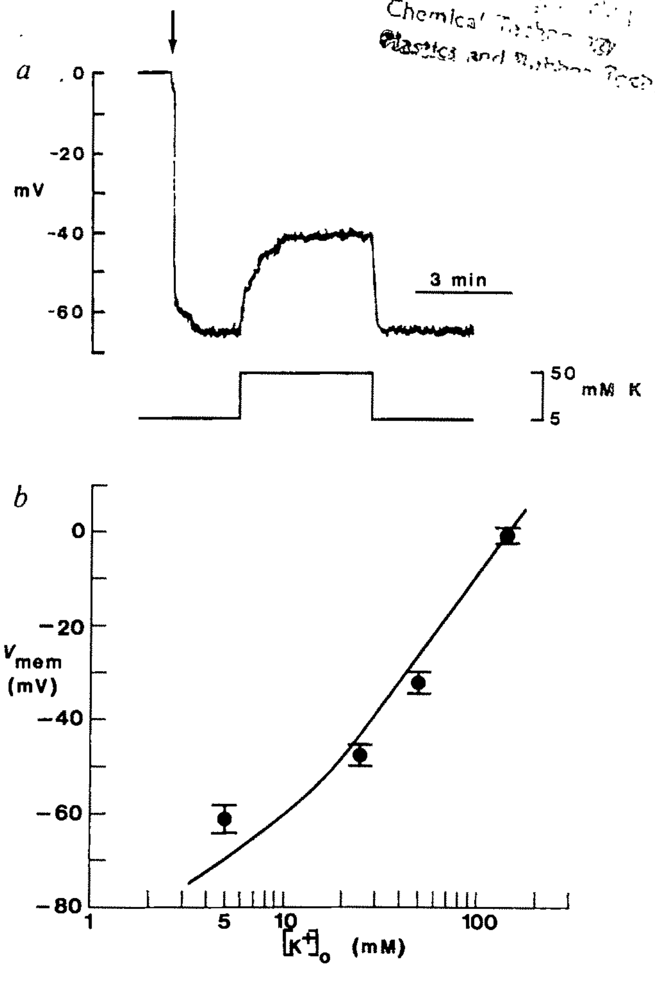

Fig. 2 *a*, Membrane potential records from a giant synaptosome. A giant particle was impaled (arrow) while in physiological saline ($K^+ = 5$ mM). Subsequently, the K^+ concentration of the medium was increased to 50 mM (by isotonic substitution for NaCl). The membrane potential was fully recovered on removal of high K^+. Temperature, 22 °C. *b*, Plot of membrane potential (V_{mem}) against extracellular K^+ concentration. Results are the mean±s.e.m. of nine experiments. The curve was calculated using the equation: $V_{mem} = 2.3\,(RT/F)\log([K]_o + \alpha[Na]_o) + B$, for $B = 48$ mV and $\alpha = 0.025$ (see ref. 8). B is equivalent to $-2.3(RT/F)\log([K]_i + [Na]_i)$, and is treated as a constant by assuming that the internal cation concentration does not change; α is equivalent to (P_{Na}/P_K), the permeability ratio between Na and K ions.

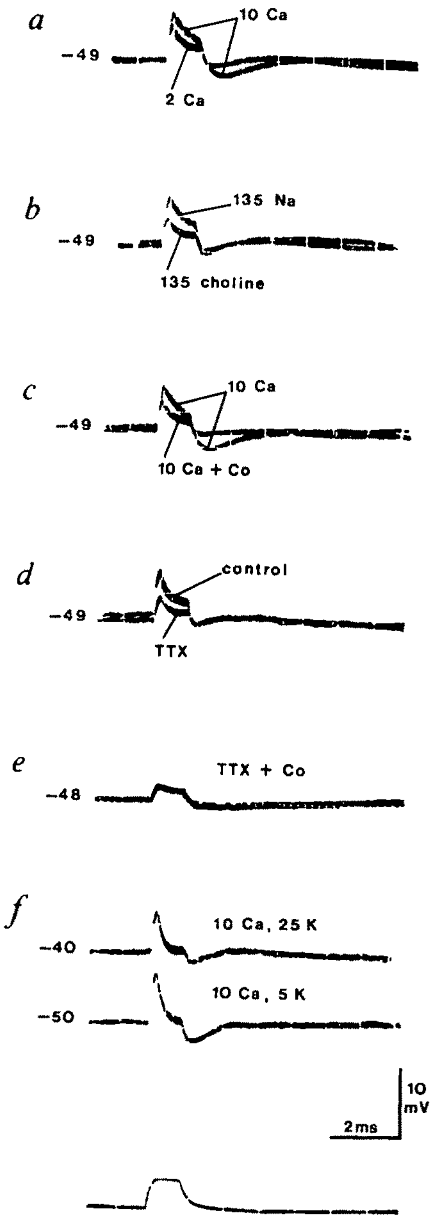

Fig. 3 Voltage records obtained during depolarizing current pulses. A single giant synaptosome was exposed to solutions of different composition as indicated: *a*, Physiological Ringer's with normal (2 mM) or high (10 mM) $CaCl_2$ (NaCl reduced to maintain tonicity). *b*, Physiological Ringer's with normal (135 mM)NaCl or replacement of NaCl by choline chloride. *c*, High calcium Ringer's (see *a*) or high calcium Ringer's plus 10 mM $CoCl_2$ (NaCl reduced to maintain tonicity). *d*, Normal Ringer's or normal Ringer's plus 1 μg ml^{-1} tetrotoxin (TTX). *e*, Normal Ringer's plus 1 μg ml^{-1} TTX and 10 mM $CoCl_2$. *f*, High calcium Ringer's containing normal (5 mM) or raised (25 mM) KCl (NaCl was altered to maintain tonicity). Resting potential is indicated to the left of each trace. An example of the 100 nA current pulse used to elicit these responses is shown at the bottom of the figure. Temperature, 20 °C.

observed at the offset of the stimulus (Fig. 3). This afterhyperpolarization was dependent on the concentration of extracellular calcium (Fig. 3*a*), attenuated in high K^+ solutions (Fig. 3*f*) and could be blocked by extracellular Co^{2+} (Fig. 3*c*). TTX minimally affected this hyperpolarization (Fig. 3*d*). These results are consistent with the presence of a calcium-activated K^+ conductance in these structures.

In many experiments the giant synaptosomes were sensitive to several neuroactive substances. Individually, glutamate, acetylcholine (ACh), serotonin and noradrenaline elicited depolarizing responses (Fig. 4). However, with some synaptosomes ACh induced a hyperpolarization (Fig. 4*e*). Both of these ACh responses were reversibly blocked by equimolar atropine (data not shown). Note that the concentrations of the substances used in Fig. 4 are 10^{-4}–10^{-2} M. However, the threshold concentration for eliciting these effects was usually 10^{-5}–10^{-4} M.

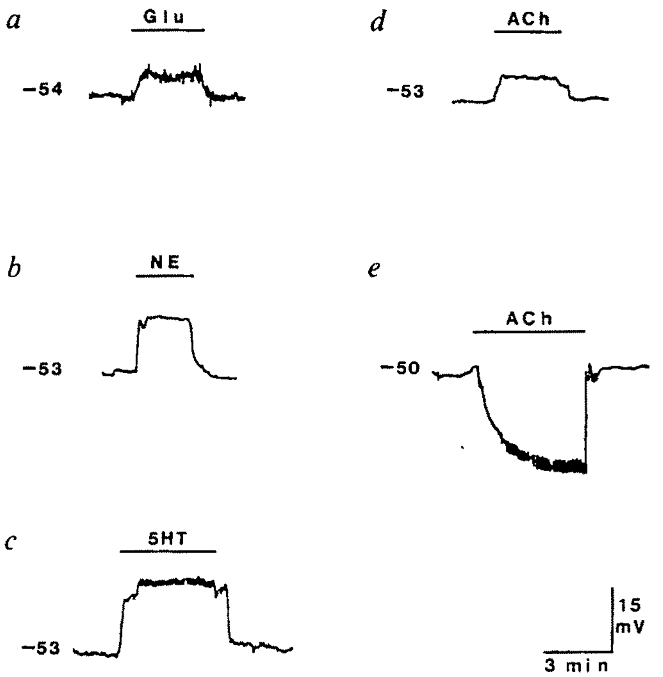

Fig. 4 Membrane response of giant synaptosomes on addition of putative neurotransmitters to the bathing medium. *a*, Glutamate 10^{-4} M); *b*, noradrenaline (10^{-3} M); *c*, serotonin (10^{-2} M); *d*, acetylcholine (10^{-2} M); and *e*, acetylcholine (10^{-2} M). Records *a* and *d* from separate giant synaptosomes; *b*, *c* and *e* from the same giant synaptosome. Resting potentials are given to the left of each trace. Temperature, 22 °C.

The above results are consistent with the suggestion that the giant particles derive from the fusion of a large number of synaptosomes. These particles retain (1) mitochondria and structures resembling synaptic vesicles, (2) a stable resting potential, (3) voltage-activated Na^+ and Ca^{2+} channels and Ca^{2+}-activated K^+ channels and(4) electrical responses to putative neurotransmitter agents. These are all properties expected of presynaptic nerve terminals[1–5]. Moreover, we failed to obtain similar structures either from crude synaptosome fractions or the other fractions from the sucrose gradient. However, we cannot exclude the possibility that both postsynaptic and non-synaptosomal elements may be involved in the formation of the particles that we obtained. Future use of antibodies that specifically recognize nerve terminals (see ref. 4) will be of value in clarifying this point.

Preparations of mammalian brain synaptosomes are heterogeneous with respect to the neurotransmitter and transmitter receptors carried by individual synaptosomes[5]. Thus, it is likely that the giant synaptosomes are obtained by the fusion of a similarly mixed population of particles. This line of reasoning suggests that studies of these particles might best be performed using populations of synaptosomes that are enriched in a particular class of nerve ending (for example, cholinergic, adrenergic). Extending this to the present data, we suggest that the high concentration of the putative neurotransmitters required to evoke the responses recorded in Fig. 4 may derive from the relative paucity of appropriate receptors on these hybrid particles. Alternatively, it may be that such presynaptic receptors do not become operational until a high concentration of the appropriate substance is present. This preparation should allow one to distinguish between these two explanations.

The preparation of these giant particles entailed the exposure of synaptosome preparations to dispase. Protease treatments have occasionally been found to encourage the fusion of other types of structures[6]. While we cannot exclude the possibility that dispase modified some of the membrane properties associated with the giant particles, we note that proteases are often used without detriment to prepare membranes for single-channel recording (see ref. 7). As such, this preparation may be used advantageously to study the characteristics of single channels and receptors in the nerve terminal membrane.

Assuming that these structures represent the fusion of large numbers of synaptosomes, one would expect a large dilution (on the basis of surface area/volume considerations) of the particle's cytoplasmic constituents by the sucrose medium in which fusion took place; this notion is consistent with the meagre amount of electron-dense material observed within these particles. However, the attendant dilution of the internal ionic milieu raises the question of how the resting potential of these particles is established. The data of Fig. 2 indicate that K^+ is the principal contributor to the resting membrane potential. Further studies should elucidate how this ion gradient is generated and maintained.

We thank Professor R. Miledi for encouragement, support and laboratory facilities, Mrs Carol Limbrick for electron microscope examination of specimens and Dr D. Knight for helpful discussions. This research was carried out during the tenure of a Muscular Dystrophy Association postdoctoral fellowship to J.A.U. We thank the MRC for support.

42,000-molecular weight EGF receptor has protein kinase activity

Mitali Basu, Rupamanjari Biswas & Manjusri Das

Department of Biochemistry and Biophysics, University of Pennsylvania, Philadelphia, Pennsylvania 19104, USA

The epidermal growth factor (EGF) receptor and other growth factor receptors have been shown to possess tyrosine-specific protein kinase activity[1–5]. Before the demonstration of kinase activity in growth factor receptors, tyrosine kinases of molecular weight (MW) 60,000 (60K) were found to be encoded by the *src* oncogene and other oncogenes related to *src*[6–8]. Our earlier work on intracellular processing of the EGF receptor[9], a 170,000-MW polypeptide, provided evidence for proteolytic separation of well defined structural domains, and suggested to us the possibility of separating functional domains by limited proteolysis. The isolation of such kinase domains should facilitate comparison of the receptor/kinase with other well characterized kinases including those of oncogene origin. We report here the identification of a catalytically functional 42K kinase derived proteolytically from the isolated human EGF receptor. This fragment, comparable in size to pp60^{src}, carries the kinase ATP-binding site, and functions catalytically even after detachment from the EGF-binding site and the major autophosphorylation region.

We used 5′-fluorosulphonylbenzoyl[^{14}C]adenosine(5′-*p*-FSO$_2$bz[^{14}C]A) to screen for kinase site-containing fragments in tryptic digests of the solubilized purified receptor[10,11]. This ATP analogue irreversibly modifies ATP-binding sites[12–14], and inhibits phosphorylation of both the solubilized purified receptor and a receptor-derived peptide fragment (see below).

Treatment of the freshly purified EGF receptor preparation with 50 μM 5′-*p*-FSO$_2$bz[^{14}C]A at 20 °C for 30 min resulted in radiolabelling of two bands of 170K and 150K (Fig. 1*a*, lane *a*). Measurement of radioactivity in the 170K and 150K bands revealed incorporation of 0.5–0.7 mol of 5′-*p*-SO$_2$bz[^{14}C]A per mol, indicating ~1 ATP-binding site per mol of receptor molecule (measured in terms of EGF-binding sites).

Pretreatment of the receptor with 2 μg ml^{-1} trypsin at 20 °C for 30 min, followed by incubation with 5′-*p*-FSO$_2$bz[^{14}C]A, resulted in the appearance of radiolabel in two bands of 150K and 42K (Fig. 1*A*, lane *b*). Pretreatment with higher concentrations of trypsin (5 μg ml^{-1} and 9 μg ml^{-1}) resulted in covalent radiolabelling of only a single sharp band of 42K (Fig. 1*A*, lanes *c*, *d*). Only the 42K peptide and no other peptide smaller than 150K carried the affinity label.

The total amount of ^{14}C-label incorporated into the three bands (170K, 150K and 42K) was the same for trypsin-treated and untreated receptor preparations. Thus, the single kinase site of the receptor polypeptide is quantitatively recovered in the 42K fragment.

Experiments were done to determine whether the pre-labelled intact receptor would generate, on trypsin treatment, a ^{14}C-labelled 42K peptide (Fig. 1*B*). After labelling of the intact receptor with 5′-*p*-FSO$_2$*bz*[^{14}C]A, the unreacted reagent was removed and the preparation treated with 5 μg ml^{-1} trypsin. Amost all the radiolabel originally present in the intact receptor band appeared in the 42K band (Fig. 1*B*). Thus, the receptor is the precursor of the 42K peptide, and this peptide retains the full kinase ATP-binding activity of the receptor.

The ATP analogues, AMP-PNP and 5′-*p*-FSO$_2$bzA, at a concentration of 1 mM, abolished labelling with 50 μM 5′-*p*-FSO$_2$bz[^{14}C]A by more than 90% (Fig. 1*C*). Labelling was also abolished by pretreatment with *N*-ethylmaleimide or heat (Fig. 1*C*).

It would be interesting to know whether the 42K fragment, like other protein kinases, is capable of autophosphorylation. Phosphorylation of the purified receptor with [γ-^{32}P]ATP gave a major band of labelling at 170K and a minor band at 150K (Fig. 2*A*, lane *a*). When phosphorylation was preceded by a 30 min exposure of the receptor to 2 μg ml^{-1} trypsin, the 170K band largely disappeared (Fig. 2*A*, lane *b*). Trypsin-induced conversion of the 170K form to the 150K form was associated with a large loss (>90%) of autophosphorylation sites (although, as indicated above, there was no loss of ATP-binding sites). Pretreatment of the receptor with higher concentrations of trypsin (5 and 9 μg ml^{-1}), followed by incubation with [γ-^{32}P]ATP, resulted in the labelling of a single sharp band of 42K (Fig. 2*A*, lanes *c*, *d*). Only the 42K peptide, and no other peptide smaller than 150K carried the ^{32}P label.

The phosphorylation that occurs on the 42K fragment as well as on the 170K/150K receptor involves tyrosine residues only (studied by standard phosphoamino acid analysis). Also, a tyrosine kinase-specific substrate, Arg-Arg-Leu-Ile-Glu-Asp-Ala-Glu-Tyr-Ala-Ala-Arg-Gly[15], was phosphorylated by the 42K peptide at a rate of 0.7 mol peptide phosphorylated mol^{-1} min^{-1} (not shown). (The rate for the intact 170K receptor was 2.5 mol peptide phosphorylated mol^{-1} min^{-1}. These results support the conclusion that the 42K peptide is an active tyrosine kinase. Several ATP analogues or pretreatment with *N*-ethylmaleimide or heat completely abolished the autophosphorylation of the 42K peptide (Fig. 2*B*). It is significant that the active sites in both the intact receptor protein and the 42K tryptic fragment exhibit similar reactivity with the reagents. The inhibitory effects of the ATP analogues could be abolished with excess [γ-^{32}P]ATP. The results described above indicate that the 42K fragment carries the kinase ATP-binding site and that it can be phosphorylated in the unfractionated tryptic digest.

Is the fragment a self-sufficient catalytic entity? We investigated the activity of the 42K fragment after electrophoretic fractionation of the trypsin digest on non-denaturing (SDS-free) gels (Fig. 2*C*). The unproteolysed receptor (170K/150K, form) was recovered largely in gel slice 2 and the 42K fragment in slice 6; these, together with the other slices, were incubated with [γ-^{32}P]ATP and the phosphorylated species were subsequently visualized by SDS-gel electrophoresis and autoradiography (Fig.

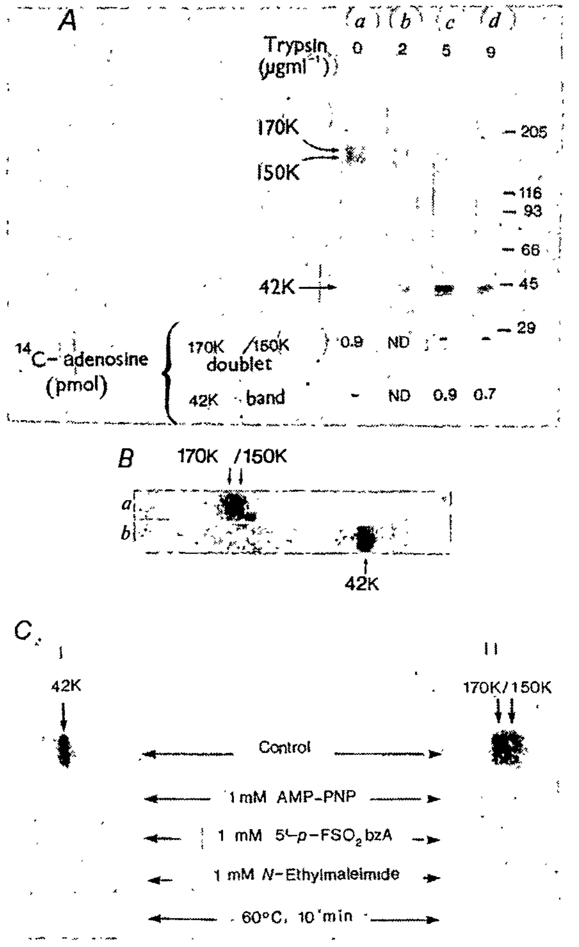

Fig. 1 Affinity labelling of EGF receptor fragments with a ^{14}C-ATP analogue monitored by SDS-polyacrylamide gradient gel electrophoresis. *A*, Trypsinization of the receptor, followed by incubation with 5'-p-FSO$_2$bz[^{14}C]A. *B*, Trypsin fragment of the pre-labelled receptor. *C*, Effect of inhibitors of EGF receptor kinase on ^{14}C affinity labelling of the 42K peptide.

Methods: *A*, Receptor (1.5 pmol, see below) was incubated at 20 °C for 30 min with the indicated amounts of trypsin (crystalline, tosylphenylethylchloromethylketone-treated; Sigma) in 20 μl of 20 mM HEPES *p*H 7.4, 10% glycerol, 0.2% Triton X-100. Trypsin action was stopped by adding 1 μl soybean trypsin inhibitor solution (10 mg ml^{-1}) to all tubes, followed by the addition of 5 μl of solution containing 20 mM HEPES *p*H 7.4, 5 mM MnCl$_2$. Labelling was initiated by adding 1 μl of a 1.25 mM solution of 5'-*p*-FSO$_2$bz[^{14}C]A (50 Ci mol^{-1}; NEN) in dimethylformamide. After incubation at 20 °C for 30 min, the reaction was stopped by adding rapidly in succession 2 μl of 10 mg ml^{-1} bovine serum albumin (BSA) and 1 ml of ice-cold 10% trichloroacetic acid (TCA). The precipitate was dissolved in SDS sample buffer and subjected to 5–20% polyacrylamide gradient SDS-gel electrophoresis. After staining and destaining, the gels were prepared for fluorography by immersion in dimethyl sulphoxide (DMSO) containing 2,3'-diphenyloxazole. The gels were then autoradiographed for 40 days using Kodak X-Omat AR films and Dupont Cronex Lightening Plus intensifying screens. After autoradiography, the regions of the dried gel containing the 170K/150K doublet or the 42K band were cut out and counted using toluene-based scintillation fluid. Adjacent regions of the dried gel were similarly counted to determine background radioactivity. In these counting conditions the specific radioactivity of 5'-*p*-FSO$_2$bz[^{14}C]A was ~100 c.p.m. pmol^{-1}. *B*, Intact receptor (4 pmol) was labelled with 50 μM 5'-*p*-FSO$_2$bz[^{14}C]A as described above, then the mixture (100 μl) was diluted with 10 ml of 20 mM HEPES *p*H 7.4, 10% glycerol, 0.2% Triton X-100, and concentrated by Amicon ultrafiltration (using PM-30 filters) to 0.2 ml. The dilution and filtration–concentration steps were repeated three times. The ^{14}C-labelled receptor, free of excess reagent, was incubated without (*a*) or with (*b*) or 5 μg ml^{-1} trypsin at 20 °C for 30 min. TCA-precipitable proteins were subjected to electrophoresis and autoradiography. *C*, Receptor (1.4 pmol) was either treated with 5 μg ml^{-1} trypsin (I) or untreated (II), then incubated in the conditions indicated, followed by incubation with 50 μm 5-*p*-FSO$_2$bz[^{14}C]A as described for *A*. Labelled proteins were isolated by acid precipitation and visualized by electrophoresis and autoradiography. Receptor isolation method: Plasma membranes were isolated from 2×10^8 human A431 epidermoid carcinoma cells as described[10,11] using Ca^{2+} and Mg^{2+}-free solutions. The membranes (2 mg protein) were stirred at 20 °C for 30 min with 1 ml of a solution containing 20 mM HEPES *p*H 7.4, 10% glycerol, 1% Triton X-100, and 10 μg ml^{-1} leupeptin. After centrifugation at 100,000*g* for 70 min, the supernatant was added to 0.5 ml of packed EGF–agarose containing 0.4 mg of covalently bound EGF[10,11]. After stirring at 20 °C for 30 min, the gel pellet was washed four times at 4 °C with 2 ml of a solution containing 10% glycerol and 0.2% Triton X-100, and the receptor eluted by stirring the washed gel three times (10 min at 4 °C each time) with 1 ml of 5 mM ethanolamine solution *p*H 10, containing 10% glycerol and 0.2% Triton X-100, and immediately brought to *p*H 7.0 with 0.05 M HCl[10]. The amount of receptor present was estimated by Scatchard analysis of ^{125}I-labelled EGF binding data, assuming a 1 : 1 complex of EGF and receptor. Recoveries varied from 40 to 60% of the input solubilized activity. The K_d binding to ^{125}I-labelled EGF was ~25 nM.

2*B*). The 42K fragment, separated in this way from the uncleaved receptor and from other receptor fragments, displayed kinase and autophosphorylating activity. These results confirm that the 42K peptide carries the entire self-sufficient kinase active site.

We investigated the relationship of the 42K fragment and the major autophosphorylation locus. Over 90% of the kinase activity sites (measured by labelling with the ^{14}C-labelled ATP analogue) in the intact receptor are recovered in the 42K peptide (Fig. 1). In contrast, only 5% of the autophosphorylation sites (measured by [γ-^{32}P]ATP labelling) are retained in the 42K peptide (Fig. 2*A*). The major autophosphorylation locus seems to lie in a 15K fragment that is cleaved off during the conversion of the 170K receptor to the 150K form (Fig. 2*D*). We know that the purified intact 170K receptor can maximally incorporate 6 mol of phosphate per mol of receptor. The phosphate-accepting tyrosine residue retained in the 42K peptide appears to be a minor site whose probability of phosphorylation is low, that is, the ^{32}P-phosphate incorporation is less than would be expected, given the presence in the peptide of one site which can be labelled. The observed low ^{32}P-phosphate incorporation could be due to previous occupancy of the tyrosine site with phosphate.

We next investigated the relationship of the 42K peptide to the EGF-binding site. Autophosphorylation of the 42K peptide was not stimulated by EGF (Fig. 3), and the peptide did not bind EGF, seen by the following assays: (1) covalent attachment of ^{125}I-EGF[16–18]; (2) polyethylene glycol assay[1]; (3) competitive inhibition of receptor binding to EGF–agarose.

We examined whether the 42K peptide represents an adventitious protein in the receptor preparation, or pre-exists as a separable subunit of the receptor. Analysis of the receptor by sucrose density gradient centrifugation revealed the presence of only a 7.7S kinase activity peak that on labelling with [γ-^{32}P]ATP, showed only a 170K major/150K minor doublet band. Thus, the 42K kinase is not present in unproteolysed receptor preparations as a separate or bound (active) entity.

Can the 42K protein pre-exist, either separately or bound to the receptor, in a catalytically inactive form that becomes active on trypsinization? This possibility is excluded by the precursor–product relationship shown in Fig. 1*B*. In these experiments, the ATP-binding site in the 170K receptor, covalently labelled with a ^{14}C-ATP analogue, appeared quantitatively in the 42K peptide.

These results suggest that the EGF receptor has three kinds of functional sites—the EGF-binding site, the protein kinase catalytic site and the major autophosphorylation site(s), located on separate domains. Tryptic processing of the EGF receptor results initially in the generation of an EGF-binding peptide of 150K which retains the kinase/ATP-binding site and a minor autophosphorylation site, but which has lost the major tyrosine-

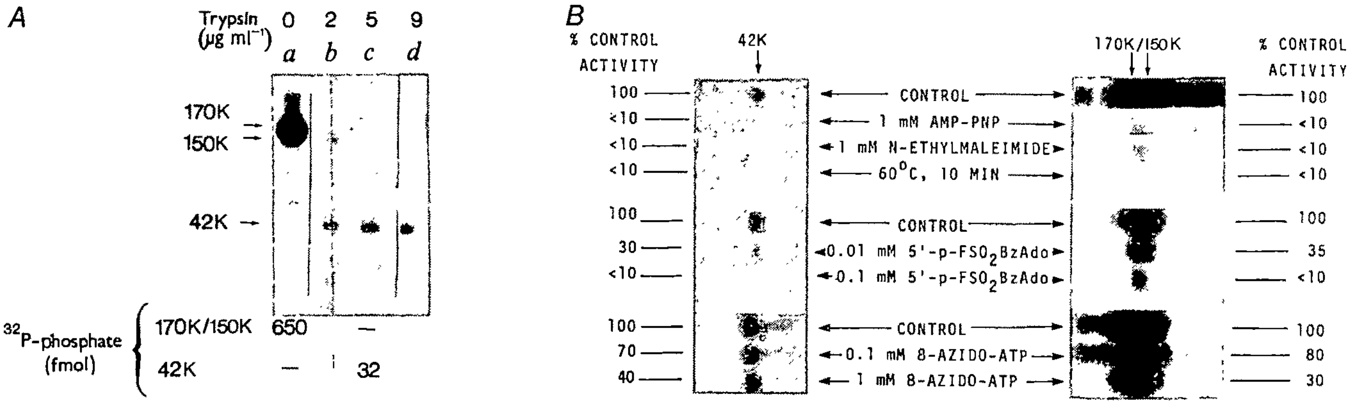

Fig. 2 Phosphorylation of the 42K fragment. *A*, Trypsinization of the receptor followed by incubation of fragments with [γ-^{32}P]ATP. *B*, Effect of inhibitors of EGF-receptor kinase on autophosphorylation of the 42K peptide. *C*, Autophosphorylating activity in gel slices after non-denaturing electrophoresis. *D*, Action of trypsin on the ^{32}P-phosphorylated receptor.

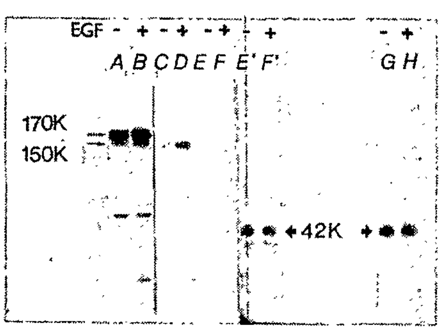
Methods: *A*, Receptor (0.2 pmol) was incubated at 20 °C for 30 min with 10 μl of 20 mM HEPES *p*H 7.4, 10% glycerol, 0.2% Triton X-100 containing the indicated amounts of trypsin; the reaction was stopped by adding 1 μl soybean trypsin inhibitor solution (10 mg ml^{-1}) and 5 μl of a solution containing 80 mM HEPES *p*H 7.4 and 4 mM $MnCl_2$. Phosphorylation was initiated by adding 5 μl of 60 μM [γ-^{32}P]ATP (70 c.p.m. fmol^{-1}). After 30 min at 20 °C, the reaction was stopped by rapid successive additions of 2 μl BSA (10 mg ml^{-1}) and 1 ml ice-cold 10% TCA. The precipitate was subjected to electrophoresis and autoradiography. *B*, Trypsin (5 μg ml^{-1}) digested (I) or undigested (II) receptor (0.1 pmol) was incubated with the indicated reagents at 20 °C for 30 min, or was heated at 60 °C for 10 min. This was followed by a 30 min incubation with 15 μM [γ-^{32}P]ATP. Labelled proteins were isolated by acid precipitation and visualized by electrophoresis and autoradiography. *C*, Receptor (2 pmol) was incubated at 20 °C for 30 min with 80 μl of 20 mM HEPES *p*H 7.4, 10% glycerol, 0.2% Triton X-100 containing trypsin at different concentrations (0, 2, 5 and 9 μg ml^{-1}). After stopping the reaction with 10 μg of soybean trypsin inhibitor, the samples were subjected to non-denaturing 5–20% polyacrylamide gradient gel electrophoresis in the cold (4 °C) at *p*H 8.8 for 9 h (25 mA, 300–400 V). The Triton X-100-containing SDS-free gel and buffer systems used were essentially the same as those of Cohen *et al.*[10]. After the run, each of the four lanes was cut into 11 slices. To each slice was added 0.2 ml of a solution containing 5 μM[γ-^{32}P]ATP, 1 mM $MnCl_2$, 50 mM HEPES *p*H 7.4, and 10 μg of soybean trypsin inhibitor. After incubation at 4 °C for 8 h, then at 37 °C for 30 min in a shaking bath, the liquid was transferred to an Eppendorf tube, together with an additional 0.7 ml of 20 mM HEPES *p*H 7.4, which had been used to rinse the gel slice. Proteins were precipitated by rapid successive additions of 2 μl of 10 mg ml^{-1} BSA and 0.1 ml of 100% TCA. The precipitate was subjected to SDS-gel electrophoresis and autoradiography as described for *A*. The relatively high activity of the 42K band here may be due to its greater stability or elutability compared with the 170K/150K receptor. *D*, Intact receptor (2 pmol) was labelled with 15 μM [γ-^{32}P]ATP at 20 °C for 30 min, as described for *A*. The mixture (100 μl) was then diluted 200-fold with ice-cold 20 mM HEPES *p*H 7.4, 10% glycerol, 0.2% Triton X-100 and concentrated to 100 μl by Amicon ultrafiltration. Aliquots of the concentrate (20 μl) were incubated without (*A*) or with (*B*) 2 μg ml^{-1} trypsin at 20 °C for 30 min, and the TCA-precipitable proteins were subjected to electrophoresis and autoradiography.



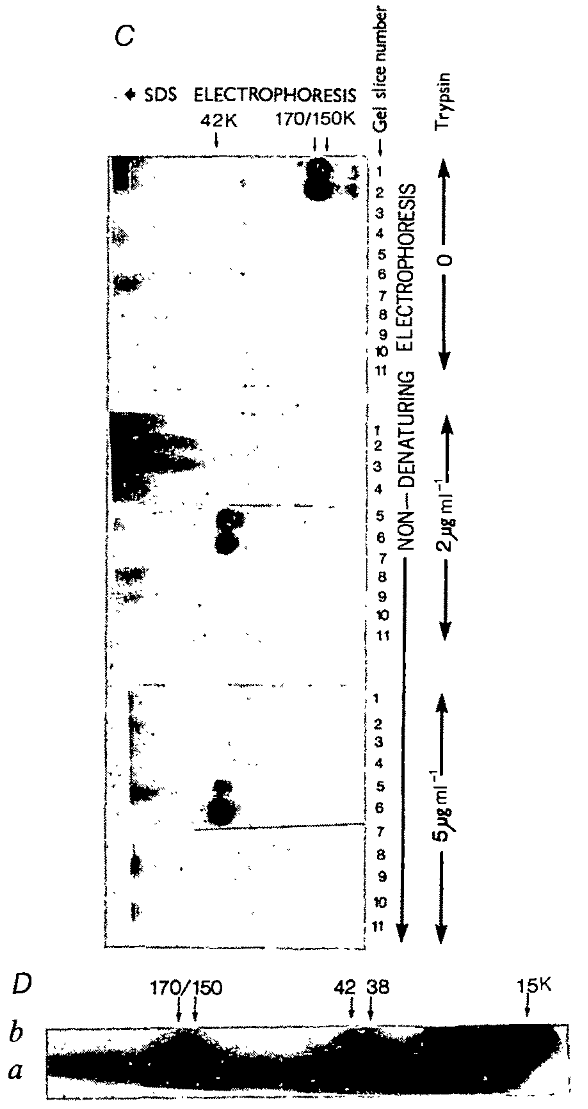


Fig. 3 Lack of effect of EGF on 42K peptide autophosphorylation. *A–F*, Crude Triton X-100 extracts of A431 membrane containing 0.1 pmol of receptor in 10 μl of 20 mM HEPES, 10% glycerol, 0.2% Triton X-100 were treated with different concentrations of trypsin at 20 °C for 30 min (lanes *A*, *B*: no trypsin; *C*, *D*: 3 μg ml^{-1} trypsin; *E*, *F*, *E'*, *F'*: 10 μg ml^{-1} trypsin). Action of trypsin was stopped with 1 μl of soybean trypsin inhibitor solution (10 mg ml^{-1}). The mixtures were incubated with (+) or without (–) 200 μM EGF at 20 °C for 10 min after which phosphorylation with 15 μM [γ-^{32}P]ATP and 1 mM $MnCl_2$ was allowed to proceed at 20 °C for 5 min. Lanes *E'* and *F'* represent longer autoradiographic exposures for the 10 μg ml^{-1} trypsin-treated crude extract samples. *G*, *H*, Purified receptor (0.1 pmol) treated with 5 μg ml^{-1} trypsin was incubated at 20 °C for 10 min either with (*H*) or without (*G*) 200 μM EGF, then phosphorylated with 15 μM[γ-^{32}*P*]ATP and 1 mM $MnCl_2$ at 20 °C for 5 min. TCA-precipitable radioactivity was subjected to electrophoresis and autoradiography.

containing phosphate acceptor domain of 15–20K. Further action of trypsin on the 150K peptide separates the kinase domain from the EGF-binding domain; a resultant 42K peptide retains both the kinase/ATP-binding site and the minor phosphate acceptor site and is catalytically functional. Note that similarly sized 30–45K phosphorylatable fragments have been described for $pp60^{src}$ and other oncogene kinase[19,20]. These findings and the recent demonstration of sequence homology between parts of the EGF receptor and the product of v-*erb-B*[21], suggest that some of the tyrosine kinase oncogene products may be generated by activation of the genomic segment encoding the kinase domain of EGF receptor. Also, there exists the possibility that such tyrosine kinases may be generated by cellular processing of the EGF receptor, resulting in a loss of the control normally exerted by EGF/ligand binding.

We thank Ms Laura Mattes for preparing A431 plasma membranes, and Drs Walter Englander and Charles Scher for reading the manuscript. This work was supported by NIH grants AM-25819 and HD-17896 and Research Career Development Award AM-00693 (to M.D).

PO Box 85800, San Diego, California 92138, USA

The receptor for epidermal growth factor (EGF) is a 170,000–180,000 molecular weight single-chain glycoprotein of 1,186 amino acids[1]. Its sequence suggests that it has an external EGF-binding domain, formed by the NH_2-terminal 621 amino acids, linked to a cytoplasmic region by a single membrane-spanning segment[1]. In the cytoplasmic portion, starting 50 residues from the membrane, there is a 250-residue stretch similar to the catalytic domain of the *src* gene family of retroviral tyrosine protein kinases[1], and, indeed, a tyrosine-specific protein kinase activity intrinsic to the receptor is stimulated when EGF is bound[2–5]. Increased tyrosine phosphorylation of cellular proteins, detected in A431 cells following EGF binding[6,7], may be important in the mitogenic signal pathway. Tumour promoters such as 12-*O*-tetradecanoyl-phorbol-13-acetate (TPA), counteract this increase[8,9], as well as causing loss of a high affinity class of EGF binding sites[9]. The major receptor for TPA has been identified as the serine/threonine-specific Ca^{2+}/phospholipid-dependent diacylglycerol-activated protein kinase, protein kinase C[10–14]. By substituting for diacylglycerol, TPA stimulates protein kinase C. Protein kinase C phosphorylates purified EGF receptor at specific sites, and this reduces EGF-stimulated tyrosine protein kinase activity[8]. TPA treatment of A431 cells increases serine and threonine phosphorylation of the EGF receptor at the same sites[8,15], which suggests that the reduction of EGF-receptor kinase activity in TPA-treated cells is a consequence of the receptor's phosphorylation by the kinase. We have attempted to identify these phosphorylation sites and show here that protein kinase C phosphorylates threonine 654 in the human EGF receptor. This threonine is in a very basic sequence nine residues from the cytoplasmic face of the plasma membrane in the region before the protein kinase domain; it is thus in a position to modulate signalling between this internal domain and the external EGF-binding domain.

Although treatment of A431 cells with TPA causes increased phosphorylation of the receptor on both threonine and serine residues, the only change detectable by tryptic peptide mapping is the appearance of three new phosphothreonine (PThr)-containing phosphopeptides, peptides X, Y and Z (Fig. 1), which are also the sites phosphorylated by protein kinase C *in vitro*[8]. We therefore concentrated on identifying these sites of threonine phosphorylation in the EGF receptor. Because the v-*erb-B* gene product is very similar to part of the EGF receptor[16], and reasoning that the phosphorylation sites would lie in the cytoplasmic region of the protein, we scanned the predicted v-*erb-B* protein sequence[17] for likely sites of threonine phosphorylation. Many protein kinases select their target amino acids through recognition of the primary sequence neighbouring the hydroxyamino acid, with positively or negatively charged amino acids being the key determinants in such sequences. Although it is not known whether protein kinase C is similar in this regard, it will phosphorylate many basic proteins *in vitro* such as histone H1, high mobility group (HMG) proteins and myelin basic protein[18–21]. We therefore focused on threonines with highly charged environments. Thr 98 of the predicted v-*erb-B* protein is contained in the sequence Arg-Arg-Arg-His-Ile-Val-Arg-Lys-Arg-Thr-Leu-Arg-Arg (Fig. 2); if it were phosphorylated, the limit tryptic digest of this sequence would yield the peptide PThr-Leu-Arg. Our experiments on separations of peptides on cellulose thin layers by electrophoresis and chromatography suggest that the mobility of this peptide would be very similar to that of peptide X in the EGF receptor. Peptide X is not susceptible to digestion by *Staphylococcus aureus* V8 protease (cleavage at Glu), *Pseudomonas fragi* protease (cleavage at Asp and cysteic acid) or chymotrypsin (cleavage at Phe, Tyr and Trp). We therefore synthesized the peptide PThr-Leu-Arg (Fig. 1). This peptide co-migrates precisely with peptide X in our standard two-dimensional separation conditions (Fig. 1); the complete predicted sequence of the human EGF receptor[1] shows that the sequence surrounding Thr 654 is identical to that in the equivalent region of the v-*erb-B* protein (Fig. 2). Because residues 654–656 are the only place in the EGF receptor from which Thr-Leu-Arg can be generated by trypsinolysis[1], peptide X must correspond to residues 654–656.

We next investigated peptides Y and Z. We suspected that they might be related to peptide X, as they were not susceptible to digestion by *S. aureus* V8 or *P. fragi* proteases or chymotrypsin, and their two-dimensional mobilities could be accounted for by the addition to peptide X of one and two extra basic residues respectively. The sequence embedding Thr 654 is likely to give rise to products with additional basic residues at either terminus of the limit digest peptide due to the inability of trypsin to act as an exopeptidase. To test whether all three peptides indeed form a nested set, we synthesized a 24 amino acid peptide corresponding to residues 87–110 of the predicted v-*erb-B* protein (this is identical to the sequence of the EGF receptor between residues 643 and 666 except for the first two residues, and contains one threonine and no serines). This peptide is phosphorylated *in vitro* by a purified preparation of protein kinase C (Fig. 3*a*). The only detectable phosphoamino acid in the resultant labelled phosphopeptide is PThr (Fig. 3*b*). Two-

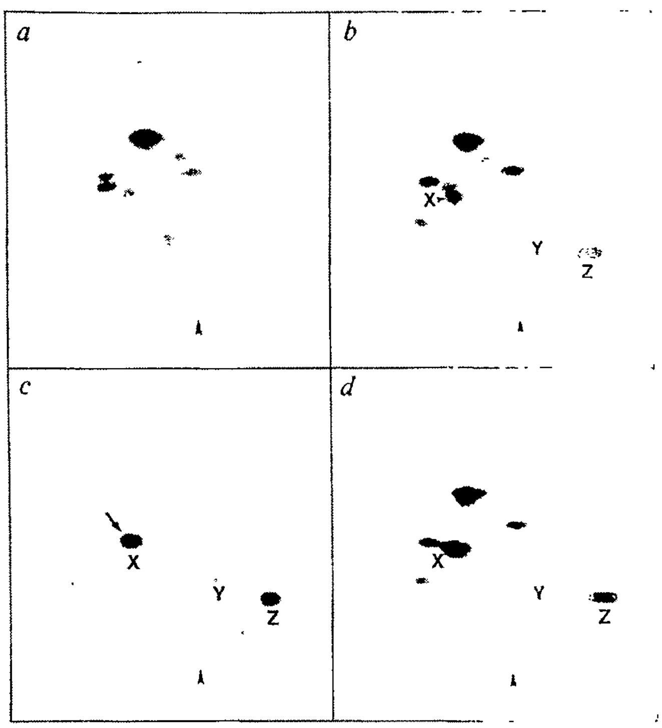

Fig. 1 Tryptic phosphopeptides of A431 cell EGF receptor and synthetic v-*erb-B* peptide. *a*, 700 Cerenkov c.p.m. tryptic digest of ^{32}P-labelled EGF receptor from untreated A431 cells (72 h). *b*, 900 Cerenkov c.p.m. tryptic digest of ^{32}P-labelled EGF receptor from TPA-treated A431 cells together with 1 μg PThr-Leu-Arg (72 h). *c*, 1,000 Cerenkov c.p.m. tryptic digest of ^{32}P-labelled phosphorylated synthetic peptide with 1 μg PThr-Leu-Arg (24 h). *d*, 900 Cerenkov c.p.m. tryptic digest of ^{32}P-labelled EGF receptor from TPA-treated A431 cells plus 400 Cerenkov c.p.m. tryptic digest of ^{32}P-labelled phosphorylated synthetic peptide (72 h). The positions of peptides X, Y and Z previously shown to be phosphorylated by protein kinase C are indicated. PThr-Leu-Arg, where present, was detected by staining with ninhydrin. Its position is given by a diagonal arrow on panel *c*, while in panel *b* it migrates with the spot arrowed X. **Methods:** Two subconfluent 5-cm dishes of A431 cells were labelled with 1 mCi ^{32}P-orthophosphate for 16 h, then one culture was treated with 100 ng ml^{-1} TPA dissolved in dimethyl sulphoxide for 60 min and the other with an equivalent amount of dimethyl sulphoxide before isolation of the EGF receptor by immunoprecipitation as described previously[8]. Tryptic peptides were prepared from ^{32}P-labelled EGF receptor as outlined previously[30]. The peptide Tyr-Leu-Arg-Arg-Arg-His-Ile-Val-Arg-Lys-Arg-Thr-Leu-Arg-Arg-Leu-Leu-Gln-Glu-Arg-Glu-Leu-Val-Glu-NH_2 was synthesized using a Beckman 990 synthesizer and purified by ion exchange and partition chromatography. The peptide was homogeneous on HPLC analysis and had the expected amino acid composition. This peptide was phosphorylated by protein kinase C as follows. Peptide at a final concentration of 0.2 mM was incubated at 30 °C for 10 min in 20 μl of a buffer containing 20 mM HEPES, *p*H 7.4, 10 mM $MgCl_2$, 0.5 mM $CaCl_2$, 5 mM dithiothreitol, 60 μg ml^{-1} phosphatidylserine and 6 μg ml^{-1} diolein together with 10 μCi [γ-^{32}P]ATP (3,000 Ci mmol^{-1}, Amersham) and 0.05 units kinase C purified from rat brain by a modification of the procedure of Kikkawa *et al.*[31] including DE52 cellulose chromatography, Ultragel ACA 34 filtration and hydroxyapatite chromatography steps. The protein kinase C preparation had a specific activity of ~150 U mg^{-1} at 22 °C using histone HI as substrate. The phosphorylated peptide was isolated by electrophoresis for 35 min at 1 kV on a 100-μm cellulose thin layer plate. 3×10^5 Cerenkov c.p.m. of peptide were recovered following elution and 10^4 c.p.m. digested with 2 μg trypsin in 10 μl 0.025 M NH_4HCO_3 for 2 h at 37 °C. The peptide PThr-Leu-Arg was synthesized as follows. tBOC-phosphothreonine was prepared by treatment of 100 μmoles D,L-phosphothreonine (Sigma) with 200 μmoles tBOC-azide (Aldrich) in 500 μl water/dimethylformamide/pyridine (25:25:1) for 24 h at 23 °C. The tBOC-PThr was recovered by stepwise elution from DE52 cellulose with ammonium acetate *p*H 4.5. tBOC-PThr, which eluted at 0.5 M, was desalted following lyophilization by gel filtration on Sephadex G-15 in water (yield of free acid 10%). 6 μmoles tBOC-PThr were coupled to 6 μmoles Leu-Arg (Bachem) in water (*p*H adjusted to 5.0) with 10 μmoles 1-ethyl-3(3-dimethylamino propyl)carbodiimide (Calbiochem-Behring) for 16 h at 23 °C. Following deblocking with trifluoroacetic acid for 30 min at 23 °C, the major product was separated from PThr and Leu-Arg by electrophoresis at *p*H 4.7 for 30 min at 1 kV on a 100-μm cellulose thin layer plate (yield 5%). This peptide contained phosphate and had the expected amino acid composition. The resultant samples were analysed on a 100-μm cellulose thin layer plate by electrophoresis at *p*H 8.9 for 20 min at 1 kV (horizontal dimension, with a centre origin (arrowhead) and anode to the left) and chromatography (vertical dimension)[30]. Exposure times are measured with an intensifying screen at −70 °C.

Fig. 2 Schematic diagram showing the site of protein kinase C phosphorylation in the EGF receptor. The receptor is depicted as a bar, with amino acid numbers given above taken from the sequence of Ullrich *et al.*[1]. The proposed transmembrane domain is filled, while the protein kinase domain is hatched. The sequence of the human EGF receptor from residues 643 to 666 is shown with the homologous sequence from the v-*erb-B* gene product aligned below[1,17]. The v-*erb-B* sequence shown is that of the synthetic peptide used in Figs 1 and 3. The two residues at the cytoplasmic end of the proposed transmembrane domain are boxed at the left-hand side of these sequences. Note that the EGF receptor and v-*erb-B* sequences differ only in these two residues. Potential sites of trypsin cleavage are marked as diamonds between the two sequences. The heavy bars below the sequences indicate the deduced structures of peptides X, Y and Z.

dimensional separation of a tryptic digest of this phosphopeptide shows three peptides with mobilities very similar to peptides X, Y and Z, which co-migrate with those peptides on analysis of a suitable mixture (Fig. 1).

The precise structures of peptides Y and Z were determined by Edman degradation of ^{32}P-labelled peptides obtained from a digest of the phosphorylated synthetic peptide. After each cycle, a fraction of the sample was analysed by electrophoresis, without removal of the cleaved NH_2-terminal residue. All the radioactivity is released from peptide X at cycle 1 as expected (Fig. 3*c*), but the majority of the radioactivity is not released from peptide Y until cycle 2 (not shown). Sequential cycles convert peptide Z to peptide Y and then to peptide X (Fig. 3*c*) Prolonged digestion of peptide Z with a vast excess of trypsin also converts it inefficiently into peptide X (not shown). We therefore deduce that the structures of peptides Y and Z are Arg-PThr-Leu-Arg and Lys-Arg-PThr-Leu-Arg respectively.

The phosphorylation of the synthetic v-*erb-B* peptide by protein kinase C requires both Ca^{2+} and phospholipid (not shown). The K_m for peptide in this reaction was approximately 5 µM and the V_{max} 5 µmol per min per mg (Fig. 3*a*). This high affinity suggests that protein kinase C recognizes predominantly primary sequence determinants in its substrates. The sequence in the EGF receptor is the first described for a site phosphorylated by protein kinase C *in vivo*. It will be possible to produce synthetic variants of this sequence to identify residues which are important for recognition by the kinase. In myelin basic protein, the site has features similar to that in the EGF receptor, with basic residues at positions two and eight to the NH_2-terminal side of the phosphorylated Ser 115 (ref. 22). A synthetic peptide based on this sequence serves as a good substrate for protein kinase C (R. S. Turner, J. F. Kuo and B. E. Kemp, personal communication). Similarly, Ser 24 phosphorylated in HMG 17 is preceded by basic residues at positions 1, 2, 7 and 9 (ref. 21), and Ser 35 phosphorylated in histone H1 by basic residues at positions 2, 3, 4, 8 and 9 (ref. 18). Thus, protein kinase C appears to belong to the growing number of protein kinases which favour basic residues in the vicinity of their substrate hydroxyamino acid. These include the cyclic AMP- and cyclic GMP-dependent protein kinases, myosin light-chain kinase, phosphorylase kinase and the multi-functional calmodulin-dependent protein kinase.

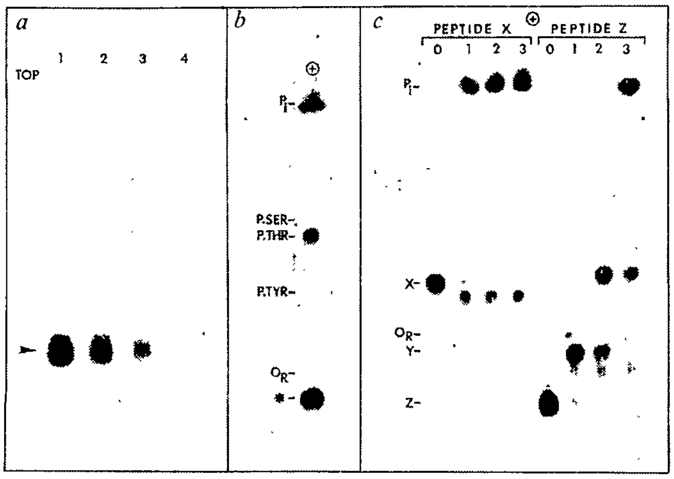

Fig. 3 Phosphorylation of synthetic peptide. ***a***, Synthetic peptide at the following concentrations was phosphorylated as described in Fig. 1 legend except that the final concentration of $[\gamma\text{-}^{32}\text{P}]$ATP was 10 µM (specific activity 10 µCi $nmol^{-1}$) and the incubation time at 30 °C was 4 min: lane 1, 3.0 µM; lane 2, 1.5 µM; lane 3, 0.75 µM; lane 4, no peptide. The reactions were stopped by the addition of EGTA to 2 mM and freezing. One µl of each sample was analysed by SDS-polyacrylamide electrophoresis on a gel containing 25% acrylamide, 0.05% bisacrylamide. The dried gel was exposed to X-ray film for 2 h. The arrowhead indicates the position of the phosphorylated peptide which co-migrated with marker glucagon (3,500 molecular weight). The band in lane 1 contained 1.7×10^3 Cerenkov c.p.m. ***b***, ^{32}P-labelled synthetic peptide (1,500 Cerenkov c.p.m.) was hydrolysed in 6 M HCl for 1 h at 110 °C and then analysed by electrophoresis at *p*H 3.5 (origin indicated O_R, anode at top) on a 100-µm cellulose thin layer plate for 30 min at 1 kV with internal phosphoamino acid standards. The plate was exposed to X-ray film for 12 h at −70 °C with an intensifying screen. The positions of the marker phosphoserine (P.SER), phosphothreonine (P.THR) and phosphotyrosine (P.TYR) detected by staining with ninhydrin are given. Also indicated are the positions of orthophosphate (P_i) and a phosphopeptide (*) which was identified as PThr-Leu by co-migration with synthetic PThr-Leu. ***c***, Purified ^{32}P-labelled peptides X and Z (7,000 and 13,000 Cerenkov c.p.m. respectively) were taken through three cycles of Edman degradation as follows. Peptides were dissolved in 40 µl pyridine/water (50:50) containing 5% phenylisothiocyanate and incubated at 45 °C for 30 min. The reactions were then extracted twice with 200 µl heptane/ethyl acetate (10:1) and twice with 200 µl heptane/ethyl acetate (2:1). The organic phases were discarded and the aqueous phases were lyophilized. The residues were taken up in 50 µl trifluoroacetic acid and incubated at 45 °C for 10 min to cleave the NH_2-terminal amino acid from the peptide. The trifluoroacetic acid was removed *in vacuo* and the residues were dissolved in 20 µl H_2O. Five µl were sampled and the remainder was taken through two further cycles in identical fashion with the equivalent of one-quarter of the original material being sampled at each stage. One-third of the samples from each cycle and an equivalent amount of untreated peptide were analysed by electrophoresis at *p*H 8.9 (origin indicated O_R, anode at top) for 20 min at 1 kV on a 100-µm cellulose thin-layer plate. The plate was exposed to X-ray film for 12 h at −70 °C with an intensifying screen. The positions of peptides X, Y and Z and orthophosphate (P_i) are indicated. Lane 0, starting material; lane 1, sample after first cycle; lane 2, sample after second cycle; lane 3, sample after third cycle. The acid-catalysed cyclization reaction of a phenylisothiocyanate-reacted peptide possessing an NH_2-terminal phosphothreonine or phosphoserine leads to the elimination of much of the phosphate during the cleavage rather than the formation of an anilinothiazolinone derivative. The minor spot migrating just below the position of peptide X may be anilinothiazolinone phosphothreonine. Note that the analysis of this type of experiment will be more complicated if the peptide contains a group reactive with phenylisothiocyanate in addition to the α-NH_2 group.

Very little is known about physiological substrates for protein kinase C. TPA-induced serotonin release from platelets correlates well with protein kinase C-mediated phosphorylation of a 40,000 molecular weight protein[23]. The EGF receptor, however, is the first example where phosphorylation by protein kinase C of a purified protein has been shown to have a functional consequence. The normal role of the protein kinase C-mediated phosphorylation of the receptor may be to act as a feedback mechanism to attenuate the response to EGF either by blocking kinase activation or by decreasing EGF binding affinity[9]. The feedback would be modulated via diacylglycerol whose concentration rises as a result of EGF-induced turnover of phosphatidylinositol[24]. This is in agreement with the increased phosphorylation of the receptor at the protein kinase C-specific sites in EGF-treated A431 cells[15].

We have shown here that there is a single major threonine phosphorylation site for protein kinase C in the EGF receptor at position 654. Our previous measurements indicate that up to 35% of receptor molecules are phosphorylated at this threonine in response to either phorbol ester or indole alkaloid tumour promoters[8]. The active form of kinase C is largely membrane associated, where it is bound to phospholipids and either its natural activator diacylglycerol or a substitute activator such as TPA[25]. The position of Thr 654 spaced nine amino acids from the cytoplasmic side of the proposed membrane-spanning segment puts it in an ideal position to be phosphorylated by protein kinase C. The 50 residues between the membrane and the start of recognizable homology with the tyrosine protein kinases may act as a 'linker' between the EGF-binding domain and the protein kinase domain, and as such might be involved in signal transmission between the two upon EGF binding.

It is not known how the binding of EGF increases the activity of the receptor tyrosine protein kinase. There could be a direct allosteric conformational change induced by EGF binding, although it is unclear how this might be transmitted across the membrane. Alternatively EGF-dependent clustering of the receptor may be required for activation. Because the basic residues in the 'linker' are likely to interact with the phosphate head groups of plasma membrane phospholipids, the introduction of a phosphate group in this region with its potential as an alternative charge acceptor could well have significant effects on both tyrosine protein kinase activity and EGF binding, whatever mechanism is involved. Our results suggest that alteration of Thr 654 or neighbouring residues by site-directed mutagenesis and the use of antibodies recognizing this region may further our understanding of signal transduction.

As TPA markedly reduces EGF binding to many mitogenically responsive cell types[26-29], it is of interest to determine whether protein kinase C mediates threonine phosphorylation of the EGF receptor in such cell types in a manner similar to A431 cells. An investigation of whether v-*erb-B* proteins are phosphorylated at the equivalent site also seems warranted.

We thank Jill Meisenhelder for her help, our colleagues for their encouragement and Gordon Gill for the preparation of kinase C used in these studies. This work was supported by USPHS grants CA-17096, CA-28485, HD-09096 and AM-18811 from the NIH.

Autophosphorylation sites on the epidermal growth factor receptor

J. Downward, P. Parker & M. D. Waterfield

Department of Protein Chemistry, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX, UK

The epidermal growth factor (EGF) receptor is a tyrosine-specific protein kinase with autophosphorylating activity[1–4]. A 300 amino acid-long region of the receptor's cytoplasmic domain matches (35–90 % homology) sequences of transforming proteins from the *src* family[5] and includes a putative nucleotide binding site[6]. Several of the *src* transforming proteins have tyrosine kinase activity[7], but v-*erb-B*, which appears to be a truncated EGF receptor, is virtually identical to the receptor over this region and yet lacks detectable kinase activity[8,9]. To locate possible acceptor sites in the v-*erb-B* protein, we have mapped these sites in the human EGF receptor. We report here that three tyrosine sites near the C-terminus are phosphorylated *in vitro*. In intact cells, we find that EGF stimulates phosphorylation of several sites, the tyrosine 14 residues from the C-terminus being modified the most extensively. The equivalent site is absent in the v-*erb-B* protein of avian erythroblastosis virus (AEV) and may influence tyrosine kinase activity[10,11].

Knowledge of the complete primary structure of the human HEGF receptor[5] is used here to map the tyrosine acceptor sites for the receptor kinase autophosphorylation activity. We purified EGF receptors from detergent lysates of A431 cells using R1 monoclonal immunoaffinity chromatography and performed *in vitro* autophosphorylation by addition of [γ-^{32}P]ATP to immobilized receptor while in an immune complex[12] in the presence or absence of EGF (Fig. 1). After tryptic digestion of the receptor, peptides were resolved by reverse-phase HPLC. We found that phosphate-labelled peptides (P1, P2 and P3; Fig. 1*a*) eluted at three distinct acetonitrile concentrations as reported previously[13]. The most hydrophobic peptide, P3, was partially resolved into two components, a and b. Thin-layer electrophoretic analysis of acid hydrolysates[14] from either receptor or purified peptides demonstrated that tyrosine was the only amino acid phosphorylated *in vitro* in the conditions used. Only the rate of phosphorylation seemed to be altered by EGF, because identical peptides were phosphorylated in its presence or absence over longer incubation times (Fig. 1*b*).

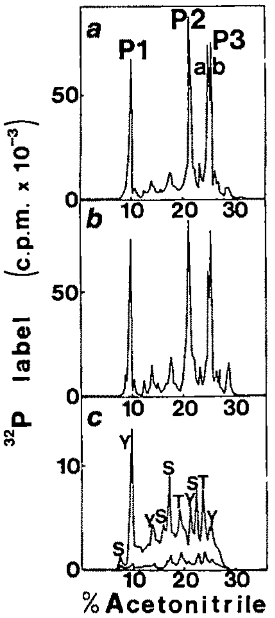

Fig. 1 Tryptic phosphopeptide maps of EGF receptor from A431 cells. ***a***, EGF receptor was purified from A431 cells as described previously[12]. Autophosphorylation was performed with 150 μg receptor as washed immunocomplex with monoclonal antibody R1–Sepharose. The receptor was incubated for 1 h at 20 °C in 1 μg ml^{-1} EGF, 150 mM NaCl, 1 mM MnCl$_2$, 50 mM HEPES *p*H 7.4, 0.1 % Triton X-100. [γ-^{32}P]ATP was then added (20 μM, specific activity 690 c.p.m. pmol^{-1}) for 10 min. Reagents were then removed by filtration and the receptor washed, eluted, fully reduced and alkylated, further purified by gel permeation chromatography, digested with trypsin and run on reverse-phase HPLC at *p*H 2.0, all as described previously[12]. Fractions (0.3 ml) were collected at a flow rate of 1.5 ml min^{-1} and a gradient of 1 % acetonitrile min^{-1}. The ^{32}P-phosphate label in each fraction was determined by counting Cerenkov radiation and is plotted against the percentage acetonitrile in the fraction. ***b***, Same as *a* except that autophosphorylation was performed in the absence of EGF (replaced by 1 μg ml^{-1} bovine serum albumin, BSA). The length of the incubation in the presence of [γ-^{32}P]ATP was increased to 60 min. ***c***, Two subconfluent 15-cm dishes of A431 cells were labelled for 14 h, each with 5 mCi ^{32}P-orthophosphate in Eagle's medium containing 5 % normal phosphate concentration and 0.5 % fetal calf serum. Upper line, 1 μg ml^{-1} EGF was added to one dish for 10 min before lysis in 100 mM HEPES *p*H 8.5, 50 mM NaF, 1 mg ml^{-1} BSA, 1 mM Na$_3$VO$_4$, 10 mM NaP$_i$ *p*H 8.5, 5 mM *p*-nitrophenylphosphate, 100 mM NaCl, 1 mM EGTA, 1 % Triton X-100, 10 mM benzamidine, 50 μg ml^{-1} phenylmethylsulphonyl fluoride, 10 μg ml^{-1} soybean trypsin inhibitor. Kinase activities were inhibited by chelation of divalent metal ions. The extract was clarified by centrifugation, then 50 μg of R1–Sepharose added for 90 min at 4 °C. The immobilized antibody was washed thoroughly and receptor eluted as described[12]. The *in vivo* labelled receptor was then mixed with 150 μg of unlabelled purified EGF receptor as a carrier and processed as described in *a*. The phosphoamino acid content of each peak was determined by partial acid hydrolysis and thin-layer electrophoresis[14]; the predominant phosphoamino acid is given above each peak. Lower line, the second dish was processed as above except the cells were not treated with EGF before lysis (replaced by 1 μg ml^{-1} BSA). Both dishes had the same cell density before labelling. The amount of receptor immunoprecipitated was the same from each plate as determined by Coomassie blue staining of SDS-polyacrylamide gels.

To characterize the kinase autophosphorylation sites used *in vivo*, we labelled A431 cells with ^{32}P-phosphate (Fig. 1). We fractionated tryptic phosphopeptides by HPLC and determined the phosphorylated amino acids by thin-layer electrophoresis[14]. Ten distinct phosphopeptides were found, four containing phosphotyrosine, four phosphoserine and two phosphothreonine. In previous reports, fewer phosphopeptides were detected[15]. Three

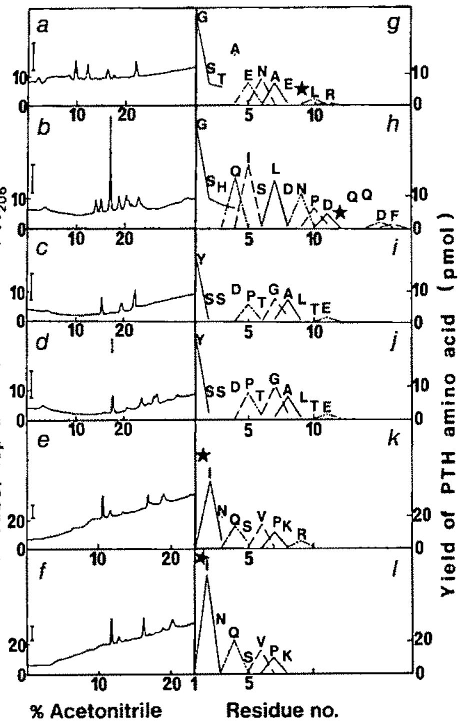

Fig. 2 Purification and sequencing of phosphopeptides. *a*, The fractions labelled Pl in Fig. 1*a* were pooled and applied to a Synchropak RPC 18 reverse-phase HPLC column (4.6×75 mm; Synchrom, Linden, Indiana) run in 10 mM ammonium acetate buffer at *p*H 6.5 with a linear gradient of acetonitrile of 1 % min^{-1} at 1.5 ml min^{-1}. Fractions (0.3 ml) were collected and counted for Cerenkov radiation. The absorbance of the eluate at 206 nm was monitored (the bar represents 0.01 absorbance units). 310 pmol of labelled phosphate were loaded onto the column. *b*, The fractions HHlabelled P2 in Fig. 1*a* were run as described above for *a*; 360 pmol were loaded. *c*, Fractions labelled P3a in Fig. 1*a* were run as in *a*; 220 pmol were loaded. *d*, Fractions labelled P3b in Fig. 1*a* were run as in *a*; 270 pmol were loaded. *e*, The fractions corresponding to P3a from a second identical preparation of *in vitro* labelled EGF receptor were digested with *Staphylococcus aureus* V8 protease (1 μg in 10 μl in 50 mM ammonium bicarbonate, *p*H 7.5 for 24 h at 37 °C). The resulting mixture of peptides was separated by reverse-phase HPLC at *p*H 2.0 (ref. 12). Fractions (0.3 ml) were collected. The linear gradient was 0.5% acetonitrile min^{-1}. The bar represents 0.01 absorbance units. *f*, The fractions corresponding to P3b were digested and separated as in *e*. *g*, The fractions containing the peak of phosphate label from *a* were pooled; the 70 pmol of phosphate label present were divided into two halves which were sequenced on gas phase sequencers[21,22]. The yield of PTH amino acid (identified above the peak by the one-letter code) is plotted against cycle number of the Edman degradation. *h*, Sequence of the phosphopeptide from *b*; 45 pmol of phosphate label were loaded for each sequencer run. *i*, Sequence of phosphopeptide from *c*; 25 pmol phosphate label loaded. *j*, Sequence of phosphopeptide from *d*; 30 pmol phosphate label loaded. *k*, Sequence of phosphopeptide from *e*; 85 pmol phosphate label loaded. *l*, Sequence of phosphopeptide from *f*; 105 pmol phosphate label loaded. * Phosphotyrosine residues.

Fig. 3 The alignment of the phosphate acceptor regions of the EGF receptor with the v-*erb-B* protein sequence. (Sequence of the EGF receptor from ref. 5, sequence of the v-*erb-B* protein from AEV-H, from ref. 10.) The tyrosine residue at 845 (○) in the EGF receptor sequence is homologous to the pp60$^{v\text{-}src}$ phosphoacceptor site[19]. ●, EGF receptor phosphorylation sites P1, P2 and P3; △, acidic residues at phosphorylation sites. The peptide sequences determined in Fig. 2 are overlined, the predicted complete sequence of each tryptic phosphopeptide is underlined. The last four residues of the v-*erb-B* protein are derived from the viral *env* gene[10].

of the four phosphotyrosine peptides co-chromatograph at two different *p*Hs with peptides P1, P2 and P3 (data not shown). Addition of EGF to intact cells caused a general increase (5-fold) in the extent of receptor phosphorylation with a marked selective increase (10-fold) in the extent of labelling of peptide P1 (Fig. 1*c*). This is a considerably larger stimulation than that reported previously, which may be due to the use of protease inhibitors that prevented loss of sites near the C-terminus.

To locate the phosphorylation sites, pmol amounts of phosphate-labelled peptides were purified[12] and sequenced[16,17] (Fig. 2). In each case we located our established sequence in the amino acid sequence of the EGF receptor (Fig. 3). At the ninth degradation cycle of P1, we recovered no phenylthiohydantoin (PTH) amino acid although the cDNA sequence predicted a tyrosine residue. In gas phase sequencing, phosphotyrosine PTH cannot be detected[18]. Because we knew that the phosphate in this peptide occurs in phosphotyrosine and that the peptide only contains one tyrosine residue, the phosphate could be assigned unequivocally to residue nine. Similarly, we assigned residue 12 as phosphotyrosine in P2. Peptides P3a and P3b gave the same sequence up to residue 11; however, none of the residues assigned was a phosphotyrosine that was presumably carboxy-terminal to this sequence. We digested peptides P3a and P3b with *Staphylococcus aureus* V8 protease and purified (Fig. 2*e*, *f*) and sequenced (Fig. 2*k*, *l*) the resulting phosphopeptides. P3a had an additional C-terminal arginine residue compared with P3b and the N-termini could be assigned as phosphotyrosine.

Thus the major *in vitro* autophosphorylation sites of the EGF receptor are assigned as follows: P3, tyrosine 1,068; P2, tyrosine 1,148; and P1, tyrosine 1,173. Each of these residues is immediately preceded by an amino acid residue with an acidic side chain. These sequences are similar to most of the tyrosine phosphorylation sites described previously[19,20]. Tyrosine 1,173 is the site selectively phosphorylated *in vivo* while tyrosines 1,148 and 1,068 are autophosphorylation sites used to a lesser extent *in vivo*. A third minor *in vivo* tyrosine autophosphorylated peptide has not yet been located. The major autophosphorylation site that is selectively phosphorylated *in vivo* (P1) is 14 residues from the carboxy-terminus of the EGF receptor and is not found in the v-*erb-B* protein from the *erb-B* gene of AEV (AEV-H) which is fused at the carboxy-terminus to four residues of the viral *env* protein (Fig. 3)[10]. Therefore, v-*erb-B* is probably terminated prematurely with respect to the cellular sequences from which it is derived. P1 has the same neighbouring V8 protease and trypsin cleavage sites as predicted for the major *in vivo* autophosphorylation site of the EGF receptor[21]. The autophosphorylation sites P1, P2 and P3 used *in vitro* do not correspond to the tyrosine phosphorylated in one member of the *src* family, pp60$^{v\text{-}src}$ (ref. 19), which would be tyrosine 845 in the EGF receptor. These sites are not shared with any other members of the *src* family of oncogene products except v-*erb-B*.

The absence of the site homologous to P1 in the v-*erb-B* protein may contribute to the failure to detect kinase autophosphorylation activity in AEV-transformed cells. C-terminal truncation can influence tumorigenicity since the deletion mutant AEV-H, td-130, which has a large C-terminal truncation, will induce sarcomas but not erythroblastosis in chickens[10]. On the other hand, avian leukosis virus can induce erythroblastosis by insertion of a viral long terminal repeat into c-*erb-B* with consequent N-terminal trunction but presumably without affecting the C-terminus of the protein product[22]. As yet the significance of EGF receptor tyrosine autophosphorylaton is unclear despite work performed on two other members of the *src* family, pp60$^{v\text{-}src}$ (ref. 23) and p130$^{gag\text{-}fps}$ (ref. 24); it remains to be seen if either or both amino- and carboxy-terminal truncations of the receptor are essential for generation of a transforming signal.

Isolation of the closed circular form of the transposable element Tc*1* in *Caenorhabditis elegans*

A. M. Rose* & T. P. Snutch†

* Department of Medical Genetics, University of British Columbia, Vancouver, Canada V6T 1W5
† Department of Biological Sciences, Simon Fraser University, Burnaby, Canada V5A 1S6

The mobilization of Tc*1*, a transposable element in the genome of the roundworm *Caenorhabditis elegans*, has been investigated. Genomic blot hybridization has shown that Tc*1* exists in very different numbers in the genomes of two closely related strains of *C. elegans*[1,2]: there are ~30 copies of Tc*1* in the Bristol strain, whereas in the Bergerac strain there are 200–300. Most of these Tc*1* elements are structurally highly conserved[1–3] although there exists a second form which contains a *Hin*dIII restriction site (Tc*1* (*Hin*) form) and comprises ~10% of the population[4]. Excision of Tc*1* from its chromosomal location in the Bergerac strain is indicated by the presence, on genomic blots, of a minor band corresponding to the size of the uninserted restriction fragment[1,5,6]. Here we describe the recovery of extrachromosomal linear and closed circular copies of Tc*1* from the Bergerac strain, presumably a result of Tc*1* excision.

We initially looked for a Tc*1* transcription product using Northern blots containing RNA isolated from two strains of *C. elegans*. RNA preparations from the Bergerac strain contained Tc*1*-hybridizing sequences (Fig. 1). Attempts to demonstrate that the Tc*1*-hybridizing material was RNA revealed that this material was resistant to alkali hydrolysis and ribonuclease digestion, but sensitive to restriction enzyme digestion. These results indicated that extrachromosomal copies of Tc*1* had co-precipitated with RNA in the extraction conditions used here[7]. The Tc*1*-hybridizing material was observed in the Bergerac strain, but not in the Bristol strain, although the methods used would probably not have detected the 10-fold lower levels that would be expected in the Bristol strain. Some Tc*1*s from the Bristol strain have been cloned and found to have restriction maps identical to those isolated from the Bergerac strain, indicating that they are potentially functional elements (N. Mawji, unpublished results). The presence of extrachromosomal Tc*1* is not limited to the Bergerac strain; it has also been detected in other wild-type and laboratory strains of *C. elegans* (data not shown).

To investigate the Tc*1*-hybridizing material further, DNA was isolated by CsCl–ethidium bromide ultracentrifugation from the Bergerac strain. Individual fractions were collected from the gradient, electrophoresed on agarose gels, blotted onto nitrocellulose, and tested for the presence of Tc*1*-hybridizing material (Fig. 2). A large amount of Tc*1*-hybridizing material is present in the fractions corresponding to the genomic DNA. This material presumably represents the 300 or so copies of Tc*1* that are integrated throughout the genome. There is also a band in the region of the gradient which corresponds to linear copies of extrachromosomal Tc*1* (fractions 3, 4). Below the main genomic band on the gradient, a minor band containing Tc*1*-hybridizing material was detected in fractions 5 and 6. Restriction digestion was used to demonstrate that the material in fractions 5 and 6 is in fact closed circular Tc*1*.

The Tc*1*-hybridizing material in fractions 5 and 6 from the CsCl gradient, corresponding to a linear fragment of 950 base pairs (bp), was purified on an agarose gel and analysed by gel electrophoresis. In the undigested sample, two bands of Tc*1*-hybridizing material were apparent (Fig. 3, lane 1). The major band has an apparent size of 950 bp, consistent with its being a closed circular molecule the size of Tc*1* (1,610 bp). The minor band presumably consists of nicked circles that were generated after isolation of the closed circular material from the gradient fractions. When digested with *Cla*I, an enzyme that has a single cleavage site in Tc*1*, a single band of ~1,600 bp is observed (data not shown). When digested with *Xho*I, a band of ~1,400 bp is observed (Fig. 3, lane 2). *Xho*I digests Tc*1* at two

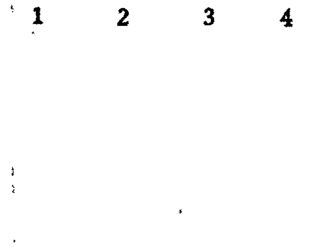

Fig. 1 Autoradiograph of Tc*1*-hybridizing material detected in RNA preparations: lanes 1, 2, Bristol strain; lanes 3, 4, Bergerac strain.

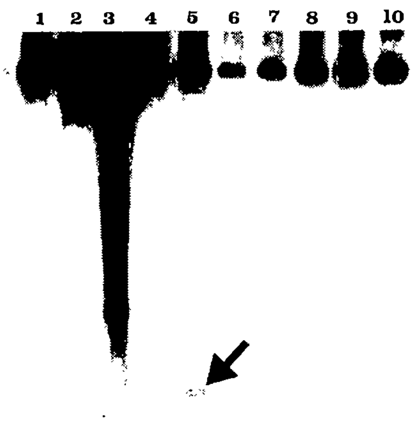

Fig. 2 Isolation of extrachromosomal closed circular and linear copies of Tc*1*. Bergerac DNA was prepared[1] and centrifuged on a CsCl-ethidium bromide equilibrium gradient[5]. Fractions were collected and the DNA recovered and electrophoresed on a 0·8% agarose gel. DNA was transferred to nitrocellulose[9] and hybridized with ^{32}P-labelled Tc*1* (*Hin*) DNA. Filters were hybridized overnight and autoradiographed for 5 days using Kodak Blue Brand film. Lane numbers correspond to CsCl gradient fraction numbers. The arrow indicates the closed circular Tc*1*.

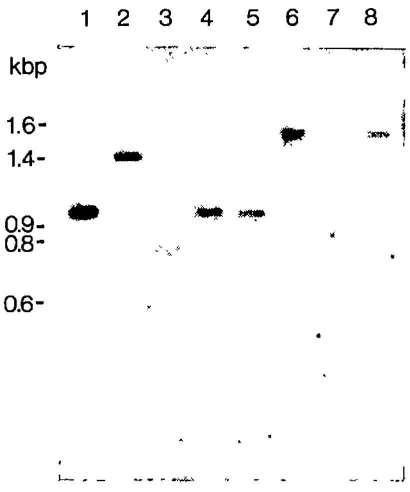

Fig. 3 Autoradiograph of restriction digests of the extrachromosomal Tc*1*-hybridizing material. Before digestion, the extrachromosomal Tc*1* from the CsCl fractions was further purified to remove the high-level contamination of chromosomal Tc*1* seen in Fig. 2. Agarose gel fractions corresponding to sizes of either 1,610 bp (linear) or 950 bp (closed circular) were electroeluted and electrophoresed in a 0.8% agarose gel. Lane 1, undigested material from CsCl fractions 5 and 6. Lanes 2-5, restriction digests of this material: *Xho*I (lane 2); *Hin*fI (lane 3); *Hin*dIII (lane 4); *Eco*RI (lane 5). Lane 6, undigested material from CsCl fraction 3. Lanes 7, 8, restriction digests of this material with *Xho*I and *Eco*RI, respectively. The sizes of the fragments are indicated at the left-hand side in kilobase pairs (kbp).

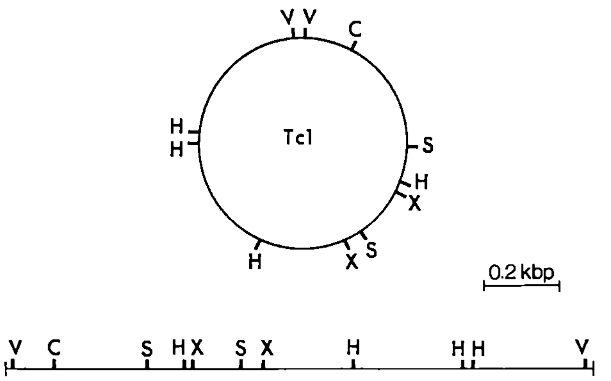

Fig. 4 Restriction map of closed circular and linear Tc*1*: V, *Eco*RV; X, *Xho*I; H, *Hin*fI; S, *Sal*I. Tc*1* lacks *Eco*RI and *Hin*dIII sites.

sites, 220 bp apart, thus a *Xho*I digest of a linear Tc*1* molecule would give three fragments of 890, 500 and 220 bp. The observed fragment of 1,400 bp is predicted for a circular molecule closed at the inverted repeats. The enzyme *Eco*RV, which cuts once in each of these inverted repeats, shifts the size from 950 bp to just under 1,600 bp as predicted (data not shown). Digestions with other restriction enzymes also generated fragments of the sizes predicted assuming a closed circular Tc*1* molecule was being digested (Fig. 3). No *Eco*RI or *Hin*dIII sites could be detected in the extrachromosomal material (lanes 4 and 5), as expected from the published restriction maps of Tc*1* (refs 1, 3). If the Tc*1* (*Hin*) form[4] was present in proportion to its chromosomal representation, ~10% of the molecules would be expected to linearize with *Hin*dIII.

Lane 6 of Fig. 3 contains material of 1,600 bp from fraction 3 of the CsCl gradient that had been purified on an agarose gel, and corresponds to linear copies of extrachromosomal Tc*1*. Restriction digestion of this material with *Xho*I gave a 890-bp fragment (lane 7); a fragment of this size is predicted if the DNA contains linear molecules of Tc*1* with unique ends at the inverted repeats (see above and restriction maps of linear and closed circular Tc*1* shown in Fig. 4). The large number of linear molecules detected is intriguing, but their significance to Tc*1* transposition is unclear.

We have demonstrated the recovery of extrachromosomal copies of Tc*1* from the Bergerac strain of *C. elegans*. High-frequency excision of Tc*1* from somatic tissue has been demonstrated previously[6] and is presumably the source of the extrachromosomal linear and closed circular Tc*1*s demonstrated here. At present we have no evidence linking the events of excision and closing of linear Tc*1*s to heritable events, such as the mutations that result from reintegration of Tc*1* into germ-line chromosomes. Indeed, high-frequency excision has been shown to be limited to somatic tissue[6]. The role of either the linear or closed circular molecules in the transposition process in *C. elegans* and other organisms is unknown. Extrachromosomal copies of the *copia* family of transposable elements in *Drosophila melanogaster* have been described[8], but their role in transposition is unknown. *Copia* transposable elements have direct terminal repeats, in contrast to Tc*1* elements which have inverted repeats; thus, the conditions and mechanisms by which these two transposable elements circularize are presumably different. *Copia* elements can be mobilized by hybrid dysgenic crosses, but it is unknown whether the closed circular form is involved. Tc*1*, on the other hand, appears to be constitutively excising in the Bergerac strain. The generation of new mutations resulting from excision or integration of Tc*1* is being investigated in our laboratories.

We thank Dr D. L. Baillie for valuable discussion and financial support and N. Mawji and K. Beckenbach for technical assistance. This research was supported by grants from the NCI (Canada) to A.M.R. and D.L.B.; the MRC (Canada) to A.M.R.; NSERC to Dr. D. L. Baillie; and an NSERC scholarship to T.P.S.

Sex and drugs . . . and science

John Treherne

Strong Medicine. By Arthur Hailey.
Michael Joseph with Souvenir Press/Doubleday: 1984.
Pp.430. £9.95, $16.95.

From the writer who brought to millions the glitter of *Hotel*, the drama of *Airport*, the intrigue of *The Moneychangers*, this immensely powerful novel takes the reader deep into the heart of the pharmaceutical industry where millions of dollars and millions of lives hang on every decision ... and into the heart and mind of an unforgettable woman.

THE manifest enthusiasm of Mr Hailey's publishers for his latest production even extends to sending a review copy to *Nature*. Evidently they hope to reach the hearts and minds of the scientific community, as well as selling the film rights. Their optimism is not entirely misplaced. There is widespread public and professional concern about the activities of international pharmaceutical companies; readers of the 9 August issue of this journal will recall Carl Djerassi's angry review of Gary Gereffi's book on the drugs industry and the Third World, under the headline "Making drugs (and soaking the poor?)".

There might be doubts about the depth of Mr Hailey's fictional study, but there can be none about the swiftness with which he grapples with his subject. In the Prologue we are "up forward in first class" on a Boeing 747 amidst caviare and champagne — next year (i.e. 1985). Eight lines down the first page, Celia de Grey, the international drugs tycoon, reminds her handsome, supportive husband, Dr (of medicine) Andrew Jordan, that *certain deaths may be drug-related*. Two pages later we are back in New Jersey in 1957. The harassed young Dr J. (attending the critically ill wife of a factory hand in a thunderstorm), gets very cross with Celia, the beautiful saleswoman from Felding-Roth Pharmaceuticals, who obligingly returns to the hospital with an untested drug called Letromycin. She rivets the doctor with blazing eyes and persuades him to administer Letromycin — and saves his patient. After this Celia never looks back: she is gratefully embraced by and, within another page, married to Dr J. ("a quiet civil wedding with a few close friends and relatives"); she persuades Felding-Roth *not* to market Thalidomide, has a baby, flings her weight about at sales conferences, has another baby and by 1963 is on the fast track at Felding-Roth.

The break-neck passage of time is signalled by the regular insertion of tense paragraphs seemingly culled from *Keesing's Contemporary Archives*. In 1972 ("The rock-music cult called 'Woodstock Nation' flared briefly, then burned out") Celia is despatched to Britain to nose out any local pharmacological talent. Between shopping trips to Harrods, she finds her way along Tennis Court Road to "Cambridge University's Biochemistry Building", there to seek the brilliant young Martin Peat-Smith who is in close pursuit of a memory-enhancing brain peptide, which, he hopes, will "perhaps eliminate mental ageing altogether". Celia is appalled by the gloomy squalor of what seems to be embarrassingly like a contemporary Cambridge research laboratory, is hardly mollified to be told that Fred Sanger once worked upstairs, but is much taken by Peat-Smith who is swiftly translated to the luxurious Felding-Roth laboratory at Harlow. There he gets to work to isolate Peptide 7, sacks the tight-lipped sadistic animal technician Gertrude Tilwick, seduces her beautiful replacement, Yvonne, and, eventually, Celia herself. There are quite a lot of spicy bits: Peptide 7 is not only an elixir but, it turns out, a powerful aphrodisiac *and*, apparently, a slimming agent.

Not surprisingly, Peptide 7 is an instant success; long lines form at pharmacy counters and Felding-Roth is well on the way to an increase in revenue of six hundred million dollars. Peat-Smith is elected to the Royal Society and there are rumours of a knighthood and a Nobel Prize. Meanwhile, Felding-Roth achieve another coup with Hexin W (a drug of rather vague pharmacological properties), the brainchild of the unpleasant Dr Vincent Lord who was very put out by the success of Peptide 7.

Unfortunately, Hexin W is discovered to have nasty side-effects and poor Celia (now the boss of Felding-Roth) is soon in trouble with the Federal Drug Administration and the persistent and unscrupulous Senator Donahue, who is intent on her destruction. Nevertheless, she manages a brief trans-Atlantic dash, next year (i.e. 1985), to witness Peat-Smith's investiture at Buckingham Palace. Yvonne (Lady Peat-Smith), looking lovelier than ever thanks to Peptide 7, is naturally very disappointed at not meeting Princess Diana, but excited by the prospect of Sir Martin's New-Blood post at Cambridge.

And that is where we came in, 400 pages before, with poor Celia returning to America to face the music. Will the Felding-Roth code of practice stand up to scrutiny by a Senate investigative committee?

Arthur Hailey's latest offering will doubtless help to relieve the tedium of many an uncritical hour up forward with caviare and back in economy class with a hamburger. Despite the cardboard characters and a strong-bronzed-arms-and-yielding-breasts approach, *Strong Medicine* does make the attempt to write about important issues in a surprisingly fair and even-handed fashion; for most readers it will probably constitute their only extensive reading on this matter of vital public concern. So we should, indeed, be grateful to the creator of Celia de Grey, Gertrude Tilwick, Peptide 7 and the nubile Lady Peat-Smith. ☐

John Treherne is University Reader and Honorary Director of the Agriculture and Food Research Council's Unit in the Department of Zoology, University of Cambridge. He is author of several novels, the most recent of which, The Trap, *will be published early next year by Jonathan Cape.*

Making scents

C.T. David

Chemical Ecology of Insects.
Edited by W.J. Bell and R.T. Cardé.
Chapman & Hall/Methuen: 1984.
Pp. 524. £30.

THE subject of chemical ecology embraces everything of ecological significance that is mediated in any way by olfaction or taste. It thus encompasses a vast amount of information and a great range of different behaviours. A full account of the area would be expected to include material about pheromones, about chemical influences on interactions with other organisms — the finding of plant and animal hosts by smell, for example, and in prey detection and predator avoidance — and also about reactions to other chemicals in the environment.

It would seem that any book which attempted to cover the effects of all of these semiochemicals would be superficial; but *Chemical Ecology of Insects* proves that need not be the case. The editors have provided us with a selection of detailed and interesting chapters — starting with mechanisms of chemoreception; leading on through odour dispersal, insect orientation mechanisms to distant odour sources, plant-host finding, plant-herbivore relations, predators and parasites, chemical protection (including a long chapter on mimicry which seems more to do with "visual" than with chemical ecology), and spacing and aggregation; and ending with chapters on the pheromones of bark beetles and social insects. The only serious omission is of a discussion of the relations of insects to vertebrates.

Such a range of material cannot be dealt with in detail here. So I will concentrate, quite invidiously, on one of the many good chapters in the book, and on the only bad feature.

Almost every other book covering insect pheromones discusses the maximum distance of effective pheromone communication on the basis of estimates of the time-averaged pheromone concentration at different distances downwind from the emitter, using three assumptions — that insects have a constant threshold for response to pheromone; that the response time of the insects is long compared to the time of passage past them of the turbulently dispersed puffs of pheromone; and that the wind direction is constant. All of these assumptions are wrong. In their chapter on odour dispersal, Elkington and Cardé give an excellent appraisal of the problem. They discuss the limits of time-average models, put forward other models, and assemble much experimental evidence to produce better ways of estimating the area from which insects might be attracted to an odour source.

The bad feature is the index. There are 324 entries only, quite inadequate for a book of this length. Publishers should not need to be told that ancillary features such as this make all the difference between a book being read and it being left untouched in the library. ☐

Political resources

Stephen Cotgrove

Development and the Environmental Crisis: Red or Green Alternatives?
By Michael Redclift.
Methuen: 1984. Pp. 149. Hbk £9.50, pbk £4.25.

WHAT is the connection between feminism, ecology and Marxism? And how, in association, might they save the environment of the underdeveloped world? It is these questions that Michael Redclift sets out to examine.

Marxists, however, have little to say about man's relations with nature — in general they see environmental problems as the outcome of the predatory and exploitative character of capitalism, and nature as an inexhaustible resource. So one wonders why Redclift spends so much of his short book exposing the inadequacies of Marxism. And while it is true that radical thinking and the emergence of new political parties has brought together an uneasy coalition of feminists, ecologists, anarchists and liberals in a search of an alternative to market-dominated, ecologically damaging and consumer-orientated industrialization, this book lacks an analysis of the constituencies from which such movements are drawn and their potential as bases from which political challenges may grow. It is a pity that the political dimension of environmental protection is explored within a somewhat partisan selection of political ideas.

Nevertheless we do need reminding that the environmental crisis is a global one and cannot be divorced from the conceptualization and analysis of development and the problems of the South. In his discussion of technology and the control of resources (Chapter 6), Redclift argues strongly that technologies are not politically neutral, either in their origins or consequences. The "Green Revolution" did not simply increase crop yields. It also

> redistributed income and wealth, materially affected land tenure institutions, introduced new marketing arrangements . . . and disrupted the ecology of natural resources [p.107].

Wealthy farmers who have access to credit and are better able to buy fertilizers and machinery flourish, and the gap between large and small farmers widens. By contrast, research in farming systems is intended to benefit those who employ their own resources and to increase yields without the same social consequences. Again, water technology

> provides opportunities for entrepreneurship which have important distributive consequences . . . In much of South Asia the control over water exercised by bureaucracies has enabled them to wield considerable political power [p.31].

The central lesson of *Development and the Environmental Crisis* is that protection of the remaining forests, and improvement in crop yields and in irrigation, are not simply technical questions which can be solved by conservation strategies. Both development and environmental protection are inextricably tied up with vested interests and the political and institutional arrangements which they support. But this book is unfortunately short on strategies which offer hope, and its style and organization tend to obscure the importance of the message. ☐

Stephen Cotgrove is Professor of Sociology at the University of Bath.

Questions of the Quaternary

D. Q. Bowen

Late-Quaternary Environments of the United States. Vol. 1 The Late Pleistocene, edited by Stephen C. Porter. Vol. 2 **The Holocene,** edited by H.E. Wright Jr.
University of Minnesota Press/Longman: 1984. Vol. 1 pp. 407, $45, £45. Vol. 2 pp. 277, $45, £45.

THESE two volumes arise from a series of meetings between American and Russian scientists, at Moscow and Baku (1976), New York and Salt Lake City (1978), and Irkutsk and Yakutsk (1980), sponsored by a co-operative agreement in environmental protection. Volume 1 covers the period 25,000 to 10,000 years ago, Vol. 2 10,000 years ago to the present. Both are subdivided into sections with specialist chapters.

To a large extent environments in the United States were climatically controlled by the Laurentide ice-sheet, not least during its decay. H.E. Wright Jr shows how the persisting ice, until 6,500 years ago in Labrador, may have caused increased seasonality in climate beyond its borders. Herein may be the explanation for the disharmonious faunas and floras of the late-glacial and early Holocene. Such increased seasonality and a picture of the time-transgressive response of natural systems to the forcing effect of climatic change (whereby the United States was transformed from a full glacial into a full interglacial state), form the background to the complex set of questions examined in the books. Here readers will be grateful to the editors for their helpful introductions.

Resolution of the issues, however, relies on adequate evidence and good-quality dating control. Almost inevitably, in a terrain as large and diverse as the United States, both will be uneven. Thus there is a contrast between the middle west — with its impressive isopol maps showing the development of Holocene vegetation (described here by Webb *et al.*) — and the west where detailed work on well-dated sites (Baker) is still required. The deficiency is remedied in part by the successful studies on packrat (*Neotoma*) middens (Spaulding *et al.*), though this work too needs to be extended beyond the south-west.

In a similar vein, the advance of montane ice is less well documented than that of the continental ice-sheet: in general the onset and decline of montane glaciation runs ahead of the continental ice-sheet, no doubt because of the lagged response of the latter to climatic change.

Of further importance in establishing time-transgressive events for use in climatic modelling are data showing falling pluvial lake levels some 13,000 years ago in the southern Basin and Range, but not until the end of the Pleistocene farther north (Smith and Street-Perrot). It is difficult to disagree with R.G. Barry in his call for the collection of even more accurately dated data as a prelude to realistic modelling of the contemporary atmosphere.

All will welcome the first major synthetic treatise on the Holocene — from the latest assembly of palaeoecological data on vegetational history (discussed, for example, by Heusser), at first colonizing, later in dynamic equilibrium and subsequently coping with a cooling which culminated in renewed montane glaciation (Burke and Birkland); to models of alluvial history reconciling vegetation and climate (Knox); to the pragmatic and careful evaluation of Kutzbach on climatic change; and to a review of archaeology (Aikens).

These two volumes follow in the tradition of *The Quaternary of the United States* (Princeton University Press, 1965). But times have changed. The books focus on the past 25,000 years only, a necessity arising from the vast array of data available, but also because of the relatively good dating controls available for that period. The restriction is also in part a response to the high level of sophistication now demanded of Quaternary data. This places the earlier Wisconsinan (last glaciation) and Last Interglacial in a somewhat depressing light, to say nothing of the Quaternary *terra incognita* before that time. Perhaps it will be one of the many triumphs of the present volumes that, as well as catalysing further work on the late Quaternary, they may focus some attention on the seemingly intractable problems of that earlier time — without the solution of such problems, the absence of a full explanation of the dynamics of atmospheric–oceanic–continental interaction through time will continue to frustrate full understanding of even the late Quaternary and the projection of its climatic trends to the future. Happily these new volumes will provide a visionary nudge forward along these highways. ☐

Alternative forms in bioenergetics

Hans V. Westerhoff

Physics of Bioenergetic Processes.
By L.A. Blumenfeld.
Springer-Verlag: 1984. Pp.132. DM 70, $27.20.

RATHER than writing a much-needed handbook on our knowledge of physics as applied to bioenergetics, Professor Blumenfeld claims that enzymic catalysis cannot be satisfactorily accounted for by the current principles of physical chemistry. He rejects the relevance of one of those principles — the Eyring equation — for enzyme reactions, as it assumes equilibrium between the transition state complex and substrate-plus-enzyme. Experimental evidence is reviewed indicating that shortly after undergoing a chemical transition from E to E^-, the conformation of an enzyme may still correspond to the equilibrium conformation of state E. Because this conformation generally does not correspond to the most stable conformation for state E^-, the enzyme will relax to a new conformation, E^{-*}. The transition state, says Blumenfeld, thus cannot be described as having an enzyme in a conformation defined by its chemical state. As an alternative, he proposes to describe conformational relaxation in mechanical terms.

In the usual — and quite successful — approach, the two states E^{-*} and E are just included as separate states in the description. It is characteristic of the book as a whole that Blumenfeld does not explain why such a treatment would fail.

The author also calculates that, for a gas engine of molecular dimensions, the information-energy needed to move the piston at zero rate would exceed the amount of work done. Thus molecular machines could not operate reversibly. Here, the flaw in the argument lies in the strictly mechanical interpretation of reversibility; reversibility merely implies that the ensemble (time) average of the piston movement is zero. Individual pistons may fluctuate rapidly. A similar snag is evident in Blumenfeld's alternative theory for energy transduction, which at the level of a single particle in a quantum mechanical box uses Newton's action = –reaction law.

The review sections in the book provide new information only where they describe results previously published in Russian. That information is useful, but it is clear that the *internal* inconsistencies in the chemiosmotic coupling theory suggested by Blumenfeld exist only in his interpretations of that theory. With respect to external inconsistencies, it is not news that the chemiosmotic theory does not survive all experimental tests.

Although slow conformational changes may prove to have a role in bioenergy transduction, Blumenfeld's assertion that already established physical chemical theories could not account for them is unconvincing. His alternative theory is even less so.

Hans V. Westerhoff is a visiting scientist at the National Institutes of Health, Bethesda, Maryland.

Selected theory

Mark Ridley

Conceptual Issues in Evolutionary Biology: An Anthology.
Edited by Elliott Sober.
MIT Press: 1984. Pp.725. Hbk $40, £38; pbk $19.95, £18.95.

WHAT is our modern philosophy of evolution? To judge from the generous, and, I think, representative selection of previously published works in Elliott Sober's anthology, it is mainly concerned with the "designful" properties of organisms — their adaptations — and with Darwin's explanation of adaptation, natural selection.

The most damaging philosophical criticism of Darwin's theory is that it does not explain adaptation at all. Natural selection, in Spencer's form, "the survival of the fittest", has often been said to be a circular argument; but all the relevant authors in this anthology would disagree. The point is here most clearly made by Gould. "Fitness" has two meanings: the number of offspring on average left by a type, and how well designed, in the engineer's sense, the type is. The fitness of an eye can be considered optically as well as reproductively, and in Darwin's theory the latter is the cause (but not the criterion) of the former. If anything, I found five papers spread through 80 pages too large a dinner, but this is the one part of a subject, often criticized for its interminable and sterile controversies, on which all the professionals now agree. Let us indulge the celebration.

If natural selection does explain adaptation, we can proceed to three more questions. For the benefit of what kind of entities does natural selection produce adaptations? How well adapted are those entities? What kind of explanation is it? Now the disagreement begins. The first question is professionally phrased as "What is the unit of selection?". The main answers on offer are the gene, the organism and the group; and the main controversy concerns Williams and Dawkins's argument in favour of the gene. Fifteen pages of Dawkins (no Williams) stand against 95 from Gould, Lewontin, Sober and Wimsatt who variously argue for selection at "higher levels"; but unfortunately the main arguments for Williams and Dawkins's position are nowhere explained. The Dawkins paper (on the "extended phenotype") aims to extend, rather than defend, his case, and his critics, although they describe (sometimes even fairly) the theory they oppose, do not pause to expound it.

The argument, in condensed form, is this. The unit of selection will be, in a sense, the unit of heritability, because natural selection cannot act on non-heritable entities. Organisms are not inherited, because they die; "higher genetic levels" are not inherited, because they are broken and recombined: the unit of heritability will be something smaller, which Williams and Dawkins have chosen to call (and *define* as) the gene. If, in the kind of complex situations that Wimsatt, Sober and Lewontin discuss, that unit is longer than a cistron, then the gene (in Williams and Dawkins's sense) is longer than a cistron too.

In practice, however, Williams and Dawkins do not apply their argument to the problems of population genetics, but use it to think about what kind of adaptations will be favoured in particular environments. That application is strictly circumscribed. Williams and Dawkins have not been trying to explain everything in biology solely in terms of genes. Wimsatt, however, directs his criticism against a hopelessly ambitious theory of genic selection, which he has practically pumped up into *ex DNA omnia*:

> T2: (Dynamical thesis): Processes at the genetic level determine (and are the primary and ultimate) explanations for processes at all higher levels.

It is quite easy to make mincemeat of this, especially if "genetic level" is identified with a single genic locus. Wimsatt only needs to argue "that understanding evolutionary processes requires the invocation of causal mechanisms and nomic regularities" concerning things other than genes, for his work of destruction, against T2, to succeed. Against Williams and Dawkins, however, he is rather wide of the mark.

Actually, because genes are propagated in sets by the thousand through organismic agency, the selection of genes often produces organismic adaptations. There is broad agreement that organismal (rather than genic or group) adaptation is common, the disagreement being mainly about whether organismal adaptation is caused by the selection of genes or "higher levels". But either way we can ask how important the theory of natural selection is by asking how well adapted organisms are. If adaptation is uncommon, and imperfect, natural selection may remain its proper explanation, but will be unimportant. The five authors here (Lewontin, Gould, Oster, E.O. Wilson, Maynard Smith) all agree that organisms are only imperfectly adapted, because the range of genetic variation available for selection is limited. The argument is strong, and not (so far as I know) doubted by anyone; which is only unfortunate for Lewontin and Gould, who would discover an orthodoxy of "adaptationists" (all of whom believe organisms to be perfectly adapted), portray them in caricature, and analyse them with Marxist absurdities.

Sober remarks in his preface that it is difficult to distinguish the science from the philosophy in this anthology. For the most part I would agree; but only for the most part. In the sections that discuss whether theories are true, the science is indeed generally indistinguishable from the philosophy, and there are numerous scientific authors. The distinction could be made; but only superficially, by language and style (I could not help noticing the philosophers are more long-winded than scientists, but perhaps that is only the selection). Two sections, however, deal not with the validity, but with the nature, of theories — these are on functional explanation (teleology) and the reduction (or not) of Mendelian principles to molecular genetics — and they are entirely written by philosophers. Only, it would seem, when philosophical argument is used to criticize theories do scientists become seriously interested.

The final section takes leave from the theory of natural selection. Mayr, and Sokal and Crovello, discuss the nature of species — whether reproductively ("biologically") or phenetically defined — and Hennig, Hull, Felsenstein and Farris discuss the three main schools of classification.

I often wonder who buys these anthologies. They are usually too expensive for individuals; but why on earth should a library buy a selection of papers it already possesses? I think *Conceptual Issues in Evolutionary Biology* may be an exception. Most of its contents originally appeared in philosophical journals that are not subscribed to by biological libraries: but they should all interest biologists who enjoy thinking about the theory of evolution. And every biological library in the world, I hope, eagerly serves that species of reader.

Mark Ridley is Astor Junior Research Fellow of New College, University of Oxford, and author of The Explanation of Organic Diversity *(Oxford University Press, 1983).*

Keeping cool

H.M. Rosenberg

Matter at Low Temperatures.
By P.V.E. McClintock, D.J. Meredith and J.K. Wigmore.
Blackie: 1984. Pp.258. Hbk £19.75; pbk £10.25.

IT IS time that we had a new introduction to low temperature physics, and this book fits the bill very satisfactorily. Each of the three authors is well-schooled in the cryo-arts and together they have produced a unified text in decent English, with the occasional felicitous turn of phrase that made me pause and smile.

The book assumes a background of undergraduate physics, but the first three chapters gently remind the older reader of certain essentials. For the final-year undergraduate and the beginning graduate student (by whom the book will probably be most used) they will act as a useful revision.

The authors begin by introducing the general principles of low temperature physics, with particular emphasis on the third law of thermodynamics, the effects of zero point energy and macroscopic quantization. The next two chapters deal with lattice vibrations and electrons, respectively, and in each case the differences between the behaviour of crystalline and of amorphous materials is well brought out. The meat of the book comes next in accounts of superconductivity, liquid helium 4 and liquid helium 3 (including the properties of mixtures of ^{3}He and ^{4}He). In each case a simple phenomenological introduction is given as well as an outline of the current theory—with ample references for those who need a more detailed theoretical treatment. The final section of each of these chapters attempts to bring the reader up to date (to 1983) with developments in the most recent fields of interest—the properties of one-dimensional conductors and the search for other boson and fermion fluids.

The last two chapters cover more practical matters. Chapter 7 gives a good outline of experimental methods — ^{4}He and ^{3}He cryostat design, the dilution refrigerator, magnetic and Pomeranchuk cooling — and there is a helpful discussion on thermometry for various purposes. Finally, the authors turn to the applications of low temperature physics, the major emphasis, of course, being on superconductivity (high field electromagnets, the application of Josephson effects in computer elements, squids and other devices). This concluding chapter ends with a brief account of the uses of liquified gases themselves, including the interesting application of superfluid ^{4}He as a couplant in the acoustic microscope and as a non-reacting surface in the neutron bottle.

All in all, this is a good useful text. Not only that, it is enjoyable to read—an unusual and refreshing attribute. □

H.M. Rosenberg is Reader in Physics at the Clarendon Laboratory, University of Oxford, and a Fellow of St Catherine's College.

New in paperback: Jonathan Slack's *From Egg to Embryo* published by Cambridge University Press, price £9.95, $24.95. For review see *Nature* **306**, 294 (1983).

New for neuroscience

With the meeting of the American Society for Neurosciences this week, we feature a range of products to interest the neurosciences expert, including a new assay for monitoring tricyclic antidepressants.

● A new HPLC assay that monitors the five major tricyclic antidepressants and active metabolites simultaneously in serum or plasma has been introduced by Waters Associates. The Waters HPLC assay of the tricyclic antidepressants (TCAs) simultaneously monitors amitriptyline, imipramine, desipramine, nortriptyline, doxepin and their clinically relevant metabolites in the same assay without cross reactivity. The assay has been evaluated for interference, correlation with GC and linearity and takes just 12 minutes. Full documentation is provided in a method book. The TCA Assay was designed for Waters QA-1 Analyzer, an HPLC system providing convenient push-button operation. With the same instrument, technicians can perform assays of other psychotropic agents such as tetracyclics, butyrophenones, phenothiazines, benzodiazepines and other therapeutic drugs.
Circle No. 100 on Reader Service Card.

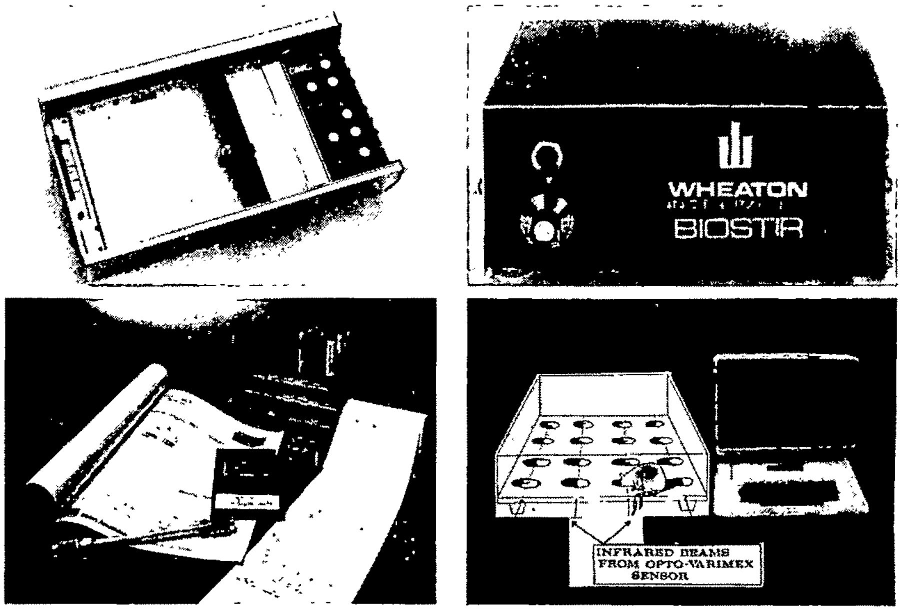
● The recent 'hole-poke' program developed for Columbus Instruments animal activity meters, monitors simultaneously eight animal cages equipped with "hole-poke" boards. Each time an animal pokes its nose into one of the 16 holes located in the cage's floor, it interrupts two crossing infrared beams. Information about interruption is decoded by the Apple III computer which keeps track of the number of pokes in each hole, the time an animal spent with its nose in the particular hole, as well as totalized number of pokes and time spent "poking" for each animal cage. The "hole-poking" method is an established procedure for testing an animal's exploratory behaviour, a valuable indication of animal brain functions. Information collected by an Apple II computer is periodically printed and stored on the disc. The same system can be used to monitor animal feeding activity with feeders (food dishes) located underneath a "holed" floor. When monitoring animals' feeding, computer results will correspond to numbers of visits to the feeders and time spent eating. Animal food preferences are easily established from computer records. "Hole-poke" systems can be applied in neurotoxicology, experimental psychology, development of new drugs, as well as studying nutrition. Other Apple II computer programs from Columbus Instruments allow plotting of animal's movements, number of rearings, animal rotational behaviour and separation of stereotypic from ambulatory activity.
Circle No. 101 on Reader Service Card.

● LDC/Milton Roy is pleased to announce a new interface package for the CI-10 computing integrator to an Apple II or Apple IIe computer. The new interface allows all CI-10 functions to be accessible from the Apple Keyboard. In addition, any CI-10 file (slice files, peak files or method files) can be loaded from the CI-10 to the Apple for further data manipulation or enhancement by the Apple. This additional capability of the LDC/Milton Roy CI-10 is designed for ease of use and provides the user with an independent chromatography integration channel for the Apple computer. Up to 15 CI-10 computing integrators can be networked from one IEEE board.
Circle No. 102 on Reader Service Card.

● Two new models in its 700 Series laboratory XY recorder are being introduced by Allen Datagraph, Inc. Model 720 offers eleven ranges in X and Y and accepts Option 30, which provides digital control of the recorder and annotation of plots. Model 725 has eleven ranges plus a built-in time base. These new models extend the usefulness of the basic XY recorder in OEM and laboratory applications. The 700 Series' standard features include Pad-load paper supply, DC servo operation, sealed feed back potentiometers and low drift circuitry. These recorders offer fibre-tip pens, optional carrying case, English or metric calibration and a digital interface option.
Circle No. 103 on Reader Service Card.

● Wheaton Instruments announces the new Wheaton Biostir low profile heavy duty magnetic stirrer designed for use with Wheaton Celstir suspension culture flasks; it will accept one vessel up to 8 litres in size. The solid state speed control provides a speed range of 25 to 350 r.p.m. even with wide fluctuation in line voltage. The unit features a powerful alnico magnet for increased efficiency and the low profile cabinet conserves incubator space. For added protection, the circuit board has been coated with a special sealant so that the Biostir low profile stirrer can be used in high humidity incubators.
Circle No. 104 on Reader Service Card.

● Scientific Systems, Inc., now offers a pneumatically-actuated version of its 3XL Injection Valve, designed to permit automated and manual use of the valve. Available for both internal and external loop operation, the pneumatically-actuated 3XL provides load-to-inject times of 1/10 second at 50 psi. On the internal loop version, switching from one sample loop to another takes only 15 seconds. The valve has several unique design features that maximize efficiency. A straight flow path from the sample loop to the column prevents sample flow disruption and maintains a more symmetrical and efficient peak shape. To minimize band dispersion, the 3XL allows direct coupling of standard size columns to the valve. An event marker aids data handling.
Circle No. 105 on Reader Service Card.



Allen Datagraph Model 720 recorder (top left), Wheaton Instruments' Magnetic Stirrer (top right), Waters' HPLC assay for monitoring antidepressants (bottom right) and 'hole-poke' program for monitoring animal behaviour from Columbus Instruments (bottom right).

● Dekasol from ICN Biomedicals Inc. is a powerful concentrated solution formulated for the rapid control of radioactive contamination. Dekasol removes radioactive particles from surfaces by a two-way action. It will sequester metallic ions which contaminate surfaces, and, because of its high detergent action, will lift and suspend contamination particles. The contamination is then easily rinsed away with water. For routine use, Dekasol is diluted 20 to 50 fold and can be used on virtually any type of surface; it is mild enough to be used on skin.
Circle No. 106 on Reader Service Card.

1-1-57
A. Bates

● A new patch clamp stimulator is now available from the Medical Systems Corporation. This unit, model S-100, is a low-noise pulse generator which is specifically designed for use with extra cellular patch clamps. When functioning as a stimulator, the S-100 provides voltage pulses (jumps) to the patch membrane. These same pulses can also be used as test pulses to measure the resistance of the patch pipette. The S-100 can be operated in a "free running" mode, in which it provides repetitive pulses to the patch; or in a "single shot" mode, in which it is triggered manually or externally. The output pulses of the S-100 are always paired and the first and the second pulse have independently adjustable magnitude and duration. Both unipolar and bipolar output pulses are available. The Model S-100 also functions as a simulator of single channel activity with a pseudo-random channel generator included for control and simulation of patch activity. Medical Systems Corporation is a specialist in the development and marketing of instruments used in electrophysiology.

AUTHORS WANTED BY N.Y. PUBLISHER

A well-known New York subsidy book publisher is searching for manuscripts worthy of publication. Fiction, non-fiction, poetry, juveniles, travel, scientific, specialized and even controversial subjects will be considered. If you have a book-length manuscript ready for publication (or are still working on it), and would like more information and a free booklet, please write:

Vantage Press, Dept. D-69
516 W. 34th St., New York, N.Y. 10001

Circle No. 28 on Reader Service Card.

World Precision Instruments' Series 10000 micromanipulator (left) and Dekasol solution for the control of radioactive contamination from ICN.

● From World Precision Instruments Inc. the Model DVC1000 Dual Voltage clamp provides continuous measurement of the transepithelial currents while voltage clamping two separate membranes (one membrane as a control and the second membrane as the test material) at zero volts or at a preset voltage difference. This procedure allows the study of membrane permeability and ion transport under different experimental conditions.
Circle No. 108 on Reader Service Card.

● Hydraulic coupling of the fine control on World Precision Instrument Inc.'s new Series 10000 micromanipulators virtually eliminates vibration associated with touching the micromanipulator during adjustment. Hydraulic movements feature backlash-free operation and typically exhibit drift of less than 1 micron in a twenty-four hour period. Model 10000 can be fitted with one, two, or three hydraulic movements and offers 0.2 micron resolution for fine control. Coarse adjustment is manually controlled and has a resolution of 0.1 mm. Model 10,000 micromanipulators with hydraulic drives are available in right and left-handed versions and are supplied ready to use.
Circle No. 109 on Reader Service Card.

● The new Series 200 X-Y Recorder, featuring Houston Instrument's patented capacitance rebalance position transducer, operates without the friction and electrical noise associated with slide-wire potentiometers. The Series 200 performs with high speed and accuracy and can meet the needs of both educational and industrial users, with applications ranging from materials testing to compound analysis. By flipping a switch, users may select one of eleven input ranges on pen (Y) and beam (X) axis, starting at 1mV/inch, or one of eight beam (X axis) speed levels, ranging from 200 seconds/inch to 1 second/inch. A slew rate of more than 30 inches/second ensures high fidelity recording of test and measurement data.
Circle No. 110 on Reader Service Card.

● The Multipoint Recorder/Logger (MRL) from the Esterline Angus Instrument Corporation provides analog trend recording, digital (alphanumeric) data logging or a combination of both and a comprehensive choice of user-programmable performance functions offered in a multipoint recorder/logger. Simplified, programming is accomplished through a colour-coded panel keyboard. Programmable features include: mode of operation, chart speed, scan interval, peak or valley detection, printout/output time, scale limits, engineering units, real time clock and calendar, and three alarm setpoints per channel in standard or failsafe mode.
Circle No. 111 on Reader Service Card.

● A new microprocessor controlled osmometer, the Multi-Osmette from Precision Systems, performs freezing point determinations of osmolality on up to 24 samples. The new instrument accepts micro samples in disposable plastic tubes, calibrates automatically, makes the determination of osmolality, and with an optional printer, provides a fully annotated record for each sample. The complete cycle is activated by a single button. Automatic processing of multiple samples can free as much as an hour of technician's time, and a printed record eliminates questions of identification of results; use of inexpensive disposable plastic sample tubes eliminates the problems of glassware washing and breakage. When stat determinations are required, the automatic cycle can be interrupted. One or more stat samples can be introduced and run, after which the autocycle is resumed. Operation of the automatic sampler changer is simple, with easy operation for single samples when desired.
Circle No. 112 on Reader Service Card.

A council ripe for abolition

The British research council with responsibility for the natural environment could with profit be dismembered into smaller pieces.

THOSE who read the account of the collapse of the British Geological Survey's reason for existence on p.499 should prudently also refer to last week's complaint of maladministration at the Science and Engineering Research Council (*Nature* 4 October, p.397) and to the opinion expressed two months ago (*Nature* 26 July, p.261) that the British research enterprise is either bankrupt or about to become so. The circumstance in which an organization employing 1,000 professional geologists should be compelled, at least during the present financial year, to reduce to one-third its geological surveying is a scandal by any standards. If resources had been wasted on such a scale by a joint-stock company, and if they had been measurable in money terms, the people responsible would have been sacked. Because, in this case, the waste can be assessed only intangibly, by the frustration and disappointment of those concerned, by the lack of what they might have done and by the contagious effects of their sunken morale on other professional people, there is every likelihood that under the British system, the villains responsible will still be mentioned in future lists of public honours.

The origins of the scandal are clear. The Geological Survey of Britain began work in 1835, a short while after the Reform Bill of 1832 and a full three decades before *Nature* began appearing every week. For most of its history, the survey was administratively untouched, but in the early 1960s, what with the rhetoric of Mr Aneurin Bevan (since dead) on the need for a thorough exploration of what lies beneath Britain, and the fashionable preoccupation with tidiness, it was inevitable that a government committee (under the late Sir Graham Sutton) should advocate setting up a research council concerned with the natural environment. The original idea was that the council should bring together the old geological survey, the Meteorological Office and various bits and pieces so as to forge an entirely novel instrument for multi-interdisciplinary investigation of the natural world, straddling ecology, the oceans and the atmosphere (not to mention the pollution thereof) as well as the solid Earth.

The Natural Environment Research Council (NERC) was already in a sense a failure when it came into being in 1967. The Meteorological Office had used its influence with the defence departments to opt out, with the result that the geological survey was the largest operational function with which NERC was involved. For many years, the new council did its best to combat the then expansionist tendencies of the geological survey (renamed for a time the Institute of Geological Sciences). Since the British Government's enthusiastic but uncomprehending adoption of the Rothschild recipe for the organization of civil science in 1973, the council has steadily won that battle.

Starting with the Rothschild precedent that government departments should pay for research they find worthwhile, NERC has sent the British Geological Survey (BGS) out into the market place, bidding for whatever odd jobs oil companies and minerals companies have wanted done. Nobody has ever examined the propriety of the accounting principles on which BGS has been able to win this business while still enjoying overhead support from NERC. The conflicts of interest that must arise when an agency whose prime function is to compile a public data bank (a geological survey) is also compelled to do jobs for private companies in return for cash have not been considered seriously. And NERC seems never to have asked the broader question whether a country such as Britain needs a geological survey (the answer must be yes) and, if so, how it should be managed.

For those concerned, there are inevitably extenuating circumstances. NERC, from the outset fearful that one of its operational tails (the geological survey) would wag the dog (itself), and distract it from the general support of the Earth sciences, has consistently and properly been seeking to quarry more funds from its budget for the support of academic science. The survey, on the other hand, has fought hard and often arrogantly in defence of its unspecific goal of mapping the subsurface of the United Kingdom in a manner and to a timetable of which it is the principal arbiter. The trouble, for NERC, is that much else of its business is organized into independently operational units, but without clear objectives of what the operations are intended to achieve by when. There is, for example, a British Antarctic Survey (with a post-Falklands doubled budget), an Institute of Oceanography lacking formal connections with academic oceanographic research and an Institute of Terrestrial Ecology whose work (mostly good) is more easily described than its function understood. NERC has been beastly about the annual budget to all these organizations, no doubt winning other false economies like those effected at BGS. But NERC's failure to bring about a radically different pattern after nearly twenty years, exacerbated by the government's failure to recruit a full-term successor to Sir Hermann Bondi as NERC's chairman, points to a simpler solution.

Why not simply disband the Natural Environment Research Council, finding more suitable homes for the laboratories in its charge? That task should not be nearly as formidable as it seems. The geological survey is necessary and could be continued securely if it were the principal responsibility of a ministry, probably the Department of the Environment. The Institute of Oceanography should be integrated with academic research, while the ecology institute (three laboratories) should become the research arm of the Nature Conservancy Council (which, once, some parts of it were). It is not altogether a joke to argue that the British Antarctic Survey might go to the Foreign and Commonwealth Office.

Reorganizations such as these are no doubt more easily carried out with scissors and paste than on the ground but, for NERC and its masters, there seems no alternative to making the attempt. There is, however, a serious difficulty — what should be done with NERC's small but slowly-growing support for academic science? The obvious solution is to transfer this important rump to the Science and Engineering Council (SERC). The obvious snag is that SERC is not immune from precisely the kinds of troubles that afflict NERC, and is in any case already so huge that it dominates the whole British system for the support of civil science. Transferring responsibilities elsewhere (biology to the Medical Research Council, engineering to a new council as British engineers are forever asking) would not suffice. Transferring SERC's central facilities intended for university use to some trust that would use them on a European footing would be the ideal, but would not easily be traded off against the right of access to comparable facilities elsewhere. But while both NERC and SERC are in need of radical change (dismemberment and reform for the sake of flexibility respectively) the present is as good an opportunity as any to attempt this task.

Australia's problem

Mr Bob Hawke's government must be positive about its support for research.

AUSTRALIA'S Labor Government has chosen the oddest way in which to prepare for the impending election, most probably in December. During two years of office, Mr Bob Hawke and his colleagues have been more or less committed to the view that Australia needs to make a special effort in industrial innovation if it is to be successfully dragged into the modern world. The prophet of change has been Mr Barry Jones, minister of science and technology in Mr Hawke's government, whose book *Sleepers, Wake!* has indeed stirred many Australians from their contentment. So why is it that in Mr Hawke's pre-election budget, published just over a month ago (see *Nature* 4 October, p.405) Mr Jones's department has fared worse than any other? The cash increase does not match inflation, so that the resources available will actually be reduced. So what will happen now, both to Mr Jones and to his policy?

Australia, with a population half that of California, is economically the victim of its rich natural resources. For decades, Australians have been arguing the toss about the efforts they should make to add value to the primary products, in agriculture and minerals, which as exports have bought modest prosperity for what used to be the most successful practitioners of Western ways in the South and West Pacific. The standard political response has been to restrict overseas investment in Australian primary production, and to protect Australian manufacturing industry (which has never seriously caught on) from outside competition. Mr Jones's tract was meant as a plea for more adventurous initiatives. Why not recognize that the world is changing, and becoming more dependent on the self-conscious application of technology? Why not put the country's sophisticated technical community to better use, both by means of links with novel industries but even in traditional fields such as agriculture (as by the self-conscious encouragement of biotechnology)? And why not (because there is no choice) confess that Australia must make its way in the world in partnership and competition with the other economies of the Pacific basin, which include Japan as well as California?

While some of Mr Jones's tub-thumping has occasionally been naive, it is a shame that he has not been listened to more attentively, both by his colleagues in the government and by the technical community. The trouble with Australia, whatever the political labels its governments may be wearing, is that it is deeply conservative. (Changing governments is permissible, but changing the ways in which people earn their livings is something else.) This cast of mind is reflected in the pattern of Australia's research effort, which is substantial (for a primary producer). The Commonwealth Scientific and Industrial Research Organization (CSIRO) is eminently suited to the improvement of traditional agriculture and the more effective exploration for minerals (with substantial side-interests in such fields as solar energy), but is so heavily institutionalized that it cannot be the radical force that radical Mr Jones has been looking for. During his spell in office, Mr Jones has done his best to loosen the bonds of Australian self-satisfaction, and there have been some signs of success. But these do not amount to the radical change for which Mr Jones has been working.

What will happen next is anybody's guess. Mr Hawke may not be re-elected, in which case Mr Jones's ambition will for a time be forgotten, but that is not what the pollsters say. In the hope of salvaging something from the disappointments on the technical front during the past two years, it is reported that Mr Hawke is planning a great administrative initiative — some kind of super-ministry that will unite the Australian Government's responsibilities for research and for the support of industry. That will be a strictly cosmetic device, and one that must be meaningless on the eve of an election. It would be more profitable for Australia and for the present government, even at this late hour, if Mr Hawke and Mr Jones could work out a less negative plan than that implicit in the budget, whose objective seems to be to teach the technical community a lesson the hard way — cutting back on resources through existing channels with the unrealistic objective of forcing people into partnership with an industrial sector notoriously unwilling to spend resources on research. The government is right not to try to back winners in a horse-race not yet devised, but wrong to think it can conjure industrial support of research simply by cutting back on what it spends itself. Far better, in reality, to embark on selective support for imaginative work at the universities and CSIRO institutes, so providing a showcase of what may already be available. A sum of money not much greater than the \$A30 million set aside for the defence of the America's Cup would go a long way to help. □

Conservation cheers

The tide is running in favour of British conservation.

THE British conservation movement, a little to everybody's surprise (its own included) is in good spirits. So much is clear from the tone of the tenth annual report of the Nature Conservancy Council (published on Tuesday), which gives an account of a frustrating year without undue wringing of the hands. Evidently the council's confidence has been reinforced by what others active in the field have been saying. The House of Lords committee which a few months ago pointed to the conflict of interest between agriculture and conservation, and asked that it should be redressed, has been good for people's morale. The Countryside Commission, like the Nature Conservancy Council a statutory body with formal functions defined by the Countryside Act (1981), has also been strong and sensible about the importance of the appearance of landscapes of all kinds. Already the council appears to have forgotten last year's rows, when the then chairman found that the government's refusal to renew his appointment did not excuse him from his duty to support an agriculture minister in a confrontation with farmers angry that ploughing a marsh in Somerset might be forbidden.

The most astounding development, however, is the noises being made by the National Farmers' Union, hitherto hot-gospellers of hedgerow destruction (with financial help from the British Government), contour violation by access roads (again grant-aided in the hill regions that are most easily damaged) and the replacement of traditional buildings by metallic barns designed to be seen from as far away as possible. The union's officials are now talking about the need to abate the rush for farm production by some consideration for conservation. Even if, as may be possible, the farmers have not repented of their ways but have merely calculated that it will be the worse for them if they alienate all countrygoers, the development has been a heartening surprise. The danger now is that people will be lulled into complacency.

One obvious trap stands out from the Nature Conservancy Council's report, which repeats the now familiar tale of its difficulties in administering the section of the Countryside Act allowing the designation of "Sites of Special Scientific Interest". When properly designated, sites cannot be altered radically by their owners (who may nevertheless have to be compensated for income forgone, or even bought out). The practical difficulty is that the council, with its small staff, cannot cover the ground as quickly as it wishes or as prudence requires. In the three years since the act became law, a third of 4,000 sites have been dealt with, but those remaining include some of the hardest cases. The council is now complaining of loopholes in the law, but it should seriously consider whether it should not restrain its ambitions for notifying so many sites. It has other powers (to protect species or create nature reserves) which might often serve the same purpose. If the tide of opinion is flowing in the right direction, there is less need to hurry. And it is asking for trouble to urge, as in this week's report, that there should be nationally agreed percentages of consumption of temperate foodstuffs to serve as permanent targets for the farming community. □

Genetic manipulation

Rifkin strikes against gene transfer experiments

Washington

ANTI-genetic engineering activist Jeremy Rifkin once again thrust recombinant DNA research in the United States under the spotlight of national attention last week. Rifkin's lobbying organization, the Foundation on Economic Trends, together with the Humane Society of the United States, has filed a suit in the district court here to halt gene-transfer experiments being carried out in livestock by the US Department of Agriculture (USDA). The plaintiffs allege that the experiments are a violation of the ethical canons of civilization and represent a new form of cruelty to animals.

Don't say Rifkin AND Hollywood didn't warn you....

The experiments entail injecting fusion genes that include the DNA structural sequence of the human growth hormone into the fertilized eggs of sheep and pigs. When similar experiments are done with mice, some of the resulting animals express the human gene, and so grow larger and faster than normal mice (see *Science* **222**, 809; 1983). The new work is a collaborative effort between Dr Ralph Brinster of the University of Pennsylvania Veterinary School and a group under Dr Vernon Pursel at USDA's agricultural research centre at Beltsville, Maryland.

While the human origin of the growth hormone sequence doubtless added to the public's fascination, Rifkin makes clear that his objects apply to transferring any foreign genetic material into the germ line of a species. It would be morally objectionable to transfer animal genes to humans, Rifkin says, and it is similarly objectionable to transfer human genes to animals. Furthermore, the biological stability of the species would be threatened if farmers switched in large numbers to "super animals" containing genes from other species. Rifkin believes there would be undesirable economic and evironmental consequences of the general use of genetically engineered livestock, with small farmers being forced out of the market and higher prices being passed on to the consumer. The Humane Society of the United States argues that physiological imbalances in genetically engineered animals would cause suffering.

Brinster, evidently feeling besieged, was trying to avoid the press last week, but wants the public to understand the possible benefits from the research. Apart from the prospect of better and cheaper meat and other animal products, gene transfer experiments hold great potential for cancer research, especially with Leder's recent demonstration that transgenic animals can inherit a propensity for particular cancers.

The human growth hormone sequence was used simply because it is well studied and is easier to detect in mice than the rat sequence originally used (see *Nature* **300**, 611; 1982). Despite the difficulties of working with opaque eggs, the livestock system is working well. Brinster declines, however, to discuss preliminary findings until definitive results are ready for publication. So far "several hundred" eggs have been injected with the growth hormone fusion gene; if successful, the experiments will allow further work on the processing of gene products, because livestock animals provide larger tissue samples than mice.

USDA officials concede that Rifkin's challenge will probably be pursued by the court, but they have not yet studied the litigation in detail. Whichever side loses in the first round of the action is certain to appeal, and the case could drag on for a long time.

The three causes of action cited by the plantiffs refer to the creation of federal common law nuisance and violations of the National Environmental Policy Act and the Administrative Procedure Act. In essence, the claim is that USDA's animal breeding programme is at odds with policies approved by Congress in other areas, and that USDA has not adequately considered other strategies or the impacts of its programmes. Rifkin is also trying to introduce an amendment to the guidelines used by the Recombinant DNA Advisory Committee of the National Institutes of Health, which would restrict research in the area and which due to be discussed later this month. In the meantime, the research continues. **Tim Beardsley**

Dutch universities

Small print conceals more cuts

THE Dutch universities will feel the pinch again next year, despite ministry of education figures that make it appear that university research spending has increased substantially. The ministry has achieved this sleight of hand by recalculating the time a university teacher spends on research.

In the 1970s, the ministry assumed that natural scientists in the Netherlands spent 36 per cent of their time on research — and their salaries were debited from the research budget in proportion. In 1985, however, the assumption will be very different; research time is estimated to be 44 per cent of duties on average, varying from 18 per cent in academic hospitals to 61 per cent in mathematics.

The result in the nominal university science budget is that what appears to be an increase, from Dfl 1,452 million (£341 million) in 1984 to Dfl 1,796 million (£418 million) in 1985, is actually a decrease in real terms. If the budget is calculated using the 36 per cent research time figure, and compared at constant prices with the 1980 figures, it appears that the 1983 budget was just 93 per cent of the 1980 figure, the 1984 budget 92 per cent and next year down to 91 per cent. Of course the new calculations (which put the 1985 university research figure at 114 per cent of that in 1980, at constant prices) do not make more money available to research, and by raising the apparent budget make it more vulnerable to the threat of cuts at cabinet level. However, the re-calculation was merely for administrative convenience, and not a policy matter, a government spokesman said last week. The new research-time figures are based on careful surveys of what Dutch researchers actually do, and are not pulled out of a hat. Interestingly, though, they conflict with lower fractions generally assumed in other countries. In Britain, for instance, the University Grants Committee estimates research time to be just over 30 per cent of duties. **Robert Walgate**

- Total Dutch spending on research and development will increase slightly next year to Dfl 8,132 million (£1,890 million), according to recent government predictions. Government spending will be Dfl 3,882 million (£903 million), a slightly lower fraction of the Gross National Product (GNP) (0.97 per cent) than last year (0.98 per cent), but still larger than in the years 1980-83 (0.90-0.93 per cent). Industry will spend Dfl 3,800 million (£884 million), the government estimates, and another Dfl 450 million (£105 million) will go to international projects.

Dutch research spending is therefore below the European Economic Community average as a fraction of GNP, but only 3 per cent of the Dutch research and development budget is spent on defence. This compares with 33 per cent in France. **Casper Schuuring**

French medical institutes

Twelve-year rule begins to bite

THE French medical research council, INSERM, is approaching its twentieth anniversary — and a time of testing. A government attempt to stop ageing laboratory directors sleeping at their posts, known as the "12-year rule", takes effect next year — when all who have been directors for 12 years or more must resign. Thus 60 out of 250 INSERM directors must go or reapply, which may explain why protests over the "bureaucratic" rule have been more bitter at INSERM than at any other French research council affected.

At the Centre National de la Recherche Scientifique (CNRS), for example, there has been little resistance — perhaps because, despite its size and age, CNRS has only 50 directors affected by the rule. This is attributable to physicists who often change directorships voluntarily before the 12 years are up, and to biologists who have been applying a policy of group concentration and reorganization, thus anticipating directorship problems. Altogether, CNRS seems naturally to have shown more of the flexibility that the 12-year rule is intended to encourage.

Flexibility will come, even at INSERM. Director-general Philippe Lazar is privately delighted that the "majority" of the 60 affected directors have not yet reapplied (with revitalized research programmes), as they are entitled to do by mid-November. This should give him some fun next year, when he will be able to reallocate this research potential according to new priorities now being defined by his advisory science council.

At INSERM, there were two kinds of resistance to the rule: from conservatives, whom — broadly speaking — the rule was designed to shift; and from a group of first-rate directors who are likely to remain directors after reapplication, but who deplore the paperwork and time involved. But among the latter, many have found the exercise of redefining 12-year research programmes "refreshing", Lazar claims.

Lazar, a medical statistician, has set out to refresh INSERM since he took over in 1982. "The image of the ivory tower has gone", he says. The 12-year rule is important to him because it makes it possible for directorships to change hands without the slur of explicit negative judgement on the incumbents.

Another major change at INSERM during Lazar's term has been a shift towards health service research, one outcome of an "honest review of strengths and weaknesses" instituted by Lazar and completed this summer. Some of the changes expected by next spring include:

- The creation of a new scientific committee (there are at present eight) in "the human and social sciences applied to health" with the objective of establishing new research fields and units.
- A general reorientation of priorities for new units established by INSERM, and a similar reorientation of INSERM external grants.
- An improved recruitment system for new scientists — with 60 new posts next year.

Several problems remain unsolved, however. There should be more foreign experts in review committees, Lazar admits, but "we shouldn't expect that foreign experts will do miracles". In INSERM itself, there are "silent experts" who refuse to judge their colleagues, but that is changing. And while INSERM (like the whole of France) is hamstrung by the total lack of postdoctoral fellowships, plans are under way at the research ministry to introduce a fellowship system.

Otherwise, the resolution of one old problem may mean less cash for French biologists. In its early days, INSERM competed openly with CNRS for the best biologists, to the benefit of many. But under a new agreement between the councils, that boon will end. Laboratories which have been jointly funded for no good policy reason will now have to adhere either to CNRS or INSERM, probably with a consequent loss of funds after a four-year transition period.

But to replace the past *ad hoc* joint support, there will now be three clear structures for collaboration: a few (10–20) existing common laboratories where the basic research goals of CNRS clearly overlap with the medical goals of INSERM; new "concerted development units" where INSERM and CNRS wish actively to set up joint action and "allied units" where, for example, CNRS staff may be working in an INSERM laboratory, or vice versa.

Thus clarity is entering the INSERM–CNRS relationship for the first time in twenty years, and French biomedical belts may tighten as a result. **Robert Walgate**

Soviet geology

Deep boreholes yield data-harvest

ON 7 September 1984, drilling operations began on a projected 15-km borehole through the Ukrainian crystalline shield from a site at Novoivanovka, near Krivoi Rog. This drilling project, involving more than 150 research institutes and "production collectives", marks a new stage in the Soviet deep borehole programme — the sinking of deep shafts specifically related to the search for metals.

Soviet interest in deep boreholes dates back to the beginning of the 1960s when the United States was planning to drill a "mohole" into the oceanic crust down to the Mohorovicic discontinuity between crust and mantle. Soviet plans have concentrated on drilling of several deep boreholes (12,000–15,000 km) at carefully chosen sites — the Kola peninsula, the Kura depression in Azerbaijan, the Urals, the Caspian depression and one of the Kuriles. At the outset, however, Soviet drilling technology was insufficiently advanced to reach the proposed depths. Oil drillings averaged less than 2,000 metres in depth, and the few shafts that passed the 4,000-metre mark were considered exceptional.

Not until May 1970 could work be started on the first deep hole, at a site 8 km north of Zapolyarnyi on the Kola peninsula, while the second, at Saatly in Azerbaijan, was started only in June 1977. Special drilling rigs developed by the Uralmash plant differ from US deep-drilling equipment in that the string remains virtually stationary while the bit, a miniature turbodrill, rotates. The special-purpose instruments, capable of withstanding high pressures and temperatures, include a miniaturized motor, developed by students at the Kaunas Polytechnic Institute, which can drill and analyse rock samples at depths of over 11,000 metres.

Already the programme has yielded interesting results. Samples from the Kola borehole have revealed in the Baltic shield aqueous solutions of carbon dioxide and helium at depths of 6,000 metres, the expected granite-basalt boundary at approximately 7,000 metres was found not to exist and the angle of inclination of beds which form outcrops of 45° was found to remain the same at increasing depths, contrary to the expectation that the inclination would increase. Fossilized microorganisms were found in strata believed to be 2,000 million years old. Fossils from the Saatly hole (shells and small corals) have confirmed that there had once been a shallow sea in that area.

In the Kola borehole the temperature at the 12,000-metre mark (on 28 December, 1983) was above 200°C, instead of the expected 100 to 120°. In the Saatly hole, the temperature at 7,500-metres was 140°C, less than expected, suggesting that there is no deep magmatic activity in the Kola depression.

The practical implications of the data have proved more valuable than expected. In the Kola borehole, traces of copper, lead, zinc, cobalt and nickel have been found far deeper than predicted, so the programme has been extended to include a further 20 holes in ore and hydrocarbon bearing localities. Boreholes in oil/gas-bearing regions will include sites in the Tyumen region, the Kuban, the north Caucausus, the Caspian depression and the Timan-Pechora region. The four metal-ore sites will be in the Urals, near Noril'ski in Uzbekistan and at Novoivanovka.

Vera Rich

Polish universities

Autonomy beyond reach

POLISH universities opened last week in somewhat gloomy circumstances. The Party daily, *Trybuna Ludu*, greeted the new term by observing that "for several years, the intellectual activity of the academic milieu has been declining" and has failed to produce "fresh achievements significant in world standards".

At the same time, the paper gave a strong hint that the autonomy of the universities was, essentially, part of an implicit bargain by which the university authorities, in their turn, assumed "co-responsibility" to prevent university self-governance being used as a cloak for "harmful" actions.

Neither of these criticisms is unexpected. The declining standards of Polish science have been repeatedly discussed, explained and excused in the Polish press during the past year, and may fairly be summed up as the result of the hierarchical planning of research during the Gierek regime (when every research project had, officially, to relate to a carefully graded ladder of "problems" of the national economy). But, now, all foreign currency for the purchase of equipment and journals has suddenly been cut off. The situation is so bad, a working party of the Polish Academy of Sciences warned last month, that without an immediate injection of hard currency, Polish science could come to a complete halt.

University autonomy has also been a contentious issue during the past year. The chief clash was over the election of university rectors, when three rectors-elect were vetoed by the Minister for Science, Higher Education and Technology, Dr Benon Miskiewicz; when the Warsaw University electoral college refused to accept his decision, its functions were suspended for six months and the minister let it be understood that he would appoint a rector of his own choosing. Yet when the university opened last week, the outgoing rector, Dr Kazimiedrz Dobrowolski, presided over the beginning-of-term ceremonies and, in his inaugural address, expressed the hope that the university would soon have a new rector, chosen by the electoral college.

It is now thought that Dr Dobrowolski came to an agreement with the minister during the vacation, by which he would continue in office until 15 February 1985, and that the electoral college would elect his successor when its term of suspension expires in February. But none of this has appeared in the Polish press, and there is no certainty that, even if there is another election, the minister will not again intervene if the choice is too "daring".

The issues of autonomy and of research standards are, in fact, related, since one of the major demands for academic autonomy formulated in the Solidarity period was the right of universities to determine their own research programmes, independently of state priorities. But even the autonomy granted by the 1982 Higher Education Act (considerably less far-reaching than was originally hoped for) is not always easy to implement. In a recent interview in *Polibyka* the rector of the Jagiellonian University of Krakow, Dr Józef Gierowski, noted that university self-government cannot be invoked to deal with the bottom-heavy structure of academic teaching staff, where too few assistants and junior lecturers are prepared to qualify themselves for professional posts.

The university, he explained, "being as it were a continuation of the function of the welfare state", is obliged to employ "scientific workers", for whom the PhD degree represents the "peak of their capacity or ambition". (Senior academic staff in Poland must hold the higher degree of *doctor habilitatus*). The only success for "autonomy" in dealing with such people is the acceptance of the principle that they must resign if they do not get their doctorate within eight years.

Polityka, which, although less liberal than before Martial Law, still enjoys considerable prestige, has during the past year given considerable space to problems of science and education. Recently it has been particularly concerned with the training of Poland's future scientific workforce, covering such issues as the falling interest among university entrants in the technical engineering sciences, the challenge of the "third wave", the relevance of "new maths" in primary schools, and the practice, recently introduced in some schools, of a longer school-day with Saturdays free.

US-Japanese education

One man's meat, another's poison

Tokyo

JAPAN and the United States have agreed to set up a joint 30-member council to compare their educational systems from May of next year. The move comes not before time, for both nations have been worrying about the weaknesses of their respective systems (helped along by reports of emerging IQ differences) and envying the strengths — real and imagined — of the other's.

At the Washington meeting between Japan's Education Secretary Yoshiro Mori and US Secretary of Education Terrel H. Bell that gave approval to the council, Bell, reflecting growing US desires for a return to a more disciplined educational system, lavished praise upon Japan's tough *juku* (private cramming school) system, saying that the United States "must have *juku* because the Japanese are so productive".

A horrified Mori then had quickly to explain that the Japanese Government, reflecting growing desires for a more liberal educational system, regards private cramming schools, at which some students spend four hours a night, as an evil produced by the terrible competition for entry to leading universities and high schools, and hopes to do away with them. Later, Bell, well known as a supporter of increased homework in US schools, admitted that he had not actually known what *juku* were but what he really wanted was a longer school day "which is a supervised, studying, tutoring, *juku*-type thing" (*sic*).

The US-Japan council will have its first meeting in Tokyo and will have a special panel looking at problems of science and mathematics education — of particular concern to the United States. Experts from the United Kingdom, France and Germany are also to be invited.

Shortly before Mori's meeting with Bell, Japan's Prime Minister, Yasuhiro Nakasone, finally succeeded, after six months of Diet wrangling (see *Nature* **308**, 678 and **309**, 739; 1984), in inaugurating the special council which is to spend three years devising reforms of Japan's education system.

Despite vociferous protests from the socialist and communist parties, the council has been handpicked by Nakasone and is answerable directly to him. Only two school-teachers are among the council's 25 members (average age 60) and there are no representatives from the nation's biggest teachers' organization, the Japan Teachers Union, which virtually ensures that conflict will continue. The post of president of the council has, however, gone to a well known liberal, Professor Michio Okamoto, until recently president of Kyoto University. Nakasone has asked the council to take speedy action on the biggest problem — the university entrance examination — and to seek "diversity" in the education system.

Exactly what diversity means is likely to cause considerable debate. In the present straight "one-track" educational system, completely unstreamed groups study the same subjects and try the same examinations, with only total scores deciding how a distinguished university faculty can be entered (and thus often what subject is studied). The liberals would replace it with one in which students have freedom to follow their own interests and receive an education tailored to their own particular abilities, but what the left wing fears is that "diversity" will simply mean increasing the scale of divisions between top quality (and expensive) private schools and the poorer state schools: an effective return to a pre-war system where elites were selected for special training at an early age.

Japanese universities

Broadcasting for degrees

Tokyo

JAPAN'S first broadcasting university — the University of the Air (Hoso Daigaku) — is poised to go into action: its buildings and facilities are just being completed in Chiba City, near Tokyo, after an initial expenditure of 10,000 million yen (US$420 million). Application forms for the enrolment of its first 10,000 students will be available in a few weeks. Test broadcasts will start at the same time, beginning with programmes explaining what the university has to offer and how to apply for entry.

Once in full operation in April next year, the University of the Air will become the first broadcasting university in the world to have its own specially dedicated television and radio channels, each carrying lectures from 6 a.m. to midnight seven days a week. Adding to this generous helping of learning the 18 hours of school, documentary and language programmes broadcast each day by the national television corporation (NHK)'s Channel 3, there will be a little over 250 hours of television tuition available each week — enough, perhaps to satisfy even the Japanese thirst for education. The university's programmes will, however, be available only to those in the area around Tokyo, for plans to broadcast directly by satellite fell through and conventional transmitters are being used; the rest of the country will have to wait another five years for the service.

Support for the establishment of a broadcasting university resulted partly from the calls for fundamental educational reform after the 1960s student unrest. At Tokyo University, the centre of the trouble, teaching was totally disrupted, the entrance examinations had to be cancelled (losing a year's student intake) and the general public were treated to television coverage of the nation's young elite flinging "Molotov cocktails" from the university tower at riot police below.

With the ending of the troubles, no fundamental reform of university education was carried out, but some new educational projects did get under way: the new "American" style university at Tsukuba (see *Nature* **305**, 371; 1983); a pair of colleges to which school-teachers can return for two years of "refresher" graduate-level training at the government's expense (provided they can pass the tough entrance examination) and, now, the University of the Air.

Despite the Y10,000 million government expenditure on the university and the fact that the Ministry of Education, Culture and Science (MESC) will pay its operating budget, the government will have no direct legal control over the university, for Japanese law guarantees independence of the mass media. Instead, the university is run by a foundation, and its staff, unlike those of a normal university, will not be civil servants.

And although the university buildings are right alongside a new National Centre for the Development of Broadcasting Education, a part of MESC from which the university is renting its broadcasting studios, the university building has been kept just a few metres away to demonstrate its separateness. Only a corridor connects the two. But this arrangement has not fully satisfied the socialist opposition parties, and courses such as sociology and education which can encourage critical thinking about government policy are certain to be carefully watched.

The overall teaching system has much in common with other broadcasting universities. Set texts accompany lectures which are broadcast several times a week at different times of day, tests and reports are sent by mail and face-to-face teaching and end of term examinations given at six regional study centres. Success in the examinations gains credits towards the 124-credit total, and minimum of four years' study, needed to gain a degree. A typical two-credit course requires the understanding of a 120-page book and 15 accompanying 45-minute lectures: it is expected that students will average five broadcast lectures a week plus three hours of lectures at study centres.

Three main disciplines are to be offered: science in everyday life, industrial and social studies, and humanities and natural sciences, but within this framework there is to be considerable choice of specialized subjects after fundamental studies have been completed. Of the 10,000 students to be enrolled to begin with, 4,000 are expected to take a degree course (high-school graduation is the only requirement) and the remainder to take a few subjects for a short period. A full degree course will not be free, although at a total cost of Y750,000 ($3,000) it will be cheap compared with attendance at a university.

Around 50 professors have been chosen to run the university and will be backed up by an equal number of associate and assistant professors. Not having civil servant status, however, the junior staff will be employed on renewable five-year contracts rather than given tenure. Some 100 guest lecturers will also be brought in from other universities on contract to make particular television and radio programmes.

Efforts will be made to ensure that the University of the Air degree is a real degree and not a second-class qualification. To this end, the university is now trying to arrange for credits to be transferable to and from other universities. If this proves successful, given the notorious lack of interchange of students between conventional universities, it will be a remarkable achievement in its own right.

Alun Anderson

US basic research

Cheer and gloom at war

Washington

SHARPLY contrasting views on US university research were aired at a meeting held last week by the American Council on Education. Dr Edward David Jr, president of Exxon Research and Engineering and a former presidential science adviser, told the conference, held at the University of Georgia at Athens, that the growing links between university research and industry were "a promising picture for the future". But Professor William McElroy, professor of biology at the University of California at San Diego, said universities were facing "almost a disaster" in research support.

In his opening speech, David argued that the public's desire to create jobs based on new science, together with the power of new instruments, will lead to more cooperation between universities and private research institutions: industry has been the fastest growing source of support for university research since 1970. But David was concerned that manpower competition from large federal projects in defence and space might crowd out the civilian sector.

McElroy said bluntly that such optimistic views "do not stand up against the facts". Despite constant-dollar increases in federal university research support since 1972, the escalating cost of doing research has meant that the same money now buys less. The amount spent per grant has decreased substantially, and it is becoming harder to find money for research projects: five years ago, a merit rank of 3 on a scale from 1 to 5 would have been sufficient to ensure support from the National Institutes of Health, but now a rank of 1.5 would be insufficient. And McElroy commented that industrial support for university research is concentrated in relatively few universities.

McElroy's remarks echo comments made recently by Donald Kennedy, president of Stanford University, in a letter to Dr George Keyworth, director of the White House Office of Science and Technology Policy. Kennedy wrote that undercapitalization of teaching and research laboratories is causing problems in retaining faculty, while the need for renovations of research facilities had "reached crisis proportions".

University research is the subject of a major study nearing completion in the White House science office, chaired by David Packard, president of Hewlett-Packard. The study is rumoured to back the case for more generous support of basic science by federal agencies. And the Department of Defense is already preparing to step up its programme of unclassified research in universities.

Tim Beardsley

British geology

Strategic survey grinding to halt

GEOLOGICAL surveying of Britain by the British Geological Survey (BGS) has almost ground to a halt this year. Because of over-dependence on short-term contracts and the cost of its recent centralization at a site in Keyworth, Nottinghamshire, strategic surveys of land are running at only 30 per cent of last year's activity.

At the same time, BGS seems to have lost its old friends. Private industry is complaining about its function and performance, BGS has no long-term commitment from government departments that use its services and, unlike most national surveys, it has no direct responsibility to a government minister for strategic surveys and information management. With its parent body, the Natural Environment Research Council (NERC), itself under severe financial pressure, BGS has an uncertain future.

The decline of the land survey activities comes at a bad time. Since 1835, BGS and its predecessors have been preparing geological maps of the United Kingdom at 1:50,000 scale (1 inch to 1 mile), with more detailed mapping following later. Although most of the United Kingdom has been mapped at 1:50,000, at least 25 per cent of the maps are obsolete, according to BGS. Moreover, at the more detailed 1:10,000 scale, large areas of the country remain unmapped, partly because of concentration on regions important for economic or development reasons.

After the survey was attached to the newly-formed NERC, in 1965, it accumulated a wide range of new responsibilities: overseas activities, geochemistry, geophysics, seismology, geomagnetism, mineral and water resources. When, in 1973, the Rothschild "customer–contractor" principle was accepted by the British Government, a portion of BGS funds were transferred to government departments. By 1979, the land survey activites were financed and controlled by a consortium — 60 per cent NERC, 30 per cent Department of Environment, 5 per cent Department of Trade and Industry, 5 per cent Department of Energy. Meanwhile, other parts of the survey were so heavily engaged on commissioned work that three quarters of the survey's funds came from the customer departments.

Although cutbacks by government departments began in 1980, the first major blow to the land survey was struck in 1982 when the Department of the Environment withdrew from the consortium as well as from other activities, replacing that commitment by a series of short-term (six months) contracts whose allocations were not made until after the start of the financial year. The Department of Energy, meanwhile, transferred its consortium support to deep geological research related to onshore hydrocarbons assessment.

These developments left the land survey almost entirely dependent on NERC. The latest blow, earlier this year, was a cut by NERC in BGS science funds of £1 million (about 10 per cent) made necessary because of NERC's severe financial shortage. Because short-term BGS commissioned contracts draw on this science budget, and because the recent move to Keyworth has entailed relocation expenses, the result has been a 70 per cent decrease in the funds available for scientific work. Now, routine activities such as geomagnetic monitoring are threatened while the land survey programme has been curtailed to 30 per cent of last year's when, according to the director of BGS, Professor Malcolm Brown, this programme needed to be doubled.

BGS budget £ million 1984–85 prices

		1982 –83	1983 –84	1984 –85
NERC	Science Vote	63.1	65.1	65.9
	Commissioned income	30.8	26.4	23.7
BGS	Science Vote	9.8	10.4	9.2
	Commissioned	18.5	16.9	14.9

BGS Staff numbers:
1973: 757 **1979:** 1,156 **1985** Target: 920

There are those, inside and outside BGS, who conclude from this catalogue of misfortune that the Rothschild system was the biggest disaster to hit the survey since its foundation. There are others who say that BGS's problems are more fundamental.

Perhaps the strongest criticisms come from local government and private industry, which charge that the survey is simply not providing an adequate supply of basic geological information needed for planning purposes, for example. And the move to Keyworth will exacerbate the situation, the critics say, by rendering the available information less accessible. But BGS intends to maintain its London library until 1986 at least, and thereafter to maintain a London information centre with two BGS scientists and a duplicate supply of key geological maps and reports.

Many of the private companies are deeply irked that, as they maintain, BGS is in effect a state-subsidized competitor for short-term contracts which is too heavily engaged in such work to provide British industry with basic services. It is hard to document the charge, but staff at BGS concede that customers will tend to benefit from the large infrastructure available to support contracts placed with BGS.

Staff at BGS are all too aware of the backlog in the publication of maps and memoranda. One explanation is the diversion of resources and funds to other activities. It is estimated that one map at 1:50,000 scale now requires anything up to £1 million to produce from scratch. In fact, the survey has about 50 geological memoirs in preparation, some of which might be published for as little as £20,000, but the money cannot be found.

Another contributory factor, put forward by a visiting group commissioned by NERC to assess BGS, is that while the collapse of the land survey consortium was much to blame, BGS administration of the preparation of reports and maps was inadequate — a charge also made by the previous visiting group a few years earlier. A long-term response to such criticisms, but one of BGS's top priorities, is the establishment of a national computerized database — a massive task, particularly now that strategic surveys use geophysical as well as geological techniques to prepare maps.

Complaints against BGS are offset by industry's acknowledgement of the value of services such as the provision of minerals intelligence and general commodity expertise. In 1981, minerals and quarrying (including oil) accounted for 18 per cent of UK production, and BGS supplies information ranging from distributions of potash horizons based on North Sea drilling to details of small barytes mines.

Ultimate — and, in many people's opinion, excessive — control of BGS rests with NERC. Academic geologists and those working for other national surveys are surprised, even outraged that the director of BGS has to refer to NERC headquarters each new appointment to his staff, for instance. Similarly, every decision relating to the purchase of computing equipment is referred to NERC's central division. Coincidentally, computing problems have been highlighted by a decision by the Department of Energy to cancel its contract with NERC for computing services associated with its continental shelf programme, and by a recent internal NERC report which recommended some decentralization of computing power.

NERC says its control of manpower, budget and the scientific programme of BGS stems from its accountability to Parliament. But NERC is aware of the backlog in the preparation of maps and memoranda, and has proposed that resources might be diverted within BGS for the work.

In short, there is general agreement that the function of BGS which is most in demand — the provision of basic information about the geology and natural resources of the United Kingdom — has, for a number of reasons, virtually fallen by the wayside. Some members of other national surveys suggest that BGS should be wrested from NERC and made responsible to a "minister for natural resources". As no such post exists in the United Kingdom at present, this radical proposal is unlikely to be realized, at least unless NERC itself is disbanded. Given the tight budgets within which BGS is operating, however, it is hard to see that a simple redistribution of its internal resources can have a significant impact on a central problem.

Philip Campbell & Peter Gambles

UK atomic energy

Putting research out to contract

THE UK Atomic Energy Authority (AEA) may soon be dead, but long live atomic energy in the United Kingdom. That seems to have been the mood at Britain's nuclear establishments last week, in the wake of the publication a week ago of a set of proposals for reorganization that will eventually saddle electricity consumers and other users with much of the cost of applied research in nuclear energy.

The new arrangements have been put to the Secretary of State for Energy, Mr Peter Walker, by an anonymous committee of officials from the department. The good news for AEA is that the committee has shrunk back from the notions that the authority should be dispensed with ("an authoritative body of expertise . . . will continue to be required") or transferred to the private sector (which is "not realistic").

Big changes are nevertheless intended. The committee recommends that a greater share of AEA's research should be paid for by the electricity industry, and that other research commissioned by the Department of Energy should be paid for on the "customer-contractor" basis.

The case for some continuing support for nuclear research is that the "government's policy that [Britain] should have a significant nuclear power programme for the foreseeable future" makes some kind of research programme necessary, while the "unique nature of nuclear power and public perceptions of it" will require continuing public support for programmes of research going beyond strictly commercial interests.

On the authority's specific research programmes, the official committee recommends that the electricity industry should shoulder a larger proportion of the cost of fast reactor design as research gives way to development, that work on thermal reactors should be paid for exclusively by the electricity generators, that there should be further discussion about sharing the cost of nuclear safety research, but that the nuclear waste programme should continue to be paid for centrally.

The committee says that the "underlying programme" of research has been of benefit to user organizations but that, on the principle that present customers are "proxies for future customers", they should now begin to contribute towards the cost of this research.

The next step in the unwinding of AEA's dependence on public funds is that the minister should decide whether to accept the proposals his officials have put to him, which will in turn depend on negotiations between the potential customers (which may be unwilling to pay for service hitherto free) and the potential contractor (which may also be an unwilling partner).

The Department of Energy is nevertheless hoping that the outstanding issues of who pays what will be settled within a few months, which would have the advantage that much of the cost of the British nuclear research programme would disappear from the government's expenditure accounts before the beginning of the next financial year in April. Another specific recommendation of the committee, which has been generally accepted, is that AEA should in future be managed as a "trading fund", a public corporation subject to the accounting rules that apply to private companies (and carrying the freedom to borrow from the banks). But this arrangement will require legislation, so the formalities are likely to be delayed.

In the authority, officials and staff members say they "have seen this coming for a long time". There are grounds for optimism that, in the short run, the authority (which already supports a third of the research at its largest establishment at Harwell through outside contracts) will be able to maintain the present level of activity. The dangers may come later, when customers for its research services may spend their contract money on quite different things. ☐

UNESCO

One friend for M'Bow

MR Amadou-Mahtar M'Bow, director-general of the United Nations Educational, Scientific and Cultural Organization (UNESCO), went last week to Strasbourg to defend his beleaguered organization's record before the Assembly of the Council of Europe. And while he had little success in convincing delegates that UNESCO's house is in order, the Council of Europe agreed that its secretariat should go ahead with plans to increase cooperation between the two organizations.

This move may stem from a fraternal feeling between UNESCO and the Council, both of which were set up after the Second World War as institutional symbols of peace and goodwill. Now UNESCO is in trouble, accused of mismanagement, and threatened with the withdrawal of the United States, the Council wishes to come to its aid. In fact, there have been regular contacts between the two organizations since 1952, when the first cooperation agreement was signed, and the plans in hand are merely to extend the contacts a little. The new agreement is to cover areas of common interest such as communications (satellites and copyright questions), cultural development and North-South cooperation. The vexed issue of "a new world information order" for news reporting is not among topics for discussion.

Even so, the mere presence of M'Bow at the Council's building in Strasbourg was too much for conservative group members of the assembly, who issued a declaration deploring the invitation to him. But this need not deter M'Bow from returning later this month, when the plans for extended cooperation will be on the agenda.

At the assembly last week, M'Bow had to field questions on the morale of UNESCO staff; on the American General Accounting Office report which attacked UNESCO spending and 70-per-cent overheads; on the political nature of a UNESCO mission to Afghanistan; and on the "new world information order". The conclusion: that the UNESCO crisis is "very deep", said an observer.

Nevertheless M'Bow may count the meeting a success if increased cooperation between the Council and UNESCO does materialize. The 21 Council of Europe states between them pay 33 per cent of UNESCO's budget. The United States pays only a quarter. **Robert Walgate**

Australian array

Canberra

CONSTRUCTION work has begun at Culgoora, New South Wales (NSW), on the $A32 million Australia Telescope, which, if ultimately linked with other Australian radio antennas, would possess a baseline thousands of kilometres across, making it complementary to the large radio arrays planned in the Northern Hemisphere.

The Australia Telescope will comprise two arrays of individual radiotelescopes. The Compact Array will consist of six mobile antennas each of 22 metres diameter and locatable at 37 stations along a 6-km east-west line at Culgoora. The Long Baseline Array will combine the 64-metre radiotelescope at Parkes (NSW) with one or more of the Compact Array antennas and a seventh 22-metre antenna at Siding Spring (NSW). Its 319-km baseline will permit an angular resolution of 0.02 second of arc at a frequency of 10 gigahertz, a performance that could be improved on by linkage to telescopes at Fleurs, Hobart, Alice Springs and Carnarvon, and to the 64-metre radiotelescope of the National Aeronautics and Space Administration at Tidbinbilla, which is already linked with Parkes in preparation for the 1986 Voyager fly-by of Uranus.

Approximately half the overall capital cost will be taken up by the new Cassegrain antennas, which will incorporate feed horns designed for simultaneous observation in more than one frequency band. Both arrays are due for completion by 1988, and will be operated as a national facility by the Radiophysics Division of the Commonwealth Scientific and Industrial Research Organization (CSIRO).

Jeffrey Sellar

Italy

New hope for research council

SCIENTIFIC hearts are beating faster in Italy this week, as real hopes emerge of genuine reform of Italy's major but chaotic research council, the Consiglio Nazionale delle Ricerche (CNR). Last week the Italian Parliament ended eight years of colourful Neapolitan presidency of CNR by appointing a dynamic Milanese enzymologist, Professor Luigi Rossi Bernardi, to the next four-year presidential term. With Rossi Bernardi at the helm, the control of CNR passes from the underdeveloped south of Italy to the better-organized and industrial north: certainly the most fundamental event in Italian science politics for some time.

However, Rossi Bernardi is fully aware of the magnitude of his task. "Don't promise too much", he warned last week. Rossi Bernardi knows CNR from inside as a past president of the CNR medicine and biology committee. He identifies the key issue as that of quality: the proper allocation of resources, posts and promotions on the basis of scientific merit rather than custom or seniority. This means confronting interests, inevitably a political job. But Rossi Bernardi has powerful political friends, in the socialist prime minister Bettino Craxi, in the Christian Democrat research minister Luigi Granelli (both Milanese) and in the Christian Democrat party itself (which nominated him). He belongs to no political party, and says he will manage CNR "as a scientist", with the sole objective of improving the quality of CNR-supported science; but it will certainly be no hindrance to him to have friends in the right places. It will help also, said a colleague, that he comes from a medical department, medics being "the strongest mafia — in the best sense — in the Italian universities".

Rossi Bernardi is regarded as a proven organizer, both in his earlier work at CNR and his department in Milan. He is not greatly concerned, he says, with the total budget of CNR — which will grow 10 per cent next year, roughly in line with inflation. "The real problem is how the money is spent", he says.

Rossi Bernardi must also cut through the usual trip-wires with which Italian administration likes to entangle itself, such as a law recently passed which allows CNR institutes (and other state organizations) to hold as fluid funds only four per cent of their annual budgets, the rest remaining in the state treasury. The rule was originally designed to stop misappropriation, but its effect has been catastrophic, as CNR institutes are now having to request additional funds almost weekly from Rome. "We are at a standstill all over Italy", says one Naples biologist.

Another problem facing Rossi Bernardi is the fact that something like half of all CNR scientists have published nothing for five years (according to a survey he instituted two years ago). And the council languishes under a law which treats scientists as the most routine kind of civil servant, inhibiting promotion on merit (substituting seniority) and all but forbidding appointments into CNR at high level (as laboratory directors, for example). "It's a very, very hard job", says Rossi Bernardi.

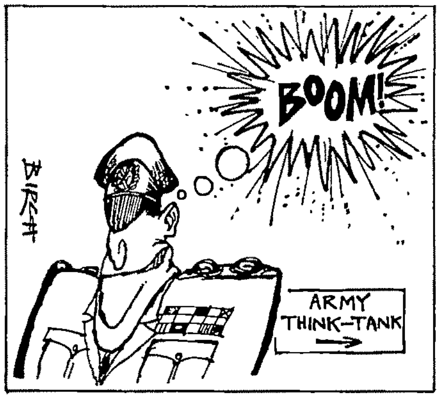
Robert Walgate

US Army research

Expelled think-tank finds Rand

Los Angeles

THE US Army's new think-tank, given the cold shoulder by faculty of the California Institute of Technology earlier this year, has at last found a home. Within the next few months, the Arroyo Center will move from its present quarters at the Jet Propulsion Laboratory (JPL, administered by Caltech) to the Rand Corporation, located in another part of greater Los Angeles.



Rand has been home to the US Air Force's think-tank since the Second World War. "We don't see that there's a conflict", said Donald Rice, Rand's president and chief executive officer, who said that "for decades" Rand has been working for both the Air Force and the office of the Secretary of Defense as well as several other components of the Department of Defense, the Army and the Navy included.

Both the Navy and the Air Force have independent think-tanks, and the Army two years ago decided that it also needed one. The centre's charter is to examine long-term issues involving defence strategies, military operations, resource management and advanced technology as they affect the future Army.

As the centre began to set up shop last spring under Caltech's wing, the faculty balked. A majority said it was inappropriate for the university to lend its name and reputation to an organization that would lobby on behalf of military interests. Although it was acknowledged that many faculty members work on defence matters, it was argued that the university as a whole should not.

Caltech president, Marvin Goldberger, was criticized, but quickly forgiven, for having let the arrangement take place without prior faculty approval. The centre was moved to the nearby JPL campus and asked to look for another home.

At Rand, the Arroya Center will become a fifth division joining Project Air Force and other national security research, domestic research and the Institute for Civil Justice.

Persistence of miracles

SIR — A leading article in *Nature* (19 July, p. 171), quite rightly questioned whether "science has nothing to say" on the subject of miracles; but it was surely wrong in attributing to science the dogma that "miracles do not occur". In scientific laws we describe, as best we can, the pattern of precedent we observe in the sequence of natural events. While our laws do not prescribe what must happen, they do prescribe what we ought to expect on the basis of *precedent*. If by a "miracle" we mean an unprecedented event (and the resurrection of Christ is certainly described as such), then science says that miracles ought not to be expected on the basis of precedent. What science does not (and cannot) say, of course, is that the unprecedented does not (or cannot) occur.

If, as Christians have traditionally believed, the whole spatio-temporal sequence of events that make up our world owes its being to our Creator, then it is thanks to Him that our scientific explanations normally prove as reliable as they do. But by the same token, nothing whatever in our observations of "normal precedent" can make it impossible for the Creator to bring about a totally unprecedented event, if His overall purpose for His creation requires it. Christians believe that the resurrection of Christ was just such an event. We do no good to the cause of science by pretending that there are scientific grounds for denying that it could have happened.

To say this, however, is not to suggest that we should go soft on "mischievous reports of all things paranormal, from ghosts to flying saucers", as *Nature*'s leader writer seemed to fear. For the Christian believer, baseless credulity is a sin — a disservice to the God of truth. His belief in the resurrection does not stem from softness in his standards of evidence, but rather from the coherence with which (as he sees it) that particular unprecedented event fits into and makes sense of a great mass of data. Some of these data are historical, some derived from the cumulative experience of Christians down the ages, including himself. So his faith is not groundless. There is clearly no inconsistency in believing (with astonishment) in a unique event so well attested, while remaining unconvinced by spectacular stories of "paranormal" occurrences that lack any comparable support.

Both wishful thinking and wishful unthinking are evils, and it will not do to tumble into one for fear of the other. We cannot dogmatically exclude the ever-present possibility that the truth about our world is stranger than we have imagined.

DONALD M. MACKAY
*Department of Communications
and Neuroscience,
University of Keele,
Keele, Staffordshire ST5 5BG, UK*

SIR — Your leading article "Miracles do not happen" (*Nature* 19 July, p.171) appears to contradict itself at least twice. First you urge critical rigour for evaluating a particular miracle, the turning of water into wine by Jesus. I agree. But then you baldly state: "Miracles... do not occur — a definition by exclusion of the concept". You apparently mean that they are excluded from all factual discourse, not just from science, since the latter would be agreeing with the very notion you wish to oppose — that science has nothing to say about miracles. Finally, you state that religious belief "on other grounds" is unexceptionable.

But why insist on critical rigour for evaluating particular miracles, if *by definition* they do not occur? And how can you find religious belief "unexceptionable" if you deny (by definition!) some of its key tenets. It is not only the grounds of belief that are at issue here, but the content.

Your concern not to license "mischievous reports of all things paranormal" is no doubt motivated in the interest of scientific truth, but your strategy of defining away what you find unpalatable is the antithesis of scientific. It is disheartening that *Nature* should sell its empiricist birthright for the stale soup of *a priori* rationalism.

P.G.H. CLARKE
*Institut d'Anatomie,
Rue du Bugnon 9,
1011 Lausanne, Switzerland.*

SIR — Jeremy Marshall (*Nature* 30 August, p. 722) would like scientists to behave themselves and stop questioning miracles, as a sort of act of gratitude for his consent to "believe that evolution has occurred". He objects to scientists concerning themselves with miracles because this subject "is outside the bounds of proper scientific inquiry".

Unfortunately, miracles are sometimes invoked to explain natural phenomena on a nonscientific basis. Creationists have been particularly adept in the use of this device. Conclusions about miracles have been repeatedly reached by scientists on a scientific basis, and are not necessarily an invasion of theology. In turn, scientific inquiry into natural phenomena often reveals facts that seem sufficiently miraculous to excite admiration and awe from scientists and theologians alike.

THOMAS H. JUKES
*University of California,
Berkeley, California 94720, USA*

BioNet and GenBank

SIR — A few points in your recent news article "Limited access to BioNet" (30 August, p. 717) require clarification. The article confuses two separate projects funded by the US Government: the GenBank project, which is the national genetic sequence data bank in the United States funded by several institutes of the National Institutes of Health (NIH) and other government agencies; and BioNet, a computing resource for molecular biologists also supported by NIH.

GenBank is a contract jointly run by the Los Alamos National Laboratory and Bolt Beranek and Newman, Inc. to collect, maintain, distribute and provide computer access to nucleic acid sequences and related data. It is this work which is performed in close collaboration with the parallel effort here at EMBL in Heidelberg. The task of data collection is in fact shared between the EMBL and GenBank groups, and data are exchanged on a regular and unrestricted basis.

BioNet is a project managed by Intelligenetics, Inc. to provide molecular biologists with computing resources, including analysis software, communications facilities, and databases accessible by computer network. (Two of the databases so provided are those produced by the GenBank and EMBL efforts.) Limitations on BioNet access are necessary because it is, at present, implemented on a single computer of finite capacity.

It should be stressed that these limitations apply to use of the BioNet computing facility, not to availability of the GenBank and EMBL databases. Both databases are available worldwide, in various forms, to anyone.

Nuclear power

SIR — J.R. Ravetz complains (*Nature* 9 August, p. 446) that *Nuclear Power Technology*, reviewed by Sir Alan Cottrell (*Nature* **309**, 545; 1984), contains no reference to weapons technology. As deputy editor of that book I should explain that it is about nuclear power technology, not nuclear weapons technology.

While nuclear power stations and some nuclear weapons draw their energy from the same fundamental phenomenon, namely nuclear fission, the staff of the Atomic Energy Authority, by whom the material for the book was written, are not competent to write about nuclear weapons.

I am sure Mr Ravetz would not expect to see high explosives technology discussed in a book on oil-fired power stations, although the energy source is common to both.

Ethics, ethical committees and animal experimentation

from David Britt

Will the establishment of local review committees for animal experiments in Britain modify attitudes of researchers and the public?

THREE years ago, editorial comment in this journal advocated the establishment of institutional committees to scrutinize proposals for experiments on animals in a way that has proved useful in the regulation of genetic manipulation and research involving human subjects (*Nature* **293**, 173-174; 1981). The committees were seen as a means of bringing together persons with differing views on animal use in an attempt to resolve practical issues of animal experimentation in a less arbitrary manner than legislation seemed to offer. Correspondence on the subject published in subsequent issues revealed a favourable reaction to the idea but this has not been translated into a rush to set up such committees in the United Kingdom. Many British research institutions have committees devoted to the supervision of laboratory animal facilities but few, if any, of these consider the ethics of proposed animal usage and are therefore avoiding the issues which the *Nature* editorial wished to see addressed.

There is a notable reluctance among British scientists to discuss the moral implications of animal experimentation, possibly because, by and large, they are uncomfortable in the area of philosophical (especially ethical) debate. As long as their work is within the law, what research scientists do is very much their own responsibility and perhaps ethical issues are a matter for individual conscience rather than open debate? The growing interest and concern of a broad section of the rational general public renders this position untenable today. Some scientists have the arrogant notion that only they can fully appreciate and weigh the issues, so that discussion with others is pointless. Other scientists and scientific administrators apparently entertain the hope that by adopting a 'low profile' approach to public concern, it will fade away. In each case the scientific community is denying any responsibility to be accountable to the public for its actions and activity.

At an individual level, is there also, perhaps, an underlying fear that too deep a questioning may reveal to the scientist the weakness of the philosophical basis on which his current, permissive position is founded?

Elsewhere in the world, scientists have been less inhibited in the debate on the ethics of using animals in experimentation and have even invited participation by the public at large. One reason often advanced for the lack of similar initiatives here is that some proponents of animal rights issues have adopted illegal, even violent, means to further their cause and thus alienated themselves from rational opinion. However, it is quite wrong to suppose that the same spectrum of personal attitudes to animal experimentation is not to be found elsewhere, even if the practical expression of extreme views antagonistic to research on animals is qualitatively different. Why this difference exists offers a fascinating area for study in social psychology, but the present situation in Britain may not be totally unrelated to the aloofness and conservatism of our scientific establishment. It is time for scientists involved in research with animals to confide in, and consult with, the general public — at least those sections of it which can be objective while maintaining a genuine concern that unnecessary suffering should not be inflicted.

If introduced to British research institutions, animal experiment review committees would assist in establishing a valuable dialogue between scientists and the lay public. Further, they would provide the scientific community with the chance to reveal its own concern for the welfare of laboratory animals and their humane, non-profligate use, thus allaying public disquiet, often fanned by inaccurate, emotional propaganda from extremist sources. Lay input might encourage scientists to be more reflective in their management and use of animals and in experimental procedures. This has happened in Sweden, for example, without discouragement of worthwhile scientific investigation.

Ethical review in Sweden

In July 1979, local ethical committees for the review of animal experiments became mandatory in Sweden. Six committees were established, one for each of the country's University regions, to cover experiments in all research institutions using laboratory animals: academic, government and commercial. An additional committee was formed to review experiments on animals to be conducted by the military authorities, with members screened for security purposes. All the committees were made responsible to a board of the Ministry of Agriculture which still regulates the scheme and provides a secretariat and funds for essential expenses of committee members. Membership of the committees comprises equal numbers of individuals from three categories: research scientists, animal/laboratory technicians and lay persons. The sanctioning of such a high degree of participation by the general public is one of the boldest (some would argue, most reckless) aspects of the scheme. The largest committees, at Stockholm and Uppsala, have total memberships of 45, the smallest only 15. Volunteer scientist and technician members are solicited from all relevant institutions in each region; the lay members are nominated by animal welfare societies or local government agencies.

From the outset, attempts were made to ensure that the creation of an unwieldy bureaucratic monster would be avoided. Two aspects of committee organization have helped to achieve this. First, all experiments are graded (initially on a five-point scale, later simplified to two) for the degree of animal suffering likely to be imposed, and application for review is essential only for those, a minority, in which significant suffering is envisaged. In this way, the workload of the committee remains manageable. However, details of all experiments involving animals are notified to the committee, which may disagree with the grading. Second, each experimental protocol for review is discussed by the investigator and a subcommittee of only three members — one from each category — and referral of the project to consideration by the full committee is only necessary if agreement cannot be reached by the small group. Details of all projects submitted for review and sub-committee decisions are made available to all committee members. It is usual for the full committee to meet only two or three times a year.

Generally, reaction among scientists is favourable although the consensus is that the maximum usefulness of the committees has yet to be realized. There are criticisms that the three-year trial period in Uppsala was inadequate to allow potential problems to be identified and complaints that the decision to introduce review committees on a national basis was inspired more by political expediency than by scientific or humanitarian aims.

Scientific members of the committees are recruited from among the most experienced and senior research personnel. Such individuals are frequently overburdened with meetings of committees of various kinds. Any change which threatens to increase the time to be allocated to the work of the ethical committees will deter recruitment but this may be offset as the committees grow in influence and prestige.

Technician members have been accused by anti-vivisectionist groups in the country of refraining from expressing criticism of research proposals through timidity. Where the technicians feel themselves to be in a subordinate role to the scientists there may be truth in this accusation. On the other hand, many scientists and lay members of the committees of more moderate persuasion, feel that technician representatives have a vital contribution to make through their intimate knowledge of experimental procedures and good practice in animal care, often helping the committees to frame improvements to protocols.

Lay persons volunteering for membership of the committees have a concern for animal welfare in common but differ in their attitudes to animal experimentation. Some are unable to accept that there is any justification for the use of animals in biomedical research. It is difficult to understand why these individuals elect to serve on committees responsible, ultimately, for sanctioning animal experiments — at least those which are thoughtful, well-designed and both sparing and humane in their use of animals. Because they seek nothing less than the total abolition of experiments involving animals, anti-vivisectionists must remain frustrated by the activities of the committees. If they are members of one of the committees, their philosophical position demands that they must withhold consent from any protocol, even one which may have been improved at the recommendation of fellow members to ensure greater humanity in the treatment of animals. If their wish is to disrupt research effort, this also is frustrated, because all they can hope to achieve is a prolongation of debate in committee and delay in the onset of experiments before a majority decision allows the work to proceed.

Regrettably, ethical review committees in Sweden are presently facing serious problems. It is proving difficult to obtain suitable volunteers for membership and meetings are not always well attended. This is a serious indictment of the system because it suggests that the work of the committees is not highly valued. The problem has been exacerbated by the action of anti-vivisectionist members who have caused more and more lengthy, and circular, debate and prolonged meetings.

Proposals for radical reform of the system are currently being investigated by the Swedish Ministry of Agriculture. Included is a recommendation that each committee should be limited to a total of nine persons, the same three categories of membership to be retained but each with only three representatives. This is seen as a means of reducing administrative costs and overcoming problems of recruitment as well as facilitating the arrangement of meetings, but the idea attracts little support outside the Ministry except in so far as it promises to squeeze out participation by anti-vivisectionists. It is unlikely that this small committee could be representative of all relevant institutions within each University region and the necessary reduction in range of expertise available for consultation would also be detrimental. Because anti-vivisectionist groups wield considerable political influence in Sweden, attempts to exclude them from the committees may well be unsuccessful.

Professor Karl Johan Öbrink from the Biomedical Centre at Uppsala, one of the chief architects of the ethical review system, is also concerned about the present state of the committees and their future. He is critical of the emphasis on control which has become dominant with the codifying of the system in law and since administration of the committees became the responsibility of the Ministry of Agriculture Board. As originally conceived, the committees were to be advisory bodies encouraging consultation between investigators and other experts, with the aim of securing improvements in research design and ensuring the rational, humane use of experimental animals. In spite of misgivings about present arrangements, he remains totally convinced of the value of this kind of ethical review.

There was controversy earlier this year when a technician representative on the committee serving the Lund/Malmö region resigned after complaining that the committee system was powerless in offering protection to animals and implying that some scientists were unnecessarily callous in their use of experimental animals. This individual holds a responsible position within the University of Lund and is respected for his knowledge and experience in laboratory animal science. He is completely opposed to the views of the anti-vivisectionists, who he condemns as being largely responsible for the ineffectiveness of the committees, but, extraordinarily, finds himself advancing arguments which echo those of the opponents of animal research. He believes that the presence of anti-vivisectionists on the committees inhibits scientists and technician members from criticizing protocols which their expert knowledge, experience or intuition persuade them are suspect, because they fear exposure of these criticisms to the media with public discredit to the investigator and institution concerned. Unsound proposals thus pass unchallenged (except, perhaps, by lay members) with the implication that unnecessary suffering may be caused to animals in these investigations. This assertion says little for the moral integrity of the scientists and technicians involved and it also seems odd that by suggesting modifications to unsatisfactory projects the committee should create unfavourable publicity for the scientific community. However, it is conceivable that insensitive media treatment of such incidents might prove damaging.

The greatest threat to the usefulness of the Swedish committees is posed by the strength of the anti-vivisectionist lobby. It is regrettable that, by striving for the unattainable, that is, immediate abolition of the use of animals for experimentation, the anti-vivisectionists are hampering the amelioration of animal suffering that is possible now. The results of this activity in Sweden have wider implications, for the bold gesture which introduced the national system of ethical review as an essential prerequisite for animal experiments has attracted international attention. By reducing the efficiency of the commmittees or threatening their continued existence, the Swedish anti-vivisectionists fuel critics of the scheme elsewhere who are anxious to discredit the initiative in an effort to prevent the introduction of similar schemes in their own countries.

Review in North America

In the United States scientists are currently attempting to come to terms with new guidelines on laboratory animal welfare proposed by the National Institutes of Health (NIH), the major grant-awarding body for biomedical research in the country (*NIH Guide for Grants and Contracts* Vol. 12 No. 5; 1984). One of the major proposals requires the appointment at each research institution of an Animal Research Committee (ARC). It will consider both care and use of animals, and is required to review any research proposal in which animals are likely to be exposed to severe pain or distress. Most controversial is the directive that at least one committee member must be unconnected with the institution — in effect, a representative of the general public.

The commonly held view is that practices recommended in the document could be established before the end of this year and institutions throughout the country are producing plans to ensure conformity with the requirements. Other funding agencies traditionally defer to the NIH in matters of this kind, so failure to comply could deprive a research institution of any money from external sources. The grant-awarding bodies in the United States are the chief arbiters of what research may be carried out there and how. They have set standards which aspiring grantees have had to fulfil, including, for prospective users of experimental animals, standards of animal care and management. However, there have been a few highly publicised incidents of malpractice which suggest that the regulations require strengthening and the new guidelines are, in part at least, a response to this adverse publicity.

Some US research institutions have already, voluntarily, established committees with responsibilities similar to those outlined. A few even have lay members (often representatives of animal welfare societies) but these are exceptional. Their development has been due to the concern and enthusiasm of one or more staff members, not necessarily research scientists themselves. Ethical review was pioneered in America at Colorado State University, Fort Collins, largely through the efforts of Bernard E. Rollin, the forceful professor of philosophy, who developed a keen interest in animal rights issues and taught an ethics course to undergraduate veterinary students. The appreciation of the relevance of considering the morality of Man's use of animals which this engendered has so pervaded the University that concern for the treatment of experimental animals there quite naturally found expression in the careful consideration of experimental protocols by a committee of peers. This committee has not included participation from outside the University but plans are now in hand to change this in line with the NIH requirements.

The veterinary staff at Colorado State University gave good support to Professor Rollin's initiative. In other parts of the United States, laboratory animal veterinarians have since taken a lead in organizing similar review committees, if only to strengthen their own hands in securing improvements in maintenance and use of experimental animals. Generally, however, the veterinary profession has shown little collective concern for animals in research, preferring, as a Washington representative of the American Veterinary Medical Association (AVMA) recently remarked, "to remain neutral on the issue". There is a special AVMA committee on Animal Welfare which includes the welfare of laboratory animals in its remit and a postgraduate Diploma in Laboratory Animal Medicine has been developed which is gaining increasing acceptability as a suitable qualification for veterinarians employed in this young but expanding specialization. However, while there can be no doubt of the commitment of individual members of the profession to the cause of laboratory animal welfare, concerted effort to ensure needed improvements and reform are lacking, as if the profession is unsure of its ground in appearing to criticize colleagues in science or medicine.

One way in which ethical concern for experimental animals is expressed is by ensuring that only competent staff are employed in their care and maintenance. Competence is achieved through experience and training, so the provision of a training course for US veterinarians responsible for experimental animal facilities is a valuable contribution to laboratory animal welfare. The appointment of veterinarians with these specialist skills is a measure of the concern of an institution for the well-being of its animals — as is the minimal or complete lack of veterinary cover found in some large research institutions in the United States and, of course, in other countries.

The training of biomedical researchers in the specific skills of caring for and using experimental animals efficiently and humanely is just as important a consideration but courses are much less formalized, or even non-existent. This deficiency is not unique to the United States.

Potential members of an animal research review committee may also benefit from some training and with remarkable alacrity the Scientists Center for Animal Welfare (SCAW) in Washington has anticipated this in a series of workshops offering help on the setting up and running of the committees along the lines of the NIH proposals. The first of three workshops planned for 1984 was held in Baltimore in May. Eighty-five of the ninety participants who completed a questionnaire after the meeting thought that committee review of research proposals for animal welfare concern was "very important". None opposed review. Most of the respondents were research scientists, veterinarians or animal care technicians. Although the group was highly selected, the survey results provide evidence of a positive attitude among American scientists and their colleagues to Animal Care and Use Committees as an important means of improving laboratory animal welfare.

The NIH recommendations offer potential for such improvement but they present several problems which institutional heads and administrators will have to consider carefully as they formulate their response. Among questions which the planners will need to ask in the context of the individual circumstances of each institution, the following are likely to be significant:

(1) Will the volume of research proposals present the committee with an excessive workload — a distinct possibility in major centres. (If only selected protocols are reviewed, will demand for public accountability be satisfied?)

(2) Will the ARC consider matters of ethical concern only or ethics and scientific merit of the projects? The two are so interconnected — animal research which is badly conceived scientifically is necessarily unethical — that consideration of both seems inevitable.

(3) Will ARC decisions be arrived at by consensus or on a majority vote? (That is, how much influence will the lone, extra-institutional member carry?)

(4) How will the ARC confirm that investigators comply with its decisions? (Will there be any follow-up, reporting back, committee inspections or monitoring procedures?)

(5) Will there be any attempt to standardize ARC policy and criteria for decision making between institutions?

(6) What will be the legal status of ARCs?

(7) Will investigators have a right of appeal against decisions of the ARC?

(8) Concerning the non-institutional member: what kind of person should be selected? What should be the terms of the appointment? Should he/she be remunerated? How can the need for confidentiality be reconciled with conscience to protect (i) the interests of the institution and (ii) the integrity of the lay member.

The current proposals allow research institutions to select the outside member(s), but they will want to appoint persons from the community with sufficient objectivity to be credible as representatives of public opinion.

Several of the problems listed above have already been faced in Sweden and in Canada, where institutional Animal Care Committees have been in existence for several years. In Canada, such committees are a feature of all institutions in which experimental animals are used. Their responsibilities include the sanctioning of all work involving animals (in teaching, field studies, research and trials), ensuring high standards of animal care and the review of research protocols. In Ontario and Alberta, the committees are mandated through provincial legislation. The Canadian Council on Animal Care (CCAC), an authoritative body within the Association of Universities and Colleges in Canada, has recommended terms of reference and guidelines to which the committees conform. Periodically, site visitors are arranged by CCAC to assess the efficiency of each institution's committee and help effect standardization on a federal basis. It is recommended that membership should include lay persons to represent community interests; lay person also serve on assessment panels for site visits. Existing lay members of Animal Care Committees represent major animal welfare societies or are members of professions: law, education, the church. The committees should be primarily concerned with the ethical aspects of the suggested procedures and the property of suggested methodologies, since grant-awarding agencies use peer review to confirm the scientific merits of projects seeking financial support.

The Canadian Federation of Humane Societies, representing 36 member organizations, and somewhat akin to Britain's RSPCA, provides an effective mouthpiece for public animal welfare concerns in Canada. Its view is pragmatic on the issue of using animals in experiments, but there is a growing tendency, within the Federation, to question the continuing need for their use in biomedical research. It is fully supportive of the institutional Animal Care Committees and distributes publications to guide their members.

There is no shortage of animal welfare groups in the United States,one or more of which might adopt a similar role to that of the Canadian Council on Animal Care in providing oversight of the new committees when established, perhaps in conjunction with officers of NIH. Support similar to that provided by the Canadian Federation of Humane Societies would help to ensure the effectiveness of the American committees.

Lessons for Britain?

How relevant is all this to the situation in Britain? It is naive to suppose that a regulatory or advisory system which proves valuable in one country can be transposed to another with similar expectations. Equally, it is foolish to ignore interesting developments in other parts of the world which are relevant to one's own situation. Successes and failures of overseas initiatives can inform and guide the planners of suitable indigenous approaches. This is not to deny that there are major historical, cultural, legislative and logistical differences between the countries included in this discussion which create formidable barriers to the easy exchange of ways of tackling common problems.

One difference which is frequently advanced to suggest that Britain has nothing to learn from groups overseas in respect of animal welfare, is that legislation for the protection of animals in Britain predates that of any other modern State. The importance of this tends to be overemphasized and other nations have not been so tardy as is sometimes supposed. Sweden's first animal protection act, for example, dates back to 1944 and it is arguably more relevant to the present day than the British legislation formulated in 1876, no matter how amenable to reinterpretation that law may have proved.

Because of this misconception — that all other countries are 'starting from scratch' in animal protection — regulations which the latter introduce are interpreted as being nothing more than attempts to bring themselves 'up to our level'. In fact, the practical and philosophical expression of concern for improvements in laboratory animal welfare in countries like Sweden and Canada has outstripped legislative provision here — even if the ethical awareness of some scientists and others involved with laboratory animals in Britain remains as keen as that of their counterparts anywhere in the world.

The present British regulatory system is applauded as a model of rationality and efficiency by some and described as wholly inadequate by others. The latter group includes not only the hard-line opponents of animal experimentation but scientists working within the system. Wherever the truth lies, future Government legislation, based on an appraisal of the current system, promises to significantly tighten controls. But, no matter how stringently the law may be drawn and no matter how rigidly it may be enforced, at the interface between the scientist and his subject, only the attitudes of the scientist are important. A heightened awareness by experimenters of the responsibilities associated with the use of animals and increased sensitivity to their needs and their capacity to suffer will achieve much more for laboratory animal welfare than new legislative measures (although legislation to encourage the introduction of institutional review bodies here to help achieve these desirable changes would seem appropriate!). These were the kind of thoughts which prompted the Uppsala experiment and which make the Fort Collins initiative so important, where the ethos of these institutions has developed to permit the expression of a rational, caring approach to the use of animals in research.

The committees in Sweden and North America (existing and planned) are answerable directly to the institution chief or administrative head and contain very senior staff as members. As a tangible benefit to the institution, they provide an important public relations service by ensuring compliance by institution personnel with existing national and local regulations on the care and the use of experimental animals. Beyond this, they provide a guarantee that only 'clean' work is undertaken, this assessment having been reached not merely by the scientists alone. The attraction of such guarantees to institution chiefs is obvious and, equally, it is important to the prestige of the committees that they are seen to stem from the highest institutional authority. The same recognition will be critical to the success of any similar committees which may be developed in Britain.

We can profit from the problems which have occurred in Sweden by avoiding some of the pitfalls. The anti-vivisection movement in Britain is proportionally smaller than its Swedish counterpart. The Nordic Society Against Painful Experiments on Animals (Nordiska Samfundet mot Plågsamma Djurförsök, NSPD) has a membership of 38,000 in a country with a total population of only 8.5 million. Furthermore, so evenly divided is the country politically that 70,000 votes could change the government. In such a situation, any sizeable pressure group can exert considerable political influence and this power is used astutely by NSPD. To deny representation of minority, extremist groups opposed to animal experiments on ethical committees in Britain would not be thought tendentious. Here convinced opponents of animal research will not be favourably impressed by the introduction of research review procedures. Certainly for the law-breakers, the situation has gone beyond the stage at which participation in this sort of constructive dialogue is possible.

In Sweden and America there is still opportunity for discussion and compromise between groups of all shades of opinion. Once this ground is lost, it is unlikely to be regained — which is why attempts to exclude Swedish anti-vivisectionists from the ethical committees may have retrograde effects.

Several factors seem to favour the introduction of local ethical committees to Britain and, if forthcoming legislation follows the recommendations of the 1983 Government White Paper, *Scientific Procedures on Living Animals* (HMSO, cmnd 8883), this will strengthen the case for their establishment, in defining a role for them in careful scrutiny of applications for project licences before submission to the Home Office.

We have available through the Home Office Inspectorate, an excellent means of supervising institute-based ethical committees and ensuring a desirable measure of inter-institutional standardization. By close liaison with the committees, inspectors could exert their own influence more effectively in the regions. Undoubtedly, the collaboration and support of the Inspectorate will be vital to the successful functioning of the committees.

Major animal welfare groups in Britain favour the concept of local ethical committees and can be relied upon to participate in any initiatives to establish these bodies — providing that they are more than window dressing for research institutions.

Perhaps an Uppsala-type experiment is necessary here before British scientists will be persuaded of the value of the animal research review process in the context of University activities. This will be considered more fully at a meeting being convened in the University of Liverpool on 1st and 2nd October in response to a demand from scientists for improvements and alternatives to animal experimentation.

Scientists will groan at the prospect of 'yet another committee', but if the protestations of genuine concern for animal welfare which are frequently voiced by animal experimenters mean anything, then priority must be given to this kind of provision. ☐

David P. Britt was awarded a Churchill Trust Travelling Fellowship (1984) to study ethical monitoring of animal experiments in North America and Sweden. He is at the Department of Veterinary Parasitology, Liverpool School of Tropical Medicine, Pembroke Place, Liverpool L3 5QA, UK.

Thunder and electric storms

A neat measurement of the stratospheric electrostatic fields throws light on the link between solar activity and terrestrial climate.

CAREFUL readers of the scientific literature are forgivably suspicious of articles that refer to the very distant past. The sceptical will ask whether the authors of such an article have sinister motives for ignoring recent work, and will probably dismiss the possibility that they have managed to resuscitate an important problem whose trail runs cold before, say, 1980. So what is to be made of the contribution now published by R.H. Holzworth and T. Onsager of the University of Washington (Seattle) and P. Kintner and S. Powell of Cornell University to the problem of atmospheric electrostatic fields? Their paper (*Phys.Rev.Lett.* **53**, 1398; 1984) manages one reference to a regular paper (by Holzworth) after 1980, but is mostly spattered with references dating from the 1920s and earlier.

Holzworth *et al.* have nevertheless managed to break new ground, and in a stimulating fashion. What they have done is to equip two balloons so as to measure the electrostatic field in the Earth's atmosphere at an altitude of 26 km. The balloons were released from New Zealand in March last year, and allowed to drift for two weeks eastwards across the Pacific at a latitude of 45°S. The lateral separation between the balloons was never less than 750 km. The objective was to compare the electric field strength at two such widely separate locations. The conclusion that the two records are very similar, but that fluctuations of field strength from day to day are much greater than expected, have an important bearing on the understanding of atmospheric electricity.

One of the obvious early references in Holzworth *et al.* is to C.T.R. Wilson, whose design of the closed chambers that became the workhorses of early cosmic-ray measurements was originally part of an investigation of atmospheric electricity. What Wilson knew was simple — that thunderstorms consistently carry positive electric current upwards in the atmosphere and that near the surface of the Earth, the electric field strength (the gradient of electric potential), while variable, can amount to several hundred volts per metre. Wilson had the wit to recognize that the cumulative effect of thunderstorms must be to some degree offset by a less spectacular but continuous downward electric current, for the electrical potential between the surface of the Earth (negatively charged) and a presumed upper conducting layer (the ionosphere) cannot increase indefinitely.

But how can the atmosphere conduct electricity, even at the low rate suggested by the observations? Wilson was the first to show that the production of ions by cosmic rays is the essential mechanism for rendering the bulk of the atmosphere conducting. The potential difference between the surface of the Earth and the ionosphere is typically no more than some tens of thousands of volts — the large potential gradient near the surface quickly trails off with increasing altitude as cosmic-ray ionization increases the conductivity of the atmosphere — at 26 km Holzworth *et al.* measure fields of less than 1 V m^{-1}.

The immediate significance of the new balloon measurements is that they have demonstrated a technique for measuring electrostatic fields beneath the ionosphere that is bound to become established if sparsely used. From this first batch of data, the conductivity at 26 km seems virtually constant for days on end, while the electrostatic fields measured by the two balloons, even when separated by up to 3,000 km, are identical to within 10 per cent for most of the time (perhaps 70 per cent of the 16 days of common observation). That is understandable if, indeed, the field at 26 km can be likened to the electrostatic field between two parallel conducting plates, one the ionosphere and the other the ocean surface.

For then, given the high conductivity of the upper and lower surfaces, the relaxation of the distribution of charge must be rapid. The local effects of thunderstorms carrying positive charge into the stratosphere would be quickly dissipated. Holzworth *et al.* point out that there nevertheless seems to be a daily variation of field strength at 26 km, at least when 10-minute records for consecutive days are averaged together, with a possibly shallow maximum of field strength at 20h Universal Time. The records, however, show no drift in the timing of the diurnal variation with the eastward passage of the two balloons across the Pacific, which provisionally gives the lie to theories that the global pattern of the vertical electrostatic field is fixed in relation to the position of the land masses on the surface of the Earth.

The chief interest of these data, according to their authors, is the enormous variation in the pattern of the vertical electrostatic fields measured by each balloon on different days. Field strengths are generally less at local morning than after noon, but otherwise the variability is so great that one day's record is unrecognizably different from the next's. The inference, which is important, is that there must be substantial fluctuations (perhaps by a factor of two) in the global vertical current in the atmosphere, and on time-scales of the order of 10 minutes, perhaps themselves the consequences of fluctuations of thunderstorm activity near the surface of the Earth.

While Holzworth (among others) has previously been responsible for vertical field measurements at altitudes up to 30 km, the twin balloon measurement seems to be the first of its kind. Evidently the conclusion that there are large short-term fluctuations of the global electrostatic field could not have been sustained by measurement with a single balloon (for local thunderstorms might always have been responsible). One obvious benefit that lies ahead is a more detailed correlation of the global field fluctuation with observed thunderstorm activity (presumably anywhere in the world). The point is obviously important because, while there seems little dispute about the correlation between thunderstorm activity and the strength of the electric field, the degree to which the former may be excited by the latter, involving as it does the non-linear dynamics of condensation in cumulus clouds, remains to be settled.

So does the possibility that the electrostatic field beneath the ionosphere may provide a physical link between sunspot activity and terrestrial climate. Ralph Markson has argued that solar activity, by affecting the cosmic-ray flux and thus the conductivity of the atmosphere, might influence the occurrence of thunderstorms (*Nature* **273**, 103; 1978), but by a mechanism which has been disputed (L.C. Hale, *Nature* **278**, 373; 1979) and which again hangs on the degree to which electric fields and thunderstorms are mutually stimulating.

Unfortunately, given the short-term global fluctuations of the vertical field, it is by no means clear how quickly careful monitoring of the electrostatic field by an *in situ* measurement will be feasible, and how quickly that will yield direct evidence bearing on the question whether solar activity and terrestrial weather are in any way linked by atmospheric electric fields. At least another sunspot cycle will go by before matters are cleared up.

John Maddox

Cosmology

Cosmologists in the dark

from Joseph Silk

IN their continuing quest to unravel the true nature of the Universe, cosmologists are beginning to pursue a most bizarre trail. Never mind that the Universe contains more mysteries than a whole galaxy of astronomers could ever unravel. Now we are learning that all the clues may be heralding a false dawn. What we see may have little to do with the true distribution of matter in the Universe. If galaxies formed only in specially-selected regions, then much of our painstakingly-acquired knowledge of the large-scale structure of the Universe, based on decades of observations with the largest telescopes available, may as well be discarded.

Could the Universe really be fooling us so effectively? The search for the holy grail of elementary particle physics, an ultimate theory of the unification of the fundamental forces of nature, has provided a persuasive argument. One of the successful outcomes of this approach has been the development of grand unification theories (GUTs) which incorporate the electromagnetic and nuclear (weak and strong) forces. Many GUTs exist, and some have a property of profound cosmological importance. There is likely to be a phase transition, associated with the spontaneous breaking of symmetry between strong and electroweak forces, in which sufficient entropy is liberated to trigger an epoch of exponential expansion. This inflation of the Universe can explain several outstanding cosmological conundrums, including the isotropy of the Universe and the origin of the fluctuations from which galaxies formed. One of its most remarkable predictions, however, is that the Universe should be, almost precisely, flat. If spatial curvature is negligible, the Universe will expand at a rate that barely overcomes its self-gravitational attraction. It will continue to expand, slowly decelerating, into the remote future.

In such a situation, simple application of Einstein's or even Newton's theory of gravity, if suitably generalized, to the expanding Universe leads one to infer a critical density of matter that our observed Universe must contain. This is equal to $3H_0^2/8\pi G$, where G is Newton's constant of gravity and H_0 is Hubble's constant for the linear expansion of the Universe, and amounts, very roughly, to an average density of about three atoms per cubic metre.

To compare what we actually see with this prediction, it is convenient to define the cosmological density parameter Ω to be the ratio of the actual density to its critical value, above which the Universe would eventually recollapse. Inflation predicts that $\Omega=1$ to within 1 part in 10^4. However, astronomers are almost unanimous in their assertion that the density of all observed matter amounts to $\Omega \approx 0.1$, with a factor of two or so uncertainty. The loophole for reconciling the observed Universe with the inflationary theory is that a component, even a dominant one, of the mass density that is uniform over the scale of galaxy clusters or superclusters would be very difficult to detect. Certainly, such a smooth backdrop has no direct influence on the dynamics of galaxies or those of galaxy clusters, which provide the principal means for determining Ω.

The evolution of the observed large-scale structure does depend very sensitively, however, on the distribution of an underlying dark component of matter. Gravitational instability, by which small density fluctuations in the early Universe have amplified into galaxies and galaxy clusters, would have been quenched had the dominant mass distribution always been, for example, very hot and consequently very uniform. On the other hand, if astronomers' measurements of $\Omega \approx 0.1$ are taken literally, one encounters a severe problem in understanding the extreme isotropy of the cosmic microwave background radiation. Recently reported by Juan Uson and David Wilkinson of Princeton University to be isotropic to 3 parts in 10^5 on an angular scale of 4.5 arc min, the background radiation should sample the seed fluctuations in the matter distribution at the epoch when the radiation was last being scattered. Lowering Ω reduces the effectiveness of gravity in amplifying these fluctuations, and to obtain the observed structures, one would infer for the most plausible models correspondingly larger ripples in the microwave background than are seen. With $\Omega = 1$, this problem need not arise.

A workshop devoted to increasing our understanding of the evolution of the large-scale structure of the Universe, and lasting eight months, has just ended at the Institute for Theoretical Physics in Santa Barbara, California. One of the most significant outcomes was a scheme for reconciling the dynamic measurements of Ω with a dense universe. The idea, developed most fully by J. Bardeen (University of Washington) and N. Kaiser (University of California, Berkeley), is that galaxy formation occurs only in a biased subset of the real Universe, at points where the critical density is particularly high. Consider a random field of density fluctuations (a three-dimensional analogue of the pattern of waves on the ocean surface) with power on both large and small scales. Suppose that the bright galaxies form only at the peaks of the density fluctuations. It turns out that the large-scale structure of the galaxy distribution can be much more pronounced than that of the underlying distribution. One way to visualize this is to imagine filtering noise with a low bandpass filter: the surviving intensity peaks tend to be more strongly correlated than the unfiltered distribution. A similar mechanism has been applied by Kaiser to explain the anomalously large clustering of rich clusters of galaxies.

A precise physical mechanism for producing such a bias has not so far been worked out. It is likely to involve feedback of energy by the first galaxies to form. Since the largest peaks on any given scale collapse first, one could readily imagine that some form of negative feedback, suppressing later formation of galaxies, might lead to a plausible biasing mechanism. A scheme of biased galaxy formation resolves many of the outstanding problems of the large-scale structure of the Universe. The weakly correlated dark matter leads to predictions of low galaxy peculiar velocities, in accord with astronomical measurements, and the spatial correlations predicted for the galaxies resemble what is observed.

As for galaxies, galaxy groups and clusters, the presence of gravitationally dominant dark matter within their luminous confines seems to be an observational fact. A second theme to emerge from the Santa Barbara workshop and one that is reviewed on page 517 of this issue by Blumenthal *et al.* is that cold dark matter gives rather a good fit to the prescription for our Universe. This dark matter, which consists of hypothesized weakly-interacting elementary particles such as photinos or axions, was sufficiently cold in the early Universe that fluctuations developed by gravitational instability over a wide range of scales, down to and even below that of a typical galaxy. The massive neutrino is the prototype of a species of weakly-interacting particles that would have been sufficiently hot, when freely streaming at the speed of light, to have erased all substructure on scales below those of great galaxy clusters. A hot dark matter scenario for galaxy formation has several unpalatable features, most of which arise from the constraint imposed by the near uniformity of the Universe on large scales. This model guarantees that the first scales to have undergone collapse and allowed galaxy formation to occur could only have done so at what seems to be an unacceptably recent epoch. Cold particle models, on the other hand, undergo hierarchical clustering at a relatively early stage, small scales condensing first, followed by successively larger-mass scales.

The cold particle-dominated universe appears to provide a satisfactory understanding of the distribution of dark matter on scales from those of dwarf galaxies to those of the great clusters of galaxies. Combined with a biasing mechanism, it reconciles the inflationary prediction of a universe at critical density with the astronomers' Universe. Even the distribution of fluctuations predicted by the inflationary theory is, according to Blumenthal *et al.*, reflected in the characteristic distribution of galaxy masses and densities. What remains to be shown is whether the giant voids in the galaxy distribution, such as that in Bootes, and the enormous aggregates of galaxies, such as that in the Serpens-Virgo region some fifty million megaparsecs across, can be reconciled with such a theory. One of the most tantalizing aspects of the currently moribund idea of a universe dominated by massive neutrinos was that it naturally predicted the presence of large filaments and sheets of galaxies, separated by huge voids. It may not be so easy for a cold particle-dominated universe to meet the same challenge. ☐

Astrophysics

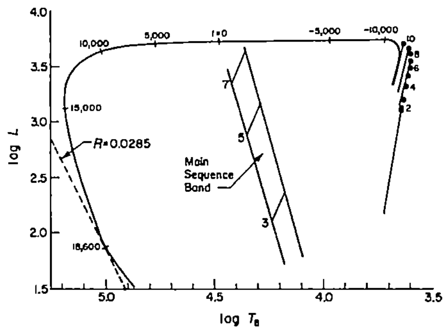
Oscillations of degenerate stars

from Arthur N. Cox

RECENTLY there has been renewed interest in the oscillations of degenerate dwarf stars. Very-low-luminosity variations were first seen in the white dwarf HL Tau-76 by Landolt some 20 years ago[1], and since then, luminosity variations with periods ranging from hundreds to thousands of seconds have been detected in many other white dwarfs. The past few months have seen several predictions confirmed by new observational discoveries, and the scope of our research and understanding of degenerate star oscillations greatly expanded.

The stars that have stimulated the interest are very small, with radii ranging from 1 - 10 per cent of the radius of our Sun, only slightly bigger than that of the Earth, and a probable mass of 0.6 solar masses (M_0). Their mean density is therefore very high, about 10^6 g cm^{-3}, implying the presence of electron degenerate matter throughout most of their mass. Because degenerate matter conducts heat easily, white dwarf stars have core temperatures as low as 10^7 K or less and, thus, are much cooler than any other stars except the lower-mass very-faint red dwarfs. White dwarfs produce no nuclear energy because any potential fuels, such as hydrogen and helium, are found only in their cool surface layers, so their luminosity is low. Because of their very small size and low luminosity (less than 1 per cent of that of our Sun) it has taken billions of years for the surfaces of these stars to cool to their current temperatures, typically 10,000 K.

Stellar evolution theory predicts that stars with masses of up to at least 6 *M*. evolve to become white dwarfs (see the figure). As these stars burn their initially copious supply of hydrogen to helium and the helium to carbon, oxygen and neon in a growing electron-degenerate core, they expand and increase in luminosity, to become red giants or supergiants. When they have reached a radius of perhaps 100 or more solar radii, they lose mass, sometimes to produce planetary nebula shells, by shedding all but the CNONe core resulting from the hydrogen and helium burning. The remaining core has a surface temperature typically of 150,000 K and a luminosity of 10,000 solar luminosities. Because the stars have lost the layers in which nuclear processes take place, they can no longer produce any new energy to sustain their luminosity and they rapidly (within no more than 10,000 - 100,000 years) become very small and hot. Finally, slow cooling turns these hot dwarfs into faint white dwarfs after millions of years.



Hertzsprung–Russell diagram where luminosity is plotted versus the surface temperature, showing the evolution of a 0.6 *M*. star (adapted from ref.10). The initial increasing luminosity tracks for stars of 3, 5, and 7 *M*. are indicated as the main sequence band. The final stages of nuclear burning of the 0.6 *M*. star result in 10 helium shell flashes where the luminosity is greatly increased for durations of hundreds of years. These are marked at the very coolest surface temperatures where the mean emitted luminosity is still increasing with time. Zero time is arbitrarily set at the moment when the surface temperature increases to 30,000 K. The track represents hot dwarfs (upper left), turning as they slowly cool to become very faint white dwarfs (below the bottom of the figure). The minimum radius of the hot dwarfs is 0.0285 solar radius, and later this radius decreases as the conventional white dwarf is formed.

Many hot luminous stars have been discovered and very recently five of them have been found to show 5 - 30 minute period variations in their luminosity of a few per cent (ref.2 and H.E. Bond & A.D. Grauer, personal communication). These stars constitute a new class of variable, called PG variables, after the first studied PG1159-035 which is perhaps the hottest variable star in the sky. Oscillations of these stars are thought to result from the periodic ionization of carbon and oxygen in their surface layers. While they oscillate, the stars deviate from their spherical shape, hence their classification as nonradial pulsators. Last year, Starrfield *et al.* predicted that the stars would pulsate in nonradial g modes only if about half of the mass of their outer pulsation-driving layers was oxygen, and helium comprised only a small fraction[3]. Now, a large oxygen abundance has been verified spectroscopically[4]. Observations of helium at the stars' surfaces, however, indicate incomplete loss of this fuel. If there is enough helium, another shell flash may occur during the stars' evolution. Further studies of the longer-period K1-16 planetary nebula central star listed in the Kohoutek catalogue are underway to see what pulsations would be predicted at earlier and cooler stages of this luminous stellar evolution.

The same cyclical ionization of hydrogen and helium that drives the pulsations of Cepheids also causes the much cooler and older ZZ Ceti stars, the classical white dwarfs, to pulsate. The κ and γ effects drive motions by both blocking and hiding the radiative luminosity at key compressed phases of the pulsation cycle. At subsequent phases, the radiation is allowed to flow more strongly so that the oscillations are driven as the stars re-expand.

A further intriguing class of variable stars is the DB white dwarfs. These stars have helium-rich atmospheres and, probably, helium-rich pulsation-driving layers with temperatures of 100,000 K or more. They do not have hydrogen ionization driving, but they do have the driving mechanisms from the ionization of helium. Winget *et al.* predicted that these helium stars should pulsate in nonradial modes[5], and recently this has been confirmed in three cases (ref.6 and H.E. Bond & A.D. Grauer, personal communication).

What does the future hold in store? Several groups[7-9] have predicted that radial pulsations in high overtones should occur in white dwarfs. Perhaps the next observational discovery will be that these approximately 1-second oscillations also exist.

Vaccines

In search of novel immunogens

from Peter Newmark

To judge by a recent meeting*, empiricism and tradition still offer at least as much to the production of new vaccines as rationalism and peptides. But the possibility of basing new vaccines on synthetic peptides that correspond to immunogenic parts of a pathogen's structure is acting as a great stimulus to immunochemists and their allies.

The initial problem with the peptide approach to vaccines is to identify immunogenic peptides. Were it possible to do that from no more than the amino acid sequence of a protein, life would be easy. But, although it is possible to predict crudely which segments of a sequence will form the surface of a folded protein, and although such segments, in peptide form, are likely to be antigens, they will not necessarily be immunogenic, in the sense of evoking a sufficient immune response to neutralise the pathogen. Moreover, it is inevitable that many, and probably most, immunogenic sites on a protein are not composed of contiguous amino acids but rather of amino acids that are juxtaposed by protein folding and so cannot readily be mimicked by a synthetic peptide.

For the most part, immunogenic peptides have been identified by screening candidates with monocloncal antibodies that neutralize the relevant pathogen *in vitro*. A promising new technique, requiring neither prior peptide synthesis nor sequence information was described by J. Nunberg (Cetus Corporation). The cloned gene of an immunogenic protein of a pathogen (feline leukaemia virus in the first case) is cut into random short fragments by DNase 1. The fragments are cloned into Lambda phage 'Charon 1b' in such a way that they are expressed. Phage colonies are screened with a monoclonal antibody that neutralises the pathogen. Those that react with the antibody must be expressing an antigenic peptide from an inserted gene fragment which is then sequenced (see *Proc. natl. Acad. Sci. U.S.A.* **81**, 3675; 1984). In that way, Nunberg reported, it had been possible to identify a 14-amino acid immunogen of the envelope protein of feline leukaemia virus. The corresponding synthetic peptide was able to compete with the virus for antibody. Moreover, when attached to a carrier and used to vaccinate guinea pigs, the peptide elicited a partial immunogenic response which was markedly enhanced by subsequent administration of a low dose of killed virus. An efficacy trial of this approach to a vaccine against feline leukaemia virus in cats is now being set up.

E. A. Emini (Merck Sharp and Dohme) reported a roundabout, but revealing, identification of immunogenic sites on the hepatitis A virus, a relative of poliovirus. Starting from the fact that antibodies against hepatitis A virus demonstrate some cross-reactivity with peptides representing major immunogenic sites on the VP1 protein of poliovirus type 1, and taking into account the observation that these peptides could prime animals to respond to a sub-immunogenic inoculum of hepatitis A virus, Emini expected to find that certain sequences within the VP1 of hepatitis A virus closely matched those of the poliovirus peptides. But the relevant cDNA sequences (J. Hughes, Merck Sharp and Dohme; B. Baroudy, National Institutes of Health, Bethesda) revealed no such match. Nor was there a concordance in the calculated secondary structures of the two VP1s. Only when a comparative analysis of the predicted surface features of the two proteins was made, was a striking similarity observed. Based on this comparison of 'shape', Emini *et al.* have synthesized a hepatitis A virus peptide, monoclonal antibodies against which have virus neutralising activity, mostly cross-react with the virus and in some cases compete with antibodies in the sera of humans infected with hepatitis A virus. These data underline the importance of the 'shape' of the surface of immunogenic proteins and explain why much effort is being invested into an understanding of 'shape' and its determinants.

Another way to investigate the relationship between structure and immunogenicity is to document any differences in sequence between a virus that can be neutralised by a monoclonal antibody and any genetic variants that resist neutralization. The expectation would be that resistance is the result of mutations within the sequences that encode antibody-binding regions of the protein. However, D. Diamond (State University of New York, Stony Brook) reported that expectations were confounded in the case of poliovirus type 1. Two regions within its VP1 protein have been identified as antibody binding sites but virus variants that resist neutralization have amino acid changes elsewhere on VP1 or even on VP2 or VP3 proteins. Presumably, within the virus proper, the mutated amino acids are either juxtaposed to the identified antibody binding sites or affect conformation at a distance.

Also intriguing were the sequence comparisons of an attenuated strain of poliovirus type 3 (used in the Sabin-type vaccine), its parent and some strains that are revertant in terms of their neurovirulence (J. Almond, Leicester University). The attenuated strain had ten base changes from its parent, only three of which give rise to amino acid changes. Contrary to expectation, none of these three is consistently of the parental type in the revertants; the only consistent base reversion is in a non-coding position. By recovering the poliovirus from sequential nappies of a vaccinated child the same base reversion has been documented to occur within 36 h of vaccination with the attenuated strain. Clearly the reversion is strongly selected for — but why?

A whole session of the meeting was devoted to the possible resurrection of vaccination with vaccinia virus, using it to carry and express a wide variety of immunogens. This possibility was recently put in its proper perspective in these columns by J. Beale (6 September p.12), and F. Fenner (John Curtin School of Medical Research, Canberra) provided more perspective at the meeting. Both commented that the known, though very infrequent, complications of smallpox vaccination could be a barrier to the return of vaccinia inoculation. But R. Buller (National Institutes of Health, Bethesda) described some parameters by which the virulence of vaccinia virus can be reduced if the thymidine kinase gene of the virus is used as the target for insertion of new immunogen genes.

In a novel application of the vaccina approach H. Koprowski (Wistar Institute) reported that vaccinia virus recombinants containing the gene for the immunogenic glycoprotein of rabies virus are able to protect experimental animals against an intracerebral challenge by the virus. K. Cremer (National Institutes of Health, Bethesda) reported that intradermal inoculation of mice with vaccinia virus carrying the gene for glycoprotein D of herpes simplex virus type 1 provided protection against both type 1 and type 2 virus and also inhibited latent ganglionic infection by type 1 virus. And E. Paoletti (New York State Department of Health, Albany) described inoculation experiments using a vaccinia virus in which the genes for immunogens of hepatitis B, herpes simplex and influenza viruses had been inserted at different sites; each provoked an antibody response, demonstrating the potential of vaccinia virus as a polyvalent vaccine.

Another approach to new polyvalent vaccines was described by P. Valenzuela (Chiron Research Laboratories). The idea is to recombine the gene of a second immunogen with that of hepatitis B surface antigen (HBsAg) so that the second immunogen is assembled into, and presented on, the HBsAg particles that engineered yeast and mammalian cells produce. As an initial step in that direction, the gene for glycoprotein D of herpes simplex virus has been recombined with that of HBsAg and a lysate of yeast containing the recombinant has been shown to react with antibodies against both proteins.

Ironically perhaps, the recombinant was made by inserting the herpes gene into the

---

*'Modern Approaches to Vaccines', Cold Spring Harbor, 12–16 September, arranged by R. Chanock and R. Lerner. The proceedings will be published in January 1985.

'pre-S' sequence that precedes the 'S' sequence of HBsAg and encodes a 55 amino acid extension which is poorly represented in serum HBsAg particles and is not found in yeast HBsAg particles because only the S gene has been engineered into yeast. The irony is that the pre-S encoded extension may be too important to be ignored or disrupted according to S. Kent (California Institute of Technology). Data he presented suggest that the pre-S extension is more immunogenic than the S gene product; that it should be included in hepatitis B vaccines; that a synthetic peptide corresponding to the amino terminus of pre-S might itself be the basis of a vaccine; and that antibodies against the peptide will find diagnostic uses. Note, however, that serum and yeast HBsAg particles have been shown to protect chimpanzees against hepatitis B virus challenge, as has vaccinia virus carrying the S gene (see J. Beale *op.cit.*)

Space forbids mention of many other diseases for which a modern (sometimes not so modern) approach to a vaccine was reported. It should , however, be recorded that a session and a half was devoted to the prospects of a malaria vaccine and to the repetitive sequences within most of the potential malaria immunogens; the bulk of what was reported has recently been discussed in these columns (27 September, p.300 and 16 August, p.541). ☐

Biological aerodynamics

Flight of fancy planned for the largest pterosaur

from Kevin Padian

AT one time, pterosaurs, the 'flying reptiles' of the Mesozoic era, seemed relatively simple to understand. They were considered to be bat-like inferior prototypes of birds, incapable of flapping flight or of efficient locomotion on land, no more than an early experiment in vertebrate flight. The giant *Pteranodon*, with its 7 m wingspan, seemed to be at the upper limit of any flying creature's size. Their replacement by the 'real masters' of the air, the birds and the bats, could easily be explained by a factor as trivial as a change in the average wind speed at the end of the Cretaceous (Bramwell, G.R. & Whitfield, C.D. *Phil. Trans. R. Soc.* B**267**, 503; 1974).

Recent work has called for a re-evaluation of these bizarre animals; none more so than the discovery of the giant *Quetzalcoatlus northropi* (Lawson, D.A. *Science* **187**, 947; 1975) which, with a wingspan currently estimated at 11 m, was 50 per cent larger than *Pteranodon.* This remarkable beast was responsible for a recent gathering* of over 30 engineers, aerodynamicists, palaeontologists and inventors in Pasadena, California, to discuss the possibility of building an accurate radio-controlled flying model of the creature. The purpose of such a venture would be not only to challenge the potential of ornithopter technology, but also to use the problems posed to the aerodynamicist to illuminate the biological limitations of the largest animal ever known to fly.

Before any accurate flying model of a pterosaur can be built, it will be necessary to have as complete a picture of these animals as possible. Much of the conference was therefore devoted to reviewing the most recent findings.

We now know that pterosaurs' wings were attached, not bat-like to the feet, but to the pelvis, to give a much more attenuate planform (Wellnhofer, P. *Abh. bayer. Akad. Wiss.* **141**, 1; 1979); the resultant wing loading resembles closely that of modern fliers (Padian, K. *Discovery* **14**, 20; 1979). All pterosaurs, except the largest ones (like the largest birds), were active fliers; their wings were fully folded when they walked on the ground, which they did bipedally: their forelimbs are functionally homologous to those of their closest relatives, the dinosaurs and birds, not to those of the bats (Padian, K. *Paleobiology* **9**, 218; 1983).

Recent models have treated the wing membrane as if it billowed with no internal structure, and ignored the probability that most pterosaurs having a wingspan of less than 3m seldom glided or soared, but flapped continually. Moreover, finely preserved specimens of *Rhamphorhynchus*, from the Late Jurassic of West Germany, show a series of fine, intercalated and stiffened striae permeating the entire wing membrane (Wellnhofer, *op. cit.*). This arrangement resembles the structural elements in the wings of birds (feather shafts) and bats (fingers), and suggests a role in maintaining the shape of the wing. The striae may have helped to determine the camber of the wing, although the details of their muscular control, including the extent to which the wing may have been collapsed without losing its aerodynamic integrity in flight, are not known.

Some idea must also be had of the dimensions and mobility of the animal to be modelled. This is complicated by the bimodal distribution of *Quetzalcoatlus* specimens. Thus there are around 20 partially-preserved 'small' individuals, with wingspans of about 5.5 m. Taken collectively, they provide a complete three-dimensional picture of nearly every wing element (Langston, W. *Scient. Am.* **244**, 122; 1981). Then there is the giant specimen, known initially from its tree-like 50 cm long humerus. Each of its incomplete skeletal elements is approximately twice the length of its homologue in the 'small' form, although its shape is much more robust. Doubling the dimensions of the smaller form is not adequate for some parts of the body, including the torso, of which there are very few remains. Body length can be extrapolated from the few dorsal vertebrae preserved, but body weight is more difficult to determine and estimates range from 50 to 100 kg; until a scale replica of the animal can be built from preserved material, a weight of about 65 kg has been provisionally accepted. The wing area must depend on the length of the body, and seems to have been about 8.13 m^2; this yields a wing loading of approximately 0.8 g cm^{-2}. *Quetzalcoatlus* had an aspect ratio of about 15 which, although high by the standards of natural fliers, is significantly lower than that of *Pteranodon* and other smaller seagoing pterosaurs. No living or man-made flier is an exact analogy for pterosaurs, although ultralight sailcraft may serve the purpose (McMasters, J. *NASA Conf. Pap.* **2085** (II); 1979).

The practical problems of replicating the flight of such an animal in a radio-controlled soarer-ornithopter are just beginning to be addressed. The first is that *Quetzalcoatlus*, like all pterodactyloid pterosaurs, had no tail, so pitch control will be complicated. Its neck and head were, by contrast, remarkably long, each about 2 m, while its entire torso was much shorter and its legs did not trail far behind the body. How far the neck could have been retracted or bent, if at all, is an important problem for paleontologists and has implications for engineers for calculating the centre of mass. The long neck and head form a powerful lateral moment arm, but also create a large amount of inherent instability; some sort of balancing mechanism up front will be necessary to control this. There are also logistic problems in trying to construct joints that can, for example, trim the wings and adjust pitch, while also supplying power for climbing flight.

The aim of the project is to launch the model from the Air and Space Museum of the Smithsonian Institution, from where it will fly across the Mall, climbing under its own power, circle the Washington Monument and return. To add realism, it has been suggested the model might pause in its flight, swoop down to snatch a small child from the crowd, carry it aloft, and consume it. For the present, mercifully, that objective seems to be beyond the technological capabilities of the field of Robotics. ☐

Kevin Padian is Assistant Professor of Paleontology at the University of California, Berkeley, California 94720.

Geophysics

Continental interior in view

from Roger N. Anderson

ANOTHER frontier of geological exploration may at last be yielding to curiosity and advancing technology. After the great geological expeditions to the Moon, and dramatic discoveries of the ocean floor made over the last twenty years, the attention of a surprisingly large number of geologists worldwide is turning back to the original geological problem: the internal workings of the continents.

We know very little about how the continents form and deform. What we infer comes from remote-sensing with the use of classical geophysical and geochemical techniques such as seismology, gravity, petrology and minerology. But the sources of these observations are always at the surface. Although we can build elaborate models of the continental interiors, we shall never be able to verify these concepts without looking inside the continents. Experiments to this end are now being planned in several countries. The tool used to sample the inside of the Earth is the drillbit.

A remarkable coincidence of planning means that several countries will begin programmes of deep crustal drilling in 1986. German plans, outlined by E. Seibold at a conference* earlier this year, are to drill to at least 7 km through the Hycenian overthrust in the Black Forest. The aim is to understand how huge masses of rock could have slid several hundred kilometres over only slight slopes in the geological past. High pore pressures are suspected essentially to have floated these masses over other rock, but not a single measurement of pore pressure is yet available from such a shear zone. Scientists in Sweden, the United States, France, Austria and Japan are also planning to begin deep continental drilling in 1986.

Why are so many national programmes focusing on the drillbit at about the same time? Technology is probably the major driving factor. The international oil industry has developed in the drillbit a remarkable technology ideally suited for geological purposes as well as for hydrocarbon exploration. F. Schuh (Atlantic Richfield), for example, presented the conference with an entirely feasible design for a 50,000 foot well into crystalline rock. Several speakers (including G. Olhoeft and B. Dennis, US Geological Survey; P. Lysne, Sandia; M. Mathews, Los Alamos) offered a staggering array of geophysical and geochemical measurements and *in situ* experiments that can now be accomplished in a deep hole. It is now possible to measure accurately the pore pressure, permeability, electrical and thermal conductivity, sonic, ultrasonic and seismic character of the wellbore as well as the exact chemical composition of the rock and pore fluids that are being drilled through.

It was not just these visions of technology that captured imaginations at the conference but also the accomplishments of continental drilling projects already well underway. Although not in attendance, the Russians dominated this phase of the meeting. They have been drilling deep into the continent for over 10 years, and at one hole on the Kola peninsula, they have made extraordinary discoveries. The current dogma holds that the deep crust is void of minerals and fluids because fractures, abundant at the surface, cannot remain open to fluid flow at great pressures. The Russians have found just the opposite: at 13 km depth, they encountered open fractures, mineralization and abundant evidence of fluid transport. They even discovered liquid sulphur, which is hydrolysed in the drilling mud to form sulphuric acid which eats away their drillbit.

The highlight of the conference was P. Robinson's (Dalhousie University) report of results from an international group, supported by Canada, the UK and US, that is drilling through the Troodos Ophiolite on Cyprus. Deep penetration of the pillow basalts and underlying sheeted dike complex, has shown that Troodos is made neither from ordinary sea floor, nor from back-arc basin sea floor as has long been thought, but is instead the inside of an island arc. Moreover, M. Salisbury (Scripps Institution of Oceanography), using technology supplied by the British company British Plaster Board, has conducted a complete suite of geophysical measurements inside the hole, or logs. This revealed that the internal plumbing of an island arc produces layered structures almost identical to the crustal layers of the ocean floor. Hence the mistaken origin of the complex.

By August 1984, this collaboration had drilled to within 180 m of the MOHO, the seismic discontinuity between the Earth's crust and mantle. The penetration of that barrier — originally the aim of the Deep Sea Drilling Project — now looks likely to be achieved first by the Troodos drilling project. We eagerly await information on what lies beneath it.

The conference ended with an air of great optimism. Participants had heard from Bob Luth (Sandia) of a greater than 1 m penetration of magma inside Kiluea Volcano, Hawaii, and from W. Elders (University of California, Riverside) that drilling was about to begin in the 350°C waters of the Salton Sea geothermal area. Our understanding of the Earth was revolutionized by plate tectonics, which arose from exploration of the ocean floor. The exploration of the interior of the continents promises to further that understanding by a similar degree. □

Roger N. Anderson is in the Lamont-Doherty Geological Observatory of Columbia University, Palisades, New York 10964.

Archaeology

Kin-groups in Megalithic burials

from C.J. Scarre

MEGALITHIC tombs are among the most impressive neolithic monuments of western Europe, and a principal source of information about social organization in that period. Communal burial was the prevalent rite and in cases in which a tomb has not suffered too severely from the attentions of nineteenth-century antiquarians or been destroyed by a landowner, the archaeologist can expect to find large quantities of human remains. Despite their evident potential, however, analyses of such bone assemblages all too often fail to go beyond estimating the number and stature of the individuals represented and commenting on any obvious traces of injury and disease. How much more information this material holds is vividly demonstrated by the recent work at La Chaussée-Tirancourt, where the study of osteological abnormalities has allowed a series of distinct burial populations to be identified which may correspond to the different kin-groups using the tomb.

La Chaussée-Trancourt lies a few kilometres west of Amiens and is a megalithic monument of the '*allée couverte*' type, with a burial chamber 9 m long and 2 m wide. By careful excavation over several years, Claude Masset and his team have recovered the remains of 356 individuals, 60 in layer V towards the bottom of the chamber and almost 300 in layer III higher up[1] (see figure). Within layer V, four separate 'zones' of burials were identified, while in layer III the human remains were concentrated in 'cases', which probably had originally been compartments or containers of wood or other organic material long since perished. At the end of its use the tomb was sealed by a substantial deposit of chalk and earth, on the surface of which fierce fires were lit, leaving a thick layer of ash. Curiously, the customary megalithic capstones are absent in this instance: the roofing of the chamber before the final

21-1-87 A. Eatle

burning must instead have been of wood or thatch. Objects associated with the burials and radiocarbon dates from the layer of ash suggest that the monument was used actively between the late third and early second millenia BC.

Recently, Masset[2], Amaya Rodriguez Hernandorena[3] and Pascal Sellier[4] have carried out detailed analyses of the human material recovered from the tomb, concentrating on four bones (tibia, femur, humerus and calvarium) and on some fifty discrete (that is, non-metric) characters that are probably genetically determined. In both of the principal burial layers, the distribution of the characters among different parts of the tomb chamber was found to be significantly non-random (see figure).

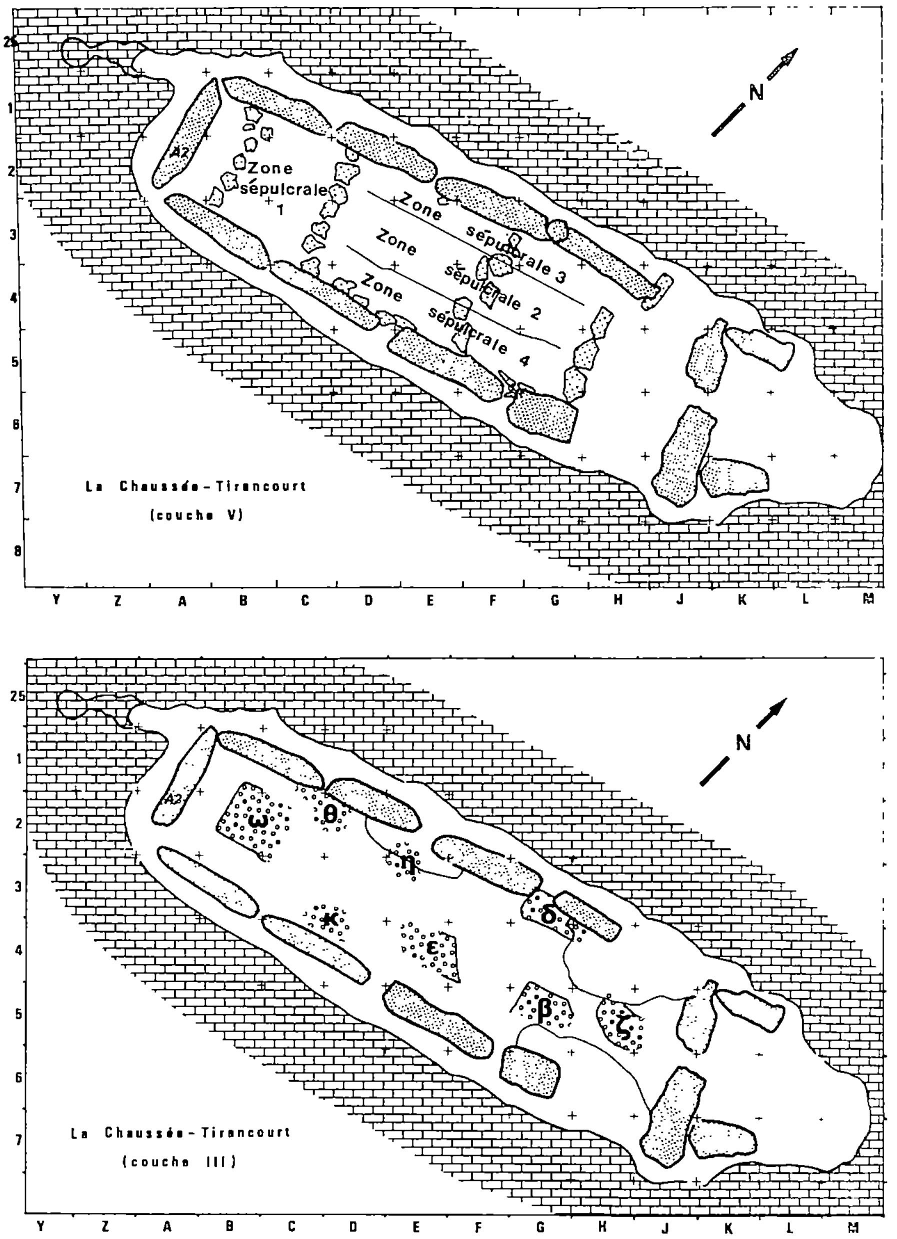
In layer V, the remains from zones 2 and 4 form a single group chacterized by a high incidence of incrustation of the humeral trochloea. Zone 1 is distinguished by the rarity of a third trochanter on the femur, a feature fairly common in the layer as a whole, and by an unusually high frequency of hypotrochanterian fossae. These and similar abnormalities allow the burials in layer V to be divided into three distinct populations: zones 1, 2 and 3/4.

Layer III shows a comparable, though somewhat more complex, patterning as the cases provide eight separate burial units. Case ω is distinguished by the frequency of an additional articular facet on the tibia. Cases ε, β and ζ share the absence of an olecranian perforation in females and the common presence of a hypotrochanterian fossa, but only case ε has a relatively high incidence of incrustation of the humeral trochlea.

The presence of the same abnormalities in the bone assemblages of layers III and V suggest that the populations of the two layers were probably related, though some characters are more common in one than in the other, and the individuals in layer III are on the whole less robust and closer to the norm than those in layer V.

A recent study argues that megalithic tombs of the *allée couverte* type in north eastern France served as community foci for populations living in scattered hamlets or farmsteads round about, the burial of members of the different households in the central tomb operating as a crucial mechanism of social integration[5]. At La Chaussée-Tirancourt, the concentration of individual abnormalities in the different zones and cases suggest that each of these units was reserved for a separate kin or household group. This reservation of particular parts of the chamber for specific kin-groups may have persisted throughout the life of the tomb, since, for instance, incrustation of the trochlea is a common feature of humeri from the south-central sector both in layer III and in layer V. The spatial arrangement of the burials of related individuals in the tomb therefore reflects the scatter of family or household groups in their small settlements.

The research on the bone material from La Chaussée-Tirancourt clearly demonstrates the potential use of genetically-dependent osteological abnormalities for improving our understanding of prehistoric burial practices. It is hoped that the excavation currently being conducted by Masset at Méréaucourt, another northern French *allée couverte*, will amplify the picture and throw further light on the social organization of the populations that used these monuments. ☐



The megalithic tomb of La Chaussée-Tirancourt, showing the arrangement of the burials of the two principal layers in 'zones' (layer, V, top) and in 'cases' (layer III, bottom). From ref. 2 and reproduced by permission of C. Masset.

---

100 years ago

PROF. Ira Remsen testified to the utility of valence. He remarked that there were two ways of teaching: one by giving all the principal theories first, and the other giving the facts and then the theories — which latter he considered the best method. He had come to the conclusion that valence should never be mentioned until all the important properties of a compound are known. In regard to its value to young students, he thought its use was dangerous until they fully understood its meaning. He believed that the value of valence had been magnified, and that it was better to study the reactions of compounds, and the methods for their synthesis, and the manner of breaking-up.

Mr A.H. Allen said that many formulae that showed the structure of compounds according to the valence of the elements do not give any idea of the true constitution of these compounds as ascertained from their properties.

Parkinson's disease

Clues to aetiology from a toxin

from Solomon H. Snyder

UNTIL recently Parkinson's disease was one of few neurological conditions whose pathophysiology was presumed to be 'solved'. Degeneration in the corpus striatum, which regulates motor activity, leads to rigidity, difficulty in moving, and tremors of the limbs. Hornykiewicz, in 1960, showed that the neurotransmitter dopamine is depleted from the corpus striatum of affected patterns[1] and Cotzias later developed a therapy based on orally administered L-DOPA, the amino acid precursor of dopamine[2]. At the same time, histochemical studies showed that the major dopamine pathway in the brain has cell bodies in the substantia nigra with axons ascending to terminate in the corpus striatum[3]. An animal model of Parkinson's disease soon followed: when injected into the vicinity of the substantia nigra, 6-hydroxydopamine, which is readily oxidized in cells to a toxic quinone, selectively accumulates through a pump-like mechanism exclusive to dopamine neurones with the result that the nigrostriatal dopamine pathway is destroyed.

This model, however, sheds no light on the aetiology of Parkinson's disease and may not even be adequate as a model of the human disease, since Parkinsonian brains show damage in areas other than the substantia nigra, including the noradrenaline-containing locus coeruleus. Several recent papers, two of them just published in *Nature*[4,5] show how a new animal model, based on the toxicity of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP), may overcome both shortcomings.

The toxin was originally implicated through a bizarre detective story. In the late 1970s a chemistry graduate student suddenly developed severe Parkinsonian symptoms, which were peculiar because of the patient's youth and the abrupt onset of the disease. The diagnosis was confirmed, following the patient's death from a drug overdose, when an autopsy revealed selective degeneration of the substantia nigra. Astute research scientists at the National Institutes of Mental Health in Bethesda learned that the patient had been synthesizing, for illicit sale, a close relative of the well-known opiate, meperidine. Chemical analysis of samples recovered from the patient's basement laboratory revealed contaminants, especially MPTP[6]. Subsequently, Californian investigators identified several patients with virtually identical clinical symptoms who had also taken preparations containing MPTP[7].

These cases have prompted speculation that MPTP or similar environmental toxins might 'cause' most cases of Parkinson's disease[8]. Direct ingestion may not be necessary: recently a 37-y-old chemist developed serious irreversible Parkinson's disease while using MPTP as a synthetic intermediate[9], but without ever ingesting it. Inhalation or skin contact may have sufficed to elicit the condition. Since MPTP itself is not toxic to cells, it is presumably converted to a more chemically reactive form. This fits the well-documented observation that cigarette smokers are less prone to Parkinson's disease than non-smokers[10,11], in the sense that carbon monoxide, which accumulates in the tissues of smokers, may detoxify active intermediates produced from MPTP and related agents. If Parkinson's disease is due to environmental toxins, one need not expect the sudden onset that follows MPTP ingestion, nor would chronic, lifelong exposure be required. Instead, initial damage to the substantia nigra, which might occur early in life, combined with the natural decrease with age of the dopamine-containing cells in the substantia nigra, could suffice to produce symptomatic Parkinsonism.

Several workers have used MPTP to develop an animal model of Parkinson's disease and have found species differences that have provided important clues to the mechanisms of toxicity. Unlike rats and guinea pigs[12-15], rhesus monkeys[12] and squirrel monkeys[16] given MPTP develop clinical Parkinsonian symptoms and show selective destruction of the substantia nigra. MPTP also produces irreversible depletion of striatal dopamine in mice[17-19].

MPTP can be oxidized by mitochondrial enzymes such as monoamine oxidase and possibly aldehyde dehydrogenase to 1-methyl-4-phenylpyridine (MPP^+), a charged pyridinium derivative[20], which is chemically reactive and toxic to tissues. It is detectable in the brain for prolonged periods after *in vivo* administration of MPTP [4]. An impressive link between the oxidation and neurotoxicity of MPTP has been reported by Heikkila and associates[5] who show that its neurotoxicity in mice can be prevented by pretreatment of the animals with monoamine oxidase-inhibiting drugs, which also block the conversion of MPTP to MPP^+.

But how does one explain the selective effect of MPTP on brain structures such as the substantia nigra and corpus striatum? Although MPP^+ is formed to a similar extent in all areas of the brain[12], species variations in recently identified receptor-like binding sites for MPTP may help provide an answer. MPTP binds with high affinity ($K_D = 2 \times 10^{-8}$M) to receptors in brains of numerous species. By autoradiographic techniques one can visualize MPTP receptors. In human brain they are most highly concentrated in the substantia nigra and corpus striatum[21] but we[21] and others[22] find substantially fewer receptors in the same regions of rat brain. Species variations in nigrostriatal receptor density thus may account for the lesser toxicity of MPTP in rats. Both human and rat brain have MPTP receptors in several other areas. One site of particularly high receptor density is the locus coeruleus. This localization fits well with the marked changes in noradrenaline metabolism that follow MPTP treatment of rats[13,14] and monkeys[12], with the pronounced changes in accumulation of 2-deoxyglucose by the locus coeruleus in MPTP-treated rat and guinea pig[23] and with the degeneration of the locus coeruleus in Parkinson's disease.

The most recent revelation in the MPTP story comes from Parsons and Thomas C. Rainbow (a leader in autoradiographic studies of neurotransmitter receptors, who met an accidental death on 6 September 1984). They compared by autoradiography the localizations of binding sites for ^{3}H-MPTP and for the monoamine oxidase inhibitor ^{3}H-pargyline[24], which selectively labels the type B isozyme of monoamine oxidase. Localizations of the two binding sites were virtually identical, indicating that the MPTP receptor may be the type B enzyme monoamine oxidase itself.

These findings not only reinforce the role of monoamine oxidase in MPTP actions, but also raise the intriguing possibility that the selective receptor binding sites that have been reported for diverse drugs might be enzymes rather than receptors for endogenous neurotransmitters. The very discrete localizations observed for monoamine oxidase suggest a more selective role for this enzyme in brain function than was previously suggested. ☐

Similarity between p15E of murine and feline leukaemia viruses and p21 of HTLV

SIR — Retroviral infections of a number of animal species are frequently associated with immunosuppression. The hydrophobic retroviral transmembrane protein p15E is highly conserved among type C and type D retroviruses[1]. This protein may contribute to the immunosuppression associated with retroviral infections since it inhibits *in vitro* lymphocyte transformation in man[2], cats[3] and mice[4] and increases tumour incidence in cats given feline sarcoma virus[5]. The mechanism for the inhibition of human lymphocyte transformation by p15E was shown to be due to suppression of interleukin-2 (IL-2) production[6]. We have demonstrated *in vitro* suppression of human monocyte function[6] and *in vivo* inhibition of murine macrophage accumulation to inflammatory foci by p15E from murine leukaemia virus (MuLV)[7] or by tumour-associated proteins which are antigenically related to p15E[6,8].

Human T-cell leukaemia-lymphoma virus (HTLV) is the designation for a family of T-lymphotropic, exogenous type C retroviruses which have been isolated in a number of countries[9-13]. These viruses have been linked as aetiological agents to certain types of leukaemias and lymphomas and to the acquired immunodeficiency syndrome (AIDS)[14-16]. It has recently been reported that the polymerase gene products of HTLV, MuLV and avian Rous sarcoma virus are partially homologous in their amino acid sequence[17]. Since immunosuppression often accompanies the HTLV-associated T-cell malignancies and is characteristic of AIDS, we hypothesized that HTLV-viruses might have, in addition to their lymphocytopathic effects, other features in common with immunosuppressive MuLV and feline leukaemia viruses (FeLV). We therefore compared the amino acid sequences for p15E of Friend[18], Moloney[19], AKV[20], and Gross[21] murine leukaemia viruses (FLV, MoLV, AKV, GLV), FeLV[22], and mink-cell focus-forming viruses of Moloney[23] and AKR[24] origin (MMCF, AMCF) with the sequences of the envelope proteins of HTLV-I[25] and HTLV-II[26]. The sequences were analysed for homology using the PROTHOM computer program developed by Fristensky *et al.*[27].

Amino acid sequence homology between p21 of HTLV-I and HTLV-II and p15E of murine and feline leukaemia viruses. Residue 377 of the RTLV-I envelope and 373 of the HTLV-II envelope both correspond to residue 65 of the p21 protein.

As shown in the figure above there is a significant degree of homology (73%) between the various p15E proteins and HTLV-1 and HTLV-II which occurs in a 26-amino acid sequence located in the p21 region of HTLV. It is particularly noteworthy that the first 10 amino acids in this region are identical and that this region of homology occurs in almost the same region of the p15E and p21 molecules. The homology begins at residue 70 in p15E and at residue 377 of the HTLV-I envelope protein and at residue 373 of the HTLV-II envelope protein which both correspond to residue 65 of the p21 transmembrane protein[26].

The significance of such a well conserved region occurring in murine, feline, and human retroviruses is not yet clear. However, since dramatic immunosuppression is often associated with these viruses and purified p15E is immunosuppressive in a variety of systems, it will be particularly important to determine whether p21 of HTLV can also inhibit immune functions.

Islet activating protein analogous to p21 *ras*?

SIR — In a recent article on mutant *ras* protein and cell transformation, Rob Newbold considered the significance of new findings about p21 *ras* function and activation. In particular, similarities between p21 *ras* and the guanine nucleotide binding proteins which are responsible for stimulation and inhibition of adenylate cyclase were emphasized and an analogy drawn with the action of cholera toxin on G_S protein GTPase, implying that p21 *ras* might act in an analogous manner to cholera toxin, which exerts a strong proliferative stimulus on certain mammalian cells in culture.

I suggest that the analogy with cholera toxin is dubious in view of the fact that rat cells transformed by Kirsten sarcoma virus have been shown to contain less cyclic AMP and lowered adenylate cyclase activity. Therefore a closer analogy may be with the action of islet activating protein which reacts with Gi proteins to inhibit adenylate cyclase and reduce cyclic AMP. This would imply that decreased cyclic AMP assists proliferation.

Heritable IQ — a reason to bother

SIR — The recent article from Teasdale and Owen[1] prompts one to wonder about IQ genes. If intelligence is substantially heritable, is it determined by genes in a positive sense, such that better allelic combinations of IQ genes produce more intelligent people? This may seem to be the most parsimonious explanation, but parsimony is in the eye of the beholder.

That simple genetic mechanisms can account for conspicuously low IQ stirs no controversy (such as, phenylketonuria, Down's syndrome, Tay-Sachs), and most would agree that relatively mild homozygotic conditions can depress the IQ of afflicted persons (children who suffer from sickle cell anaemia or cystic fibrosis may test lower for IQ, on average, simply because they miss a great deal of school). Does this mean that such children have genetically heritable IQ? Does it mean, in the formal sense, that the disparity in IQ between them and normal children is attributable to variance in genes? Of course, it means exactly that — and yet the genes for beta haemoglobin and regulation of mucous production are not "IQ genes".

I am certain that my results on an IQ test would suffer if I were tested while I had a head cold. Imagine two boys reared in the same environment who are genetically identical except that one has an inherited sensitivity to ragweed. If they lived in a high ragweed area, such that the allergic one suffered from chronic congestion, would it be surprising to find that he tests slightly lower for IQ? Intelligence is a summary performance indicator, as distinct from an isolated component indicator (like how well a person's brain works), in the sense that suboptimal performance in any subsystem can have a negative impact. Variability in intelligence is perhaps analogous to the variability in horse power of a group of nominally identical engines, where quality of fuel represents the environmental component and fine tuning represents the genetic component. Performance is maximized when an engine is tuned for its operating conditions. A set of engines tuned in the tropics will not perform as well as when transported to Toronto. The question becomes, to what degree does the distribution of non-optimal non-IQ-genes account for heritable IQ?

The relative optimality of a gene is often environmentally specified. Teasdale and Owen, like others before them, found that the heritable component of IQ could be determined by segregation of a few alleles. ("The results for intelligence conform closely to what would be predicted by a simple polygenic model of genetic transmission . . . "). There are two ways this could happen: (1) there may be a universal handful of IQ genes that segregate appropriately, or (2) in any given environment, there may be a handful of genes for each of any one of hundreds of traits that can have a negative impact on IQ, and some of those handfuls segregate appropriately. If the former is the case, one wonders why alleles for superior IQ are not closer to fixation. Is there polymorphism for IQ because there were evolutionary environments in which intelligence was selected against?

Think about breathing through your nose in a steam bath. This is a genuine problem. Indeed, if you have a relatively long, thin, hairy nose (as typifies people from temperate zones and/or high altitudes — like Swedes and Ethiopians) it can be virtually impossible to pull enough air through that nose. But observe the steam bath breathing behaviour of someone with a wide, short, hairless nose (as typifies blacks and orientals indigenous to tropical wetlands). These people can breath superhumid air through their nose with no problem. Under the extreme condition of a steam bath, nose shape so strongly affects breathing efficiency that you can feel the difference by mechanically flaring your nostrils. Humans take over 10 million breaths a year. I submit that if we were all reared in steam baths, people with wide, short, hairless noses would have slightly higher mean IQ. This scenario is not silly because real noses in the real world are very differently adapted to conditions of humidity or dust. Among American racial and ethnic groups, only blacks and non-Japanese orientals have a conspicuous prevalence of lung disease[3]. Dust and airborne microorganisms can be a serious health hazard[4]. Noses have evolved accordingly.[5-7]

Can differences in nose shape (inherited) account for differences between black and white American IQ? It would be ridiculous to think so, but it should be considered equally ridiculous to assume that such factors have no effect. What about skin colour? More sunlight is required by dark skin to synthesize the same amount of vitamin D. Just as dark skin prevents hypervitaminosis-D in the tropics, so light skin facilitates D synthesis in temperate zones[8-10]. The question becomes, how many such factors are there? Dozens? Hundreds? More than enough to account for the portion of IQ variance which is heritable? Quite possibly. But this is not why the question is important.

The question is important because there are many factors that something could be done about if we knew what they were. People with dark skin in dark climates can get some extra sunshine. People with non-dust-trapping noses can have humidifiers in their homes during winter and take care to wear a dust mask when doing a dusty job. Unfortunately, looking for genetic differences that incidentally affect IQ is politically unacceptable because such investigations tacitly acknowledge the existence of such differences.

It may seem naive to think that things like clean air and sunshine could ameliorate genetic differences that contribute to differences in IQ. Fortunately, naivete is also in the eye of the beholder.

Raising the tone of DNA sequences

SIR — We assessed the potential for gene jingles following a lunchtime conversation two years ago. Hayashi and Munkata (*Nature* **310**, 96; 1984) appear to have used a purely arbitrary pitch-to-base assignment and ignored the complementary DNA strand altogether. We chose the notes D, A, F sharp, D, but have given some thought to base assignment of which there are 24 possibilities. We felt the complementary base triplet of each codon should produce a 'complementary' tune. Rather naively, we suspect, in musical terms, we took as complementary the quasi-mirror image of the notes on the stave (on the left of the figure). Eight of the possible 24 pitch-to-base assignments meet this requirement, but the assignment used by Hayashi and Munkata does not (on the right).

One of us (M.P.) sent short recorded DNA tunes to the other for the final selection of the pitch-to-base assignment by ear. No one assignment stood out as best, but the tunes of the promoter region CCAAT box were more pleasing musically than the 9-base repeat of collagen.

We are working towards the first public performance of 'Variations on a Cryptic Splice Junction' and the correspondence has given us renewed enthusiasm.

Formation of galaxies and large-scale structure with cold dark matter

The dark matter that appears to be gravitationally dominant on all scales larger than galactic cores may consist of axions, stable photinos, or other collisionless particles whose velocity dispersion in the early Universe is so small that fluctuations of galactic size or larger are not damped by free streaming. An attractive feature of this cold dark matter hypothesis is its considerable predictive power: the post-recombination fluctuation spectrum is calculable, and it in turn governs the formation of galaxies and clusters. Good agreement with the data is obtained for a Zeldovich ($|\delta_k|^2 \propto k$) spectrum of primordial fluctuations.

WHY are there galaxies, and why do they have the sizes and shapes that we observe? Why are galaxies clustered hierarchically in clusters and superclusters, separated by enormous voids in which bright galaxies are almost entirely absent? And what is the nature of the invisible mass, or dark matter, that we detect gravitationally roundabout galaxies and clusters but cannot see directly in any wavelength of electromagnetic radiation? Of the great mysteries of modern cosmology, these three may now be among the ripest for solution.

Because there is evidence that the mass of dark matter in the Universe exceeds that of the visible matter by at least an order of magnitude[1], the third question may hold the key to the first two. We now consider the hypothesis that the dark matter is cold[2-7], that is, that its thermal velocity is cosmologically negligible in the early Universe.

Most modern theories of the origin of structure in the Universe assume that the extreme inhomogeneity of the present Universe grew gravitationally from initially very small density fluctuations[8,9]. One hypothesis extensively explored[10-12] is that the dark matter (DM) consists of neutrinos of mass ~30 eV. Because these particles are noninteracting for $t \gtrsim 1$ s but are still relativistic at $t \sim 1$ yr when galaxy-size masses first come within the horizon ($R_{\text{horizon}} = ct$), they would freely stream away, smoothing out fluctuations of horizon size or smaller. We refer to such particles as hot DM, and to the phenomenon just mentioned as damping by free streaming. The mass of the neutrinos inside the horizon when they first become nonrelativistic is roughly $10^{15}\ M_\odot$, about the mass of a supercluster ($M_\odot$ is the solar mass). This is consequently the mass of the first structures to collapse gravitationally in a neutrino-dominated Universe.

It is also possible that the DM consists of elementary particles that decoupled thermally from the big bang much earlier than neutrinos. It can be shown that such particles would have lower number density today, and thus could be more massive (~1 keV) and become nonrelativistic sooner than neutrinos[13,14]. We refer to this as warm DM. The first structures to form in such a Universe would weigh about $10^{11}\ M_\odot$, about the mass of a typical galaxy[15-17].

In contrast, in a Universe dominated by cold DM, the free streaming damping mass is, by definition, smaller than galaxy masses. Below, we will discuss possible particle physics candidates for cold DM and explain why we believe it is more plausible that the Universe is dominated gravitationally by cold DM than by ordinary matter (baryons) or hot or warm DM. We next consider galaxy formation in the cold DM picture, and show that galaxy and cluster data compare favourably with the predictions of this model. We then discuss the extent to which the data constrain the cosmological density in the cold DM picture, and the evolution of superclusters and voids. The cold DM hypothesis seems to lead to a remarkably attractive theory for galaxy formation and to account for large-scale structure at least as well as any competing theory.

Evidence that dark matter is cold

Cold DM consists of particles having negligible thermal velocity with respect to the Hubble flow and having nongravitational interactions that are much weaker than the weak interactions[3,4]. A popular cold DM candidate is the axion[18], a pseudoscalar field proposed originally to avoid large CP (constant parity) violation in the strong interactions (which would imply, for example, much too large a value for the neutron electric dipole moment)[19-21]. Instanton effects generate a nonzero axion mass at the quark deconfinement temperature ($T \sim 10^2$ MeV), below which the axions act as a nonrelativistic, massive, pressureless fluid. The requirement that the axion density be less than the critical density implies that the axion mass $m_a \geqslant 10$[illegible] eV (refs 22-24), while the longevity of helium burning stars implies that $m_a < 10^{-1}$ eV (ref. 25). Thus, if axions exist, they may be cosmologically important, and, for $m_a \approx 10^{-5}$ eV, they would be gravitationally dominant. If axions comprise the dark halo of our Galaxy, laboratory experiments have recently been proposed that could detect them[26].

Another cold DM candidate particle is the photino, the spin $\frac{1}{2}$ supersymmetric partner of the photon. Photinos are thought to be the lightest supersymmetric particle, with $m_\gamma \gtrsim 0.5$ GeV (the lower limit corresponding to cosmological critical density)[27]. As photino annihilation at high temperatures is incomplete, the remnant photinos can, because of their large mass, contribute a critical density today.

A third cold DM candidate is black holes[28,29] of mass $10^{-16}\ M_\odot \leqslant M_{\text{BH}} \leqslant 10^6\ M_\odot$, the lower limit implied by the non-observation of γ rays from black hole decay by Hawking radiation, and the upper limit required to avoid disruption of galactic disks and star clusters[30,31]. Stronger but more controversial upper limits are $M_{\text{BH}} < 10^2\ M_\odot$ from dwarf spheroidal haloes[32] and $M_{\text{BH}} < 10^{-2}\ M_\odot$ from the non-observation of focusing of quasar cores[33].

Another exotic cold DM candidate, recently proposed by Witten, is "nuggets" of u-s-d symmetric quark matter[34]. There is thus no shortage of cold DM candidate particles—although there is no direct evidence that any of them actually exists. Our motivation for considering the hypothesis that the Universe is dominated by cold DM is twofold. First, there is more than a little evidence against baryonic, hot, and warm DM. Moreover, a cold DM Universe correctly predicts many of the observed properties of galaxies, including their range of masses, irrespective of the identity of the cold particle.

The most conventional assumption might be that DM is baryonic, since we know that baryons pervade the Universe. There are, however, three arguments that make a nonbaryonic form of DM more plausible. First, if DM consists of baryons, it must be clumped into objects with mass $\ll M_\odot$ to avoid nuclear burning and the emission of too much radiation[35], and there is no compelling theory for the formation of such a large density of objects of planetary mass or smaller. The difficulties with other possible forms of baryonic dark matter have been reviewed elsewhere[36]. The second argument involves the observed deuterium abundance, $D/H = (1\text{-}4)\times 10^{-5}$ (by number), which provides a lower limit on the primordial D abundance because deuterium is readily consumed but not produced in stars. This then corresponds to an upper limit for the baryonic density parameter (ratio of baryon density to critical density) of $\Omega_b \leq 0.035h^{-2}\,(T_0/2.7)^3$ (ref. 37), where T_0 is the present temperature of the microwave background radiation and h is Hubble's constant expressed in units of $100\ \text{km s}^{-1}$ Mpc. (Observationally, $1/2 \leq h \leq 1$.) However, there is also strong observational evidence that the total density parameter $\Omega \geq 0.1$. Therefore a baryon dominated Universe ($\Omega = \Omega_b$) is consistent with the deuterium limit only for Ω and h very near their observational lower limits. Finally, the existence of galaxies and clusters today requires that perturbations in the density must have become nonlinear before the present epoch. In a baryonic Universe, for adiabatic perturbations at recombination, this implies present-day fluctuations in the microwave background much larger than the present observational upper limits[38,39]. For baryonic DM, this problem can be avoided if the primordial fluctuation spectrum is isothermal rather than adiabatic, contrary to grand unified models of baryosynthesis[40,41], or if there is significant reheating of the intergalactic medium after recombination[42]. For nonbaryonic DM, on the other hand, the predicted fluctuations in the microwave background can be consistent with the observations as the fluctuations in the baryon-photon fluid are small at recombination and only later grow to the same size as fluctuations in the DM.

The neutrino dominated picture of galaxy formation also has serious weaknesses. Studies of nonlinear clustering (on scales $\lambda < 10$ Mpc) show that supercluster collapse must have occurred quite recently, at redshift $z_{sc} < 2$ (refs 43, 44). This is also consistent with a study of streaming velocity in the linear regime ($\lambda > 10$ Mpc), which indicates $z_{sc} < 0.5$ (ref. 45). However, the best limits on galaxy ages coming from globular clusters and other stellar populations, plus the possible association of QSOs with galactic nuclei, indicate that galaxy formation took place before $z = 3$ (ref. 46). This is inconsistent with the neutrino 'top-down' theory, in which superclusters form before galaxies rather than after them.

Another problem with the neutrino picture is that large clusters of galaxies can accrete neutrinos more efficiently than ordinary galactic haloes, which have lower escape velocities. One-dimensional numerical simulations predict that the ratio of total-to-baryonic mass M/M_b should be ~ 5 times larger for clusters ($\sim 10^{14}\,M_\odot$) than for ordinary galaxies ($M \sim 10^{12}\,M_\odot$)[47]. While there is evidence that mass-to-light ratio M/L does increase with scale, there is also considerable evidence that the more physically meaningful ratio of total-to-luminous mass M/M_{lum} remains constant from large clusters through groups of galaxies, binary galaxies, and ordinary spirals. (M_{lum}, which is the mass visible in galactic stars and gas plus hot, X-ray emitting gas, is $\leq M_b$, as an unknown fraction of the baryons is

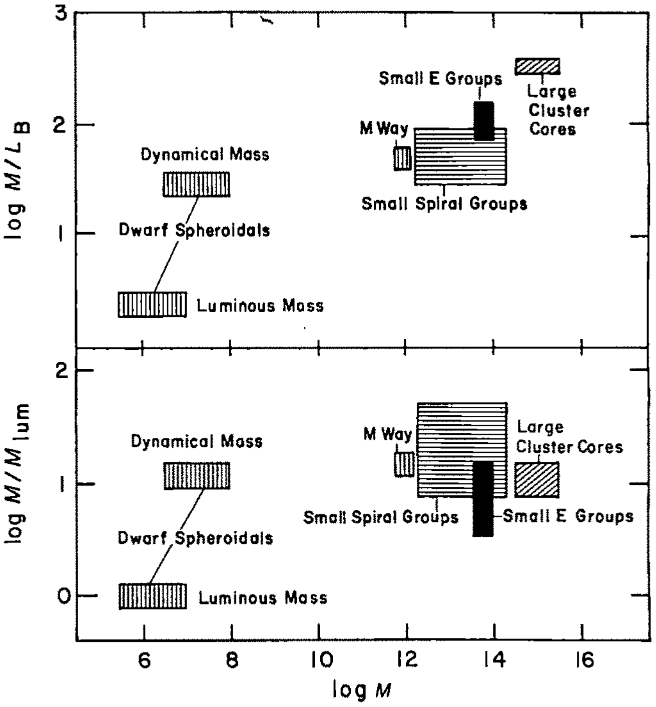

Fig. 1 Mass-to-light ratio, M/L_B, and total-to-luminous mass, M/M_{lum}, for structures of various size in the Universe. The data come from Table 1. Although M/L_B increases systematically with mass, the more physically meaningful ratio M/M_{lum} appears to be constant on all scales within the errors. If the velocity dispersion data for the dwarf spheroidal galaxies are interpreted to imply heavy haloes, the upper estimates result. The lower estimates follow from assuming that all the mass is visible. We believe the former estimate to be more realistic.

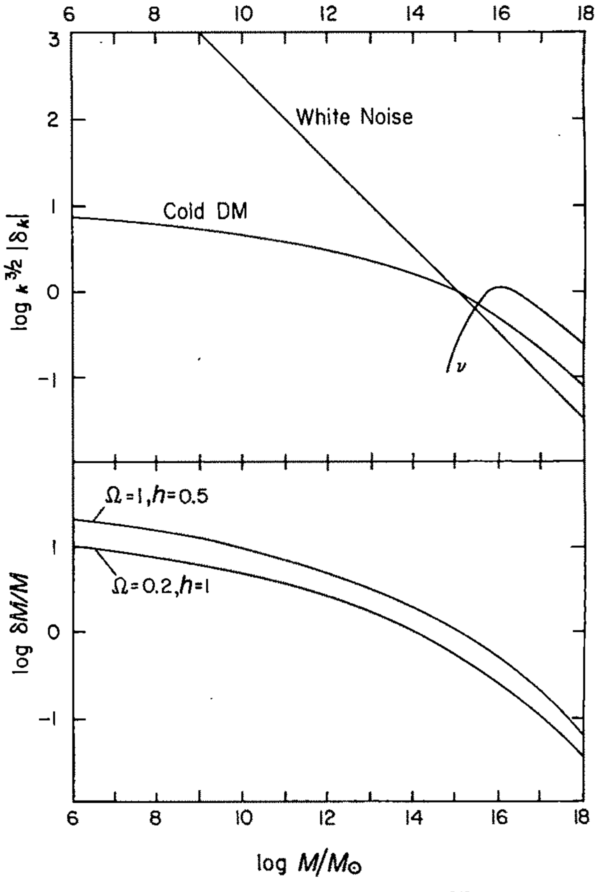

Fig. 2 Density fluctuations as a function of mass. *a*, $k^{3/2}|\delta_k| = \delta\rho/\rho(M)$, where $M = 4\pi^4\rho_0/3k^3$, for isothermal white noise ($n=0$), and adiabatic Zeldovich ($n=1$) neutrino[16] and cold DM spectra. *b*, r.m.s. mass fluctuation within a randomly placed sphere containing mass M for cold DM, $n=1$, and ($\Omega=1$, $h=0.5$), ($\Omega=0.2$, $h=1$).

invisible—for example, in the form of diffuse ionized intergalactic gas at $T \sim 10^4$ K.) This is illustrated in Table 1 and Fig. 1, where we have plotted observed data for M/L and $M/M_{\rm lum}$. The fact that the total-to-luminous mass of rich clusters is similar to that of galaxies including their massive haloes, even though the clusters' mass-to-light ratio is larger, is due mainly to the different stellar population in the E and S0 galaxies in rich clusters plus the large contribution of X-ray emitting gas to $M_{\rm lum}$. In very rich clusters such as Coma, there is perhaps ~2–5 times as much mass in hot gas as there is in stars.

Finally, preliminary velocity dispersion data for Draco, Carina, and Ursa Minor[48-50] as well as theoretical arguments[51] suggest that a significant amount of DM may reside in dwarf spheroidal galaxies. Because of the low velocity dispersion of dwarf galaxies, phase space constraints give a lower limit of $m > 500$ eV for the mass of particles comprising this DM[32]. The present velocity dispersion estimates are uncertain owing to possible stellar oscillations, mass outflow, and binary motions, but these effects can be discovered and eliminated with careful monitoring. Taken at face value, however, the existing mass limit of 500 eV would rule out neutrinos completely.

Although warm DM provides a natural (free streaming) scale for ordinary galaxies, it cannot account for massive haloes in dwarf spheroidals even though the warm DM mass is actually, if barely, consistent with the phase space constraint. This is because free streaming damps out fluctuations with mass $<10^{11}\,M_\odot$, so dwarf galaxies with mass $\sim 10^7\,M_\odot$ can form in this picture only by the fragmentation of much larger scale galactic masses. Because dwarf galaxies with escape velocity $\sim 10\,{\rm km\,s^{-1}}$ would capture only a small fraction of the warm DM particles, whose velocity dispersion would be $\sim 100\,{\rm km\,s^{-1}}$, typical of ordinary spirals, one would expect $M/M_{\rm lum}$ to be much smaller in dwarf galaxies than in spirals. However, the dynamical mass data on dwarf spheroidals shown in Fig. 1 suggest a similar value for the ratio of total-to-luminous mass. In view of the great importance of dwarf spheroidal haloes to constraints on warm as well as hot DM, it is clearly urgent to continue the monitoring programme on velocity dispersions mentioned above.

Recently proposed models having two or more kinds of possibly unstable DM[52-58] may be easier to reconcile with observations than models with one stable DM species, in part because of their additional adjustable parameters. Such models are, however, beyond the scope of this paper.

Galaxy formation with cold dark matter

The key features of galaxy formation in the cold DM picture are these: the DM fluctuation spectrum at recombination is determined by a small number of physical parameters; after recombination (at $z_{\rm rec} \approx 1{,}300$) the amplitude of the baryonic fluctuations rapidly grows to match that of the DM fluctuations; smaller-mass fluctuations grow to nonlinearity and virialize, and then are hierarchically clustered within successively larger bound systems; and finally the ordinary matter in bound systems of total mass $\sim 10^{8-12}\,M_\odot$ cools rapidly enough within the DM haloes to form galaxies, while larger mass fluctuations form clusters.

To calculate the growth of initially small perturbations and their ultimate gravitational collapse into condensed systems, one must first determine an initial spectrum for density perturbations in the very early Universe. We assume here that the initial fluctuations are adiabatic, which is consistent with fashionable particle theories in which a small excess of baryons over antibaryons is generated by the decay of supermassive grand unified theory particles[40,41]. Then the mass (or energy) density at any point can be written as $\rho(r,t) = \rho_0(1+\delta)$, where $\rho_0(t)$ is the average density in the Universe and δ represents the fractional density perturbation in the synchronous gauge. If the fluctuation spectrum is characterized by a power law distribution, then the r.m.s. fluctuation on mass scale M can be written $\delta \propto M^{(-1/2)(-n/6)}$, which corresponds to a Fourier power spectrum $|\delta_k|^2 \propto k^n$. Alternatively, we can characterize the perturbations on mass scale M when that mass scale crosses (first comes within) the horizon as $\delta_{\rm H} = \varepsilon(M/M_0)^{-\gamma}$, where M_0 is the present horizon mass and $n = 6\gamma + 1$. To avoid having too much power on either large or small scales requires $\gamma \approx 0$, which corresponds to $n \approx 1$. Limits on the large-scale variation of the microwave background further imply $\varepsilon \lesssim 10^{-4}$. The case $n = 1$ is commonly referred to as the constant curvature or (Harrison-Peebles-) Zeldovich[59-61] spectrum, and is predicted in inflationary models. It has recently been shown that not only inflation but also $\varepsilon \approx 10^{-4}$ can be arranged in suitably fine-tuned grand unified theories[62-64]. The Zeldovich spectrum also arises automatically if the fluctuations are due to cosmic strings[65,66]. We show below that $n = 1$ is, furthermore, in best agreement with galaxy and cluster data.

The first study of the growth of cold DM fluctuations was the numerical calculation of Peebles[2], who included cold DM, photons, and ordinary matter. Two of us (G.R.B. and J.R.P.)[3-[illegible]] extended these numerical calculations to include three massless neutrino species. Fluctuations having mass $M < M_{\rm eq} = 2 \times 10^{5}\,(\Omega h^2)^{-2}\,M_\odot$ cross the horizon when the Universe is still radiation dominated, that is, when $z > z_{\rm eq} = 2.5 \times 10^4\,\Omega h^2$. After such fluctuations cross the horizon, their neutrino components dissipate by free streaming, and the remaining photon and charged particle perturbations oscillate as an acoustic wave (whose amplitude is ultimately damped by photon diffusion for[67] $M < M_{\rm Silk} \approx 3 \times 10^{13}\,\Omega_{\rm b}^{-1/2}\Omega^{-3/4}h^{-5/2}M_\odot$). As a result, the main driving terms for the growth of cold dark matter fluctuations $\delta_{\rm DM}$ decrease, and consequently $\delta_{\rm DM}$ begins to grow only very slowly until the Universe becomes (dark) matter dominated at $z_{\rm eq}$, after which $\delta_{\rm DM} \propto a = 1/(1+z)$ until $z \approx \Omega^{-1}$. This stagnation of the growth of DM fluctuations between the epochs of horizon crossing and matter domination is called 'stagspansion'[3-7].

Because fluctuations with $M < M_{\rm eq}$ grow very little during the stagspansion era and as fluctuations on all scales grow at essentially the same rate after the Universe becomes matter dominated, an initial Zeldovich spectrum, $\delta_{\rm DM} \propto M^{-2/3}$, evolves to a much flatter spectrum for $M < M_{\rm eq}$ by the time of recombination. In Fig. 2 we plot the resulting cold DM fluctuation spectrum at present (ignoring the nonlinear evolution which is important for $\delta \gtrsim 1$, as discussed below; thus the plotted spectrum δ_k is larger than the spectrum at recombination by a constant factor). The quantity plotted in Fig. 2*a*, $k^{3/2}|\delta_k|$, roughly

‡ From ref. 120.

§ $M_{\rm gas}/M_{\rm lum}$ is calculated as the product of two factors: $(M_{\rm gas}/M) \times (M_{\rm lum}/M)^{-1}$. $M_{\rm gas}/M = 0.10^{+0.02}_{-0.05}$ from ref. 121 for 14 X-ray clusters. Formal clusters have been increased to allow for the unknown gas distribution outside the core and possible settling of gas relative to galaxies or vice versa. $M_{\rm lum}/M$ is $(M_* + M_{\rm gas})/M$, where M_*/M is the fractional mass in stars. It may be calculated as $(M/L_{\rm B})_*(M/L_{\rm B})^{-1}$, where $(M/L_{\rm B})_*$ is the stellar mass-to-light ratio. For E and S0 galaxies in large clusters, $(M/L_{\rm B})_*$ appears to be about 6 (ref. 1).

‖ $L_{\rm V}$, $M_{\rm gas}$, and M from ref. 122 based on five groups. $L_{\rm V}$ corrected to B(0) system based on data provided by Kriss (personal communication). Comparison with Beers *et al.*[123] suggests that M may be underestimated by a factor of two. Quoted errors take this into account.

represents the spatial density fluctuation δ as a function of total mass $M=4\pi^4\rho_0/3k^3$. Also sketched are the fluctuation spectra in the hot DM scenario and in an isothermal scenario with white noise fluctuations. Note that the hot DM model requires more power on large scales today to form superclusters by $z\approx 2$. Figure 2*b* shows cold DM fluctuation spectra plotted in another form, $\delta M/M$, which represents the r.m.s. mass fluctuation within a randomly-placed sphere of radius R containing mass M. Following Peebles[2], we have normalized the curves so that, at the present epoch, $\delta M/M=1$ at $R=8h^{-1}$ Mpc.

Even though baryonic fluctuations do not grow (and are damped for $M<M_{\rm Silk}$) before recombination, after recombination the baryons 'fall into' the DM perturbations so that quickly $\delta_b=\delta_{\rm DM}$ (refs 68, 69). This will occur if $\Omega_{\rm DM}\delta_{\rm DM}\gg\Omega_b\delta_b$, as we expect, and if the baryonic fluctuation mass exceeds the baryonic Jeans mass[6] $M_{J,b}\sim 10^6\,\Omega_b\Omega^{-3/2}h^{-1}(T_b/T)^{3/2}M_\odot$, where T_b is the temperature of the baryonic gas and T is the photon temperature. On scales smaller than this, the pressure of the baryonic gas prevents it from developing the same density contrast δ as the cold DM. The value of T_b/T is kept close to unity for $z>100$ by the coupling of the residual free electrons with the radiation, but for smaller z it falls off approximately as $(1+z)$. This means that at $z\approx 10$, $M_{J,b}$ may be as small as $\sim 10^3\,M_\odot$.

At any mass scale M, when the fluctuation $\delta M/M$ approaches unity, nonlinear gravitational effects become important. The fluctuation then separates from the Hubble expansion, reaches a maximum radius, and begins to contract. Spherically symmetric fluctuations, for example, contract to about half their maximum radii. During this contraction, violent relaxation due to the rapidly varying gravitational field converts enough potential energy (PE) into kinetic energy (KE) for the virial theorem, $\langle PE\rangle=-2\langle KE\rangle$, to be satisfied. After virialization, the mean density within a fluctuation is roughly eight times the density corresponding to the maximum radius of expansion[8].

As the cold-DM fluctuation spectrum $\delta M/M$ is a decreasing function of M, smaller mass fluctuations will, on the average, become nonlinear and begin to collapse at earlier times than larger mass fluctuations. Smaller mass fluctuations are themselves typically clustered within larger mass perturbations, which go nonlinear later. This hierarchical clustering of smaller systems into larger and yet larger gravitationally bound systems begins at the baryon Jeans mass, $M_{J,b}$, and continues until the present. The baryonic substructures within larger mass clusters will then be disrupted by virialization of the clusters unless significant mass segregation between baryons and DM has occurred before cluster virialization. Hence, to maintain their existence as a separate substructure, the baryons must cool and gravitationally condense within their massive DM haloes before virialization occurs on larger scales[70].

Figure 3 shows the baryonic number density n_b plotted against temperature T (or halo velocity dispersion) for virialized spherically symmetric protocondensations resulting from an initial Zeldovich spectrum of cold DM fluctuations. The simplifying assumption of sphericity is not expected to be an unreasonable approximation for hierarchical clustering. Two cases are considered: $\Omega=1$ and $h=0.5$ (solid lines in Fig. 3), and $\Omega=0.2$ and $h=1$ (dashed lines). The curves assume that the protocondensations have virialized, but that the baryons have not yet cooled and condensed. The curves labelled 1σ assume that for each mass scale, $\delta M/M$ has the r.m.s. value; those labelled 2σ correspond to fluctuations $\delta M/M$ twice as great; and so on. For given total mass M, the distribution of values of $\delta M/M$ spreads out along lines of constant M (light diagonal lines in Fig. 3). We have also shown in Fig. 3 the present positions of clusters and groups of galaxies and of individual galaxies, including dwarf spheroidals. Note that different types of galaxies, the Hubble sequence, are spread out in this diagram.

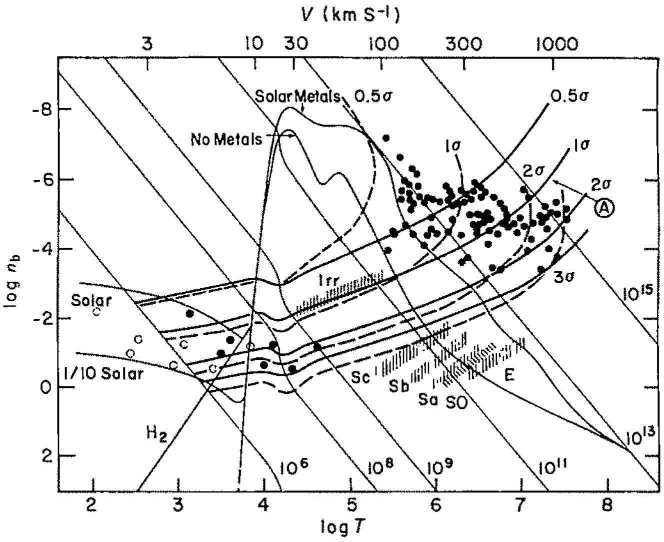

Fig. 3 Baryon density n_b versus three-dimensional, r.m.s. velocity dispersion V and virial temperature T for structures of various size in the Universe. The quantity T is $\mu V^2/3k$, where μ is mean molecular weight ($\approx$0.6 for ionized, primordial H+He) and k is Boltzmann's constant. Dots at upper right represent nearly all groups and clusters within 5,000 km s^{-1} in the CfA catalogue[82]. Baryon density is obtained from total density assuming $\rho_b/\rho=0.1$ (see Table 1), where ρ is defined as $M/(4\pi R_{\rm vir}^3/3)$, M is total mass, and $R_{\rm vir}$ is GM/V^2. Catalogue groups are chosen to exceed a minimum threshold luminosity density. Their minimum baryon density should thus fall on a horizontal line, slightly modified by the higher M/L of rich clusters, as is observed. Point A represents Abell clusters of richness 2 and 3 studied by Dressler[120]. Here $R_{\rm vir}=3.0\,R_{\rm eff}$, valid for a de Vaucouleurs cluster profile[125]. The quantity T for clusters corresponds to central velocity dispersion, with the arrow indicating the effect of the falloff in velocity dispersion at large radii observed in the Coma cluster[126,127]. For galaxies, $M_{\rm lum}$ is set equal to $(M_{\rm lum}/L_B)\times L_B$, where L_B is blue luminosity. Assumed values of $(M_{\rm lum}/L_B)$: E=8, S0=6, Sa=4, Sb=2.5, Sc=1.5, Dw. Irr=1.00, Dw. Spheroidal=2.5 (all but the last are based on $h=0.5$). Galaxy radii are approximate virial radii, assuming that the baryonic components of galaxies are self-gravitating (to obtain a radius consistent with the definition used for groups and clusters above). To achieve this, isophotal radii from various sources have been appropriately scaled, as follows: E–Sb, $R_{\rm vir}=R_{25}$ (refs 128–131); Sc, $R_{\rm vir}=1.24\,R_{25}$ (ref. 132); Dw–Irr, $R_{\rm vir}=1.24\,R_H$ (ref. 133); Dw–Sph. $R_{\rm vir}=0.70\,R_{\rm tid}$ (ref. 51). Velocities: E–S0, $V=\sqrt{3}\times\sigma$ (nucleus) (refs 129, 134); Sa–Sc, $V=v_{\rm rot}^{\rm max}$ (refs 130, 131, 132); Dw–Irr, $V=1/2$ FWHM (Δv) (ref. 133), corrected for inclination. Dw Spheroidals are plotted twice; open circles, $M=2.5\,L_B$ (stars only) and $V=(GM/R_{\rm vir})^{1/2}$; large dots, $M=30\,L_B$ (stars plus dark matter[48–51]), with V as before. Light diagonal lines represent the masses of self-gravitating bodies with the indicated values of n_b and T and assuming $\rho_b=0.1\rho$. The discontinuities near 10^4 K are due to the effects of H and He ionization. Cooling curves[78,135,136] (medium lines) separate regions where cooling is efficient ($\tau_{\rm cool}<\tau_{\rm dyn}$, lower region) from regions where it is inefficient ($\tau_{\rm cool}>\tau_{\rm dyn}$, upper region). All curves assume a residual electron fraction after recombination of 10^{-4}, consistent with $\Omega_b/\Omega=0.1$. Model curves represent the equilibria of structures that collapse dissipationlessly from the cold dark matter initial fluctuation spectra of Fig. 2 with $n=1$. DM haloes and groups and clusters of galaxies should lie on these curves, whereas the baryon components of galaxies should lie below due to baryonic dissipation. The curves labelled $v\sigma$ refer to fluctuations with $\delta M/M$ equal to v times the r.m.s. value shown in Fig. 2. Heavy curves: $\Omega=1$, $h=0.5$; dashed curves: $\Omega=0.2$, $h=1$. Model curves appear to pass through groups and clusters in about the right place, and the horizontal spread in T is roughly as expected for a gaussian distribution in $\delta M/M$. Baryon components of galaxies lie below the loci for dissipationless collapse and generally within the region where strong baryonic cooling is expected. Dwarf spheroidal galaxies lie near the beginning of the clustering hierarchy and may be typical of the earliest structures to collapse (see ref. 73). Hubble types are spread out along different loci, perhaps due in part to different baryon collapse factors (Es larger, Irrs smaller) and in part to intrinsic differences in initial $\delta M/M$ (see also Fig. 4).

Baryonic cooling moves structures downward in Fig. 3, below the model curves. Baryons can radiatively cool through collisional excitation of atoms and molecules, and by Compton cooling off the cosmic background radiation; Fig. 3 correspondingly includes the medium solid curves labelled 'No metals' and 'Solar metals', 'H_2', and 'Compton'. Below these curves the baryonic cooling time is shorter than the dynamical time and above them the reverse is true[71]. Figure 3 immediately shows that, while the Hubble sequence of galaxies shows strong evidence for baryonic cooling and dissipation (core condensation in heavy haloes), dwarf spheroidals are only marginally able to cool, and groups and clusters of galaxies have too long a cooling time to have dissipated much energy on their scale[72,73].

On average, for the cold DM fluctuation spectrum, what range of total masses yields baryon condensation within a massive halo? Let us first consider large galaxies. Naively, Fig. 3 suggests that there is an upper bound for galactic masses of $M \leqslant 10^{12}\ M_\odot$, where the baryonic cooling time for gas of primordial composition begins to exceed the dynamical time. More massive galaxies could form in dense regions, where perhaps an early generation of Population III stars enriched the remaining baryonic gas with metals. Actually, the situation is likely to be more complicated, with many large galaxies formed by the merger of smaller ones. The resulting galaxy mass distribution arises from competition between hierarchical clustering and decreasing galaxy collision cross-sections due to dissipation, and it is thus difficult to calculate reliably. Regarding the smallest galaxies, collisional excitation of atomic hydrogen provides a lower limit of $M \geqslant 10^8\ M_\odot$, corresponding to virialized baryonic temperature $T_b \geqslant 10^4$ K. This range of protogalactic total masses, $10^8\ M_\odot \leqslant M \leqslant 10^{12}\ M_\odot$, encompasses virtually all the mass that is observed to comprise galaxies. For protogalaxies in this mass range, the velocity dispersion of the baryons will initially remain nearly constant ($T \approx$ constant) as they condense within the gravitational potential of the virialized (and presumably roughly isothermal) DM halo. When the baryon density increases enough that their gravitational potential dominates that of the halo, the baryons' velocity dispersion will rise as they continue to dissipate energy and condense. Baryonic contraction is finally halted by rotation and perhaps, in some protogalaxies, by star formation (see below).

The collapse of fluctuations with mass $M > 10^{13}\ M_\odot$ leads to clusters of galaxies in this picture. In clusters, only the outer parts of member galactic haloes are stripped off by collisions—the inner baryonic cores are able to contract to form the observed stellar systems. More of the baryons in the richest clusters are observed to be in the form of hot gas than in galaxies, as we have already mentioned in connection with Fig. 1. Perhaps this is because rich clusters tend to contain high-density cores, which collapse early, simultaneously with many of the galaxies they contain.

Can the cold DM picture account for the wide range of morphologies displayed by clusters of galaxies in X-ray[74] and optical-band[75] observations, ranging from regular, apparently relaxed configurations to complex, multicomponent structures? Preliminary results are encouraging. In particular, simulations show that large central condensations form quickly and can grow by subsequent mergers to form cD galaxies if most of the DM is in haloes around the baryonic substructures, as expected for cold DM, but not if the DM is distributed diffusely[76,77].

What happens to small clouds whose baryonic mass M_b lies in the range $M_{J,b} < M_b < 10^{7\text{-}8}\ M_\odot$ and for which $T_b < 10^4$ K after virialization? For a primordial element abundance, the molecular cooling time (primarily due to H_2) is less than the dynamical time for fluctuations that satisfy

$$M_b > M_{C,b} \approx 4.1 \times 10^6 (\Omega h^2)^{-0.917} \left(\frac{Y_e}{10^{-4}}\right)^{-0.625} \left(\frac{\Omega_b}{0.1\Omega}\right)^{-1.04} \times \left(\frac{1+z_t}{10}\right)^{-2.75} M_\odot$$

where z_t is the redshift of maximum expansion of the fluctuation. (This result uses the cooling rates given by Yoneyama[78] and assumes the simple 'top hat' model of collapsing fluctuations. It corrects an equation given in ref. 17.) The quantity Y_e, the fraction of free electrons, is essentially the fraction that escapes recombination as the universe cools below ~1,000 K, and is roughly $10^{-4}(\Omega_b/0.1)^{-1}\Omega^{1/2}h^{-1}$. Systems with $M_b < M_{C,b}$ will persist as pressure supported clouds until they are disrupted by the virialization of larger scale clusters. Clouds having $M_b > M_{C,b}$ can dissipate energy and collapse, although the influence of rotation and the efficiency of fragmentation are poorly understood. The end product may be an irregular or dwarf spheroidal galaxy. Other possibilities such as a protoglobular cluster or one or more very massive objects (VMOs) would require greater contraction and are likely to be inhibited by angular momentum.

Moreover, it is unclear what fraction of the original baryonic mass can be retained by such small clouds rather than expelled. There is—despite the uncertainties—a strong probability that energy output from fragmented subsystems can influence the gas that remains uncondensed, thereby exerting a feedback on further condensation. In particular, UV emission from massive or supermassive stars can photoionize the remaining diffuse baryons, raising T_b up to 10^4 K. If such stars radiate a fraction q_{UV} of their Eddington luminosity in Lyman continuum photons, then the entire baryonic medium can be ionized even by a mass fraction of stars as low as $\sim 3 \times 10^{-5}/q_{UV}$. If the baryonic gas is re-ionized in systems with total mass $M \leqslant 10^6\ M_\odot$, the baryons become so hot that they flow out of the cloud, whose gravitational field is not strong enough to bind them.

This may explain the origin of dwarf spheroidal galaxies, with $10^6\ M_\odot < M < 10^8\ M_\odot$, which show little evidence of dissipation in Fig. 3. As the baryons in these systems begin to condense through molecular cooling, if fragmentation and star formation are very efficient the baryons quickly turn into stars and condensation ceases. On the other hand, if a fraction of the baryons fragment into stars having strong UV luminosity, the remaining baryons are heated until they leave the system, and dissipation will again cease. The apparent absence of dissipation in dwarf spheroidals could also be due to stripping of their baryons in encounters with more massive systems[32], which would move the dwarfs upward in Fig. 3.

In the cold DM scenario, globular clusters are probably not primordial objects. For one thing, there is no evidence that they have massive haloes (although, as Peebles[79] points out, there is not much direct contrary evidence either). Furthermore, if truly primordial, they should be distributed in the Universe like DM whereas, at least within galaxies, they seem to have dissipated and condensed like the other baryonic matter. However, the existence of 'standard objects' inside galaxies with mass $\sim 10^6\ M_\odot$ demands some explanation. In the model discussed here, there is a natural mass scale of order $M_{g,b} \sim M_{Gal,b}(T_{virial}/10^4\ K)^{-2}$, where $M_{Gal,b}$ is the baryonic mass within a galaxy; $M_{g,b}$ is the Jeans mass of a cloud at 10^4 K in pressure balance with protogalactic gas at the virial temperature[80]. During the dissipation phase of galaxy formation, the gas might be likely to have a two-phase structure with a hot phase at T_{virial} and a cool phase at $\sim 10^4$ K, in which case subcondensations of mass $M_{g,b}$ would be expected with density contrast $\approx T_{virial}/10^4$ K. We identify these with protoglobular clusters (noting that the considerations of Fall and Rees[81] could further limit the mass range).

Galaxies and clusters

While the n_b–T plot (Fig. 3) is useful for comparing data and predictions with the cooling curves, it is also useful to consider total mass M versus T, as in Fig. 4. This avoids having to take into account the differing amounts of baryonic dissipation suffered by various galaxies. The heavy solid and dashed curves again correspond to the $n = 1$ cold DM spectrum, for ($\Omega = 1$, $h = 0.5$) and ($\Omega = 0.2$, $h = 1$) respectively. It is striking that galaxies in the M–T diagram lie along lines of roughly the same slope as these curves. This occurs because the effective slope of the $n = 1$ cold DM fluctuation spectrum in the galaxy mass range is $n_{eff} \approx -2$, which corresponds to the empirical Tully-Fisher and Faber-Jackson laws: $M \propto v^4$. The light dashed lines in Fig. 4 are the postvirialization curves for primordial fluctuation spectra with $n = 0$ (white noise) and $n = 2$. The $n = 1$ (Zeldovich) spectrum is evidently the one that is most consistent with the data.

The points in Fig. 4 represent essentially all of the clusters identified by Geller and Huchra[82] in the CfA catalogue within 5,000 km s^{-1}. The cluster data lie about where they should on the diagram, and even the statistics of the distribution seem roughly to correspond to the expectations represented by the 0.5, 1, 2, and 3σ curves. Note that the galaxies and clusters are neatly separated by the Compton cooling line of Fig. 3, suggesting that the era of galaxy formation ceased in the Universe when Compton cooling off microwave background photons became inefficient (J. E. Gunn, personal communication).

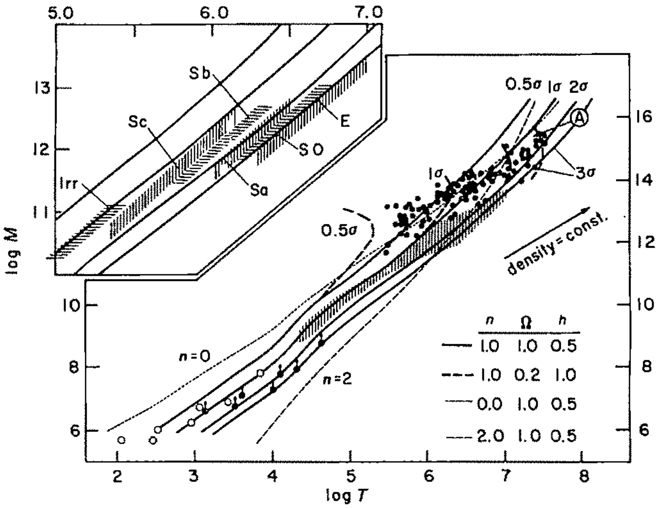

Fig. 4 Total mass M versus virial temperature T. Data sources and symbols are as in Fig. 3. M for groups and clusters is total dynamical mass. For galaxies, M is assumed to be 10 $M_{\rm lum}$ (see Fig. 3 legend). If Dw spheroidals actually have $M/L_{\rm B}=30$, they may have suffered baryon stripping[32], in which case M is a lower limit (arrows). Details of the region occupied by massive galaxies are shown in the inset, upper left. In addition to the $n=1$ models from Fig. 3, two 1σ curves for $n=0$ and $n=2$ are also shown (light dashes). Either set of curves for an $n=1$ (Zeldovich) spectrum provides a good fit to the observations over 9 orders of magnitude in mass. Curves with $n=0$ and $n=2$ do not fit as well. The apparent gap between galaxies and groups and clusters in Fig. 3 (which stems from baryonic dissipation) vanishes in this figure, and the clustering hierarchy is smooth and unbroken from the smallest structures to the largest ones. The Fisher–Tully and Faber–Jackson laws for galaxies ($M\propto V^4$ or T^2) arise naturally as a consequence of the slope of the cold DM fluctuation spectrum in the mass region of galaxies. Groups and clusters are distributed around the $n=1$ loci about as expected. The apparent upward trend among the groups is not physically meaningful but arises from their selection as density enhancements above a minimum threshold (see caption, Fig. 3, and constant-density arrow, this figure). The exact locations of galaxies are uncertain. In particular, the temperatures of Es and S0s may be overestimated owing to the use of nuclear rather than global velocity dispersions. The masses of Dw. Irrs may also be too low owing to neglect of mass in H_2. Taken at face value, however, the data suggest that early-type galaxies (Es and S0s) arise from high-$\delta M/M$ fluctuations, whereas late-type galaxies (Scs and Irrs) arise from low-$\delta M/M$ fluctuations. Groups and clusters appear to fill a wider band than galaxies. If real, this difference may indicate that low-$\delta M/M$ fluctuations on the mass scale of galaxies once existed but did not give rise to visible galaxies. This suggests further that galaxy formation, at least in some regions of the Universe, may not have been fully complete and that galaxies are therefore not a reliable tracer of total mass. The sharp demarcation line between galaxies and clusters corresponds to the Compton cooling limit in Fig. 3 and suggests that galaxy formation ceased when Compton cooling off the microwave background became inefficient.

Note that spiral galaxies lie roughly along the 1σ curve while elliptical galaxies lie along the 2σ curve. Although this displacement is not large compared with the uncertainties, it is consistent with the fact that more than half of all galaxies are spirals, while only ~15% are ellipticals. We have suggested elsewhere[83] that, in hierarchical clustering scenarios, the higher σ fluctuations will develop rather smaller angular momenta, as measured by the dimensionless parameter $\lambda(=JE^{1/2}G^{-1}M^{-5/2})$. This difference seems to exist with either white noise or a flatter spectrum, but to be larger in the latter case. If high σ fluctuations have little angular momentum, their baryons can collapse by a large factor in radius, forming high-density ellipticals and spheroidal bulges, as shown in Fig. 3. Because, with a flat spectrum, higher σ fluctuations occur preferentially in denser regions destined to become rich clusters (the statistics of such correlations can be treated[84] by the methods of Peebles[6]), one expects to find more ellipticals there—as is observed. Indeed, the rich clusters lie along the same 2 and 3σ curves in Fig. 4 as do the elliptical galaxies.

Presumably the collapse of the low-λ protoelliptical galaxies is halted by star formation well before a flattened disk can form, yielding a stellar system of spheroidal shape. The mechanism governing the onset of star formation in these systems is unfortunately not yet understood, but may involve a threshold effect which sets in when the baryon density exceeds the DM halo density by a sufficient factor[70,72]. Disks (spirals and irregulars) form from more typical higher-λ protogalaxies, which, for a given mass, are larger and more diffuse than their protoelliptical counterparts. The collapse of disks thus occurs through a relatively slow infall of baryons from ~10^2 kpc, and is halted by angular momentum. Infall from such distances is consistent both with the extent of dark haloes inferred from observations and with the high angular momenta of present-day disks ($\lambda\sim 0.4$)[85,86]. The location of galaxies in Fig. 3 is consistent with these ideas if the baryons in all galaxies collapsed in radius by roughly the same factor, about an order of magnitude, but less for late-type irregulars and more for early-type Es and spheroidal bulges.

It has been theorized that the Hubble sequence originates in the distribution of either the initial angular momenta[87,88] or else the initial densities[89] of protogalaxies. However, if overdensity and angular momentum are linked, with the high-σ fluctuations having lower λ, then these two apparently competitive theories become opposite sides of the same coin.

Consider finally the difference in Fig. 4 between the solid and dashed lines. The dashed lines, representing a lower-density Universe ($\Omega=0.2$), curve backward at the largest masses and lie far away from the circle representing the cores of the richest clusters, Abell classes 2 and 3. Because these regions of very high galaxy density contain at least several per cent of the mass in the Universe, the circle should lie between the 2 and 3σ lines (assuming gaussian statistics). It does so for the solid ($\Omega=1$) lines, but not for the dashed lines. At face value, this is evidence favouring an Einstein–de Sitter Universe for cold DM. However, there are at least two reasons why this argument should not be taken too seriously. First, the velocity dispersions represented by the Abell cluster circle in Fig. 4 correspond to the cluster cores. The model curves on the other hand refer to the entire virialized cluster, over which the velocity dispersion is considerably lower (as indicated schematically by the arrow attached to the circle in Fig. 4). Second, the assumption of spherical symmetry used in obtaining both sets of curves is only an approximation. The initial collapse is probably often quite anisotropic—more like a Zeldovich pancake than a sphere. It is, therefore, preferable to compare these data with N-body simulations than with the simple model represented by the curves in Fig. 4. Until this becomes possible we do not believe that the data in Fig. 4 allow a clear-cut discrimination between the $\Omega=0.2$ and $\Omega=1$ cases, especially if the Hubble parameter h is allowed to vary simultaneously within the observationally allowed range, as we have assumed.

Cosmological density

The most straightforward interpretation of the approximate constancy of $M/M_{\rm lum}\approx 10$ from galaxy through rich cluster scales (Fig. 1) is that dark matter clusters with galaxies. This is precisely what cold DM is expected to do. One then expects the density parameter $\Omega=(M/M_{\rm lum})\Omega_{\rm galaxies}\approx 10\times 0.02=0.2$, in agreement with $\Omega=0.2\times 1.5^{\pm 1}$ from the cosmic energy equation and the stability of clustering[90].

The value $\Omega\approx 0.2$ is consistent with all reliable measurements and furthermore gives an age for the Universe, t_0, consistent with globular cluster age estimates[91] ($\geq$15 Gyr) if $h\leq 0.6$. The observed abundance of deuterium plus helium-3 implies a lower limit[37] $\Omega_{\rm b}h^2\geq 0.01$, which is also consistent with $\Omega=0.2$ and $\Omega_{\rm b}\approx 0.02$ if $h\geq 0.7$.

Another argument favouring $\Omega=0.2$ for cold DM is based on preliminary N-body results[92], which indicate that superclusters and voids form on the observed scale for $\Omega=0.2$, but on too small a scale for $\Omega=1$ unless the Hubble constant is unrealistically small. However, this conclusion follows from comparing the N-body mass autocorrelation function $\xi_{\rm m}(r)$ with the observed galaxy autocorrelation function $\xi_{\rm g}(r)$. This is justified only if the galaxies are a good tracer of mass—if $M/L\approx$ constant. This is certainly not true for rich clusters, as illustrated in the top part of Fig. 1 and in Table 1, where M/L for very rich clusters is roughly six times larger than it is for small groups and for the Milky Way (including its DM halo). This means that some of the actual small-distance-mass autocorrelation is not included in the galaxy autocorrelation function; that $\xi_m(r)$ is steeper for $r \leq 1$ Mpc than $\xi_g(r)$. This effect is in the right direction to bring the $\Omega = 1$ N-body simulations into consistency with observations. Note that galaxy velocity dispersion averages also underestimate the actual mass-weighted velocity dispersion, because the high-velocity, dense regions of rich clusters are under-represented in the counts. This effect is also compatible with higher Ω.

The absence of measurable fluctuations in the cosmic microwave background also restricts Ω, because in a low-Ω Universe there is less growth of fluctuations both before and after recombination. The latest limits[38,39] on $\Delta T/T$ require $\Omega \geq 0.2h^{-4/3}$ (refs 93, 94), unless the Universe was reionized after recombination.

Both prejudice and the inflationary hypothesis favour the Einstein-de Sitter value $\Omega = 1$. (Actually, inflation implies more generally that $\Omega = 1 - \Lambda/3H^2$, where H is Hubble's constant and Λ is the cosmological constant[95], but we assume here that $\Lambda = 0$.) For $\Omega = 1$, $t_0 = 6.5h^{-1}$ Gyr, so consistency with globular cluster age estimates requires the Hubble constant to be perhaps unrealistically small. As we have discussed, the Zeldovich ($n = 1$) spectrum of primordial adiabatic fluctuations, which also follows from inflation, is compatible with models of galaxy formation in the cold DM scenario. Of course, the Zeldovich spectrum does not necessarily entail inflation. Moreover, inflation does not necessarily imply $\Omega = 1$: if there is a great deal of inflation, then, of course, Ω is very close to unity (assuming vanishing cosmological constant); but if we speculate that greater amounts of inflation are increasingly unlikely, then our horizon might happen to lie in a patch with $\Omega = 0.2$.

Could $\Omega = 1$ in the cold DM model? Based on Fig. 1, this could happen only if M/M_{lum} increases substantially on scales larger than rich clusters. Perhaps galaxy formation is suppressed in the voids, and the resulting luminosity contrast is so strong, for reasons we do not yet understand, that $M/L > 1{,}500$ there (see below). Alternatively, if the virial mass of clusters of galaxies is significantly underestimated, as suggested recently by Kaiser, and if galactic haloes extend much further than ~70 kpc, then the ratio M/M_{lum} may be substantially underestimated in Fig. 1, leading to a larger value for Ω. If galaxy formation is inefficient so that only large-overdensity perturbations can form galaxies—a possibility suggested by Fig. 4—the $\Omega = 1$, cold DM N-body simulations[92] can be brought into agreement with observations[96,97]. We conclude that a straightforward interpretation of the evidence summarized above favours $\Omega \approx 0.2$ in the cold DM picture, but that $\Omega = 1$ is not implausible.

Note that the cold DM model may require some means of suppressing galaxy formation in voids for $\Omega \approx 0.2$ as well as for $\Omega = 1$. This is required in the latter case to hide most of the mass. In a low-Ω Universe, on the other hand, large, very underdense regions cannot form by gravitation alone[98,99]; and galaxy formation must be suppressed somehow in regions of moderately low density if the density of galaxies in voids is less than one-quarter of the average density, the quoted upper limit for the Boötes void[100,101]. Suppression of galaxy formation may occur partly because of the substantial difference at $z < \Omega^{-1}$ between $\langle \rho \rangle$ and ρ_c in a low-density Universe.

Superclusters and voids

Recent, accurate redshift measurements of several thousand galaxies have revealed the presence of voids with linear dimensions ranging up to $\sim 50h^{-1}$ Mpc that are almost completely empty of bright galaxies. Most galaxies are concentrated in irregularly shaped, flattened, or elongated superclusters (see ref. 102 for fuller discussion and references). Two related observations are particularly interesting for their possible bearing on the origin of this large scale structure: a correlation of galaxy type with galaxy number density[103,104] and, possibly, a correlation between the orientation of cluster major axes and the direction to neighbouring clusters within $\sim 15h^{-1}$ Mpc (ref. 105).

In the hot DM picture, the fluctuation spectrum is rather sharply peaked at masses $\sim 4 \times 10^{15}$ (30 eV/m)^2. The suppression of smaller scale structure results in an essentially pressure-free collapse on the supercluster scale, with the formation of sharp caustics—Zeldovich pancakes[106,107]. If galaxies form only in the densest regions, where the shocked baryons have cooled sufficiently[108,109], most of the Universe would be essentially devoid of galaxies. Simulations[110] also show large-scale cluster orientation correlations resembling those observed. On the other hand, the rapid evolution of the autocorrelation function requires that the pancakes form at $z \leq 2$, which is uncomfortably recent if smaller structures including galaxies must form subsequently.

The cold DM scenario avoids this latter problem because galaxies and clusters would already have formed by the time of supercluster collapse. Would superclusters and voids arise in a cold DM Universe? There are good reasons to believe that pancakes, filaments, and voids would indeed form, and preliminary indications from N-body simulations suggest that they do[92,111]. The cold and hot DM fluctuation spectra are identical on the very largest scales, differing only in that the latter is cut off below $\sim 10^{15}$ $M_\odot$ by neutrino free streaming and normalized larger above this scale (see Fig. 2a). The presence of already-formed and partially-virialized substructure in the cold DM case causes supercluster collapse to be less dissipative than in the neutrino picture because the caustics are thickened and because a smaller fraction of the baryons remains as cold, uncondensed gas. Nevertheless, as Dekel[112] has shown, persistent flattened or elongated structures can form even in the absence of dissipation as a result of continued expansion in directions orthogonal to the collapse. Indeed, the sharp caustics and highly dissipative shocks in the neutrino picture may produce superclusters that are too flat compared with the observations, even when gravitational interactions with neighbouring superclusters are taken into account.

Another related difference between hot and cold DM is that the hot DM Universe is predicted to have a rather simple cellular structure while the cold DM Universe probably has a considerably richer structure, perhaps more like that observed. In particular, the sizes of superclusters and voids in the cold case should span a fairly broad range. This will be an important test of the models when enough galaxy redshift data become available to indicate the statistics of the void distribution.

What should one expect to find in the voids? In the hot DM picture, all galaxies form from the dense gas along the caustics. Hence, the centres of voids should be entirely empty of galaxies and should contain only low-density DM and hot primordial gas (heated by radiation from pancake shocks and too dilute to have cooled)[113]. In the cold DM picture, one might at first suppose that galaxies form more or less uniformly in space, with their density subsequently enhanced by gravitational clustering and the pancake distortion of the Hubble flow. One would then expect to find galaxies in the voids, although with lower density than in superclusters.

In a low-density Universe, both analytical calculations[98,99] and N-body simulations[92] suggest that large regions having $\rho/\langle \rho \rangle \leq 0.2$ cannot form by gravitational clustering alone. Nonetheless, large regions with few bright galaxies may actually be more likely in a low density cold DM Universe, for the following reason. On average, large galaxies form late when the average density has dropped well below the critical density. Larger initial fluctuations are thus required to form large galaxies in low-density regions. But larger fluctuations are statistically less likely in low-density regions with the flat, cold DM spectrum. This suppresses formation of large galaxies in moderate-size voids, and formation of clusters in larger voids[84].

In addition, feedback from nongravitational processes could amplify the number density contrast of bright galaxies compared with the underlying density of dark and baryonic matter. For example, at $z \sim 10$ the average density is highest where pancakes will later occur. This is where most of the earliest galaxies and rich clusters form, and these will be the regions earliest enriched in metals. Radiation from these early galaxies (and quasars, and possibly Population III stars or VMOs) could heat the gas in lower density regions, raising the Jeans mass, as discussed above, and suppressing small galaxy formation. Indeed, if this early radiation has a hard enough spectrum and heats the gas sufficiently rapidly, it could raise the gas temperature throughout the Universe to 10^6 K and essentially halt galaxy formation outside pancakes. One of us (M.J.R.) has recently discussed[114] processes for suppressing galaxy formation in protovoids. Finally, explosive shocks could also enhance galaxy formation in denser regions[115]. Although the efficacy of all these processes is uncertain and needs further investigation, we conclude that the existence of large regions in which the density of bright galaxies is low is probably not a serious problem for the cold DM picture.

Now let us briefly discuss the two types of correlations mentioned above. The observed correlation of galaxy type with galaxy number density[103,104] can, at least partly, be understood as a consequence of the greater statistical likelihood of large-σ fluctuations in regions of greater density (protoclusters), together with the effect discussed above that results in higher-σ fluctuations acquiring lower angular momenta on average and becoming elliptical galaxies or spheroidal bulges. There is also an environmental effect: lower-σ fluctuations yield dark haloes that are physically larger and more diffuse than higher-σ fluctuations. Disks, which form from such fluctuations, thus form slowly, by infall of gas from large radii within these extended haloes. Because large haloes have correspondingly large collision cross-sections, few disks can form in regions of high galaxy number density. In dense regions, the halo gas is stripped by collisions and is mixed with enriched gas from galactic winds to become the hot intergalactic medium observed in X rays. It will be interesting to investigate these effects with N-body simulations and a more detailed theory of galaxy formation.

Regarding the second type of correlation, Binggeli[105] has found that the position angles of nearby, elongated Abell clusters are within 45° of the direction to the nearest cluster, provided the two clusters are separated by $\leq 15h^{-1}$ Mpc. He found a similar, though less significant, correlation between the position angle of the brightest cluster galaxy's major axis and the direction to the nearest cluster. In the hot DM picture, where superclusters form before clusters and galaxies, such correlations arise naturally. Indeed an N-body simulation[110] has shown that such correlations also occur, but more weakly, even with a fluctuation spectrum having an adiabatic peak at $\sim 10^{15}\ M_\odot$ superimposed on an $n = 0$ spectrum, so that rich clusters and superclusters form almost simultaneously. However, a preliminary analysis[116] of cold DM N-body simulations finds Bingelli-type correlations only if $\Omega h \leq 0.2$.

It is important to find other observationally accessible information that can discriminate between cosmological models. The large-scale velocity fields of superclusters should be rather different in the hot and cold DM schemes because of the much greater dissipation in the former. With new instruments it will also be possible to study the $z < 2$ evolution of superclustering of quasars and of Lyα absorbing clouds, and perhaps the density and composition of the gas in voids.

It was once hoped that percolation analysis of the large scale galaxy distribution could help to distinguish between different cosmological models.[11,117]. However, when this analysis is applied to the CfA galaxy data, the results are found to be a sensitive function of the depth of the survey[118]. Moreover, realistic N-body simulations of isothermal and adiabatic scenarios (that is, with accurate treatment of gravitational interactions on small as well as large scales) have nearly identical percolation properties[110,119]. Better statistical tests are needed to compare objectively the large-scale distribution of matter in models and observations.

Conclusions

We have shown that a Universe with ~ 10 times as much cold dark matter as baryonic matter provides a remarkably good fit to the observed Universe. This model predicts roughly the observed mass range of galaxies, the dissipational nature of galaxy collapse, and the observed Faber-Jackson and Tully-Fisher relations. It also gives dissipationless galactic haloes and clusters. In addition, it may also provide natural explanations for galaxy-environment correlations and for the differences in angular momenta between ellipticals and spiral galaxies. Finally, the cold DM picture seems reasonably consistent with the observed large-scale clustering, including superclusters and voids. In short, it seems to be the best model available and merits close scrutiny and testing.

We thank Dick Bond, Jim Bardeen, Marc Davis, Avishai Dekel, George Efstathiou, Mike Fall, Carlos Frenk, Margaret Geller, Jim Gunn, Jim Peebles, Nicola Vittorio, and Simon White for valuable conversations. In addition, J.R.P. acknowledges the hospitality of the Max Planck Institute for Physics and Astrophysics, Munich during the summer 1983. This work was supported by the Department of Energy under contract no. DE-AC03-76SF00515 and by NSF grants AST-82-11551 and PHY-81-15541. This is Lick Observatory Contribution No. 436.

Ultrahigh gradient particle acceleration by intense laser-driven plasma density waves

C. Joshi*, W. B. Mori*, T. Katsouleas*, J. M. Dawson*,
J. M. Kindel† & D. W. Forslund†

* University of California Los Angeles, California 90024, USA
† Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA

Space-charge waves driven by resonantly beating two laser beams in a high-density plasma can produce ultrahigh electric fields that propagate with velocities close to c*. By phase-locking particles in such a wave, particles may be accelerated to very high energies within a very short distance.*

DURING the past four decades, we have witnessed an increase of six orders of magnitude in the output energy of high-energy accelerators, while the cost per MeV has been reduced by a factor of 16 per decade. But can this progress continue? Current accelerators, such as the Stanford linac, have accelerating fields of 200 keV cm^{-1}. However, for particle energies beyond 10 TeV, one had to invent schemes that can produce fields of at least 10 MeV cm^{-1}. In any particle accelerator scheme, the basic requirement for obtaining particles with ultrahigh energies is an intense longitudinal electric field that interacts with particles for a long time. Since highly relativistic particles move nearly at the speed of light c, the energy gained by the particles, $\int E \cdot dl$, is maximum if the field is made to propagate with the particles. Extremely large electric fields propagating with phase velocities close to c can be produced by space charge waves in a plasma (ionized gas). The maximum electric field that can be produced by such a wave is approximately $\sqrt{n_e}$ V cm^{-1}, where n_e is the plasma electron density per cm^3. Thus for plasma densities in the range 10^{16}–10^{20} electrons cm^{-3}, the longitudinal electric fields E_L, can be as large as 10^8–10^{10} V cm^{-1}. We now show that such high-gradient, high-phase velocity plasma density waves can be driven by intense laser beams. If particles could be phase-locked in such waves, this scheme has the potential for accelerating particles to ultrahigh energies in very short distances.

Theory

If an intense laser beam is propagated in a plasma, then in certain conditions, the transverse electric field of the laser (which may reach values of 10^9–10^{10} V cm^{-1}) can be very effectively transformed into a longitudinal electric field of a plasma density wave. In the laser accelerator scheme known as the 'Plasma beat wave accelerator' proposed by Tajima and Dawson[1,7], such a plasma wave can be driven by beating two colinear laser beams, with frequencies and wavenumbers (ω_0, k_0) and (ω_1, k_1), in a plasma resonantly, such that the frequency and the wavenumber of the plasma wave are

$$\begin{aligned}\omega_{\text{epw}} &= \omega_0 - \omega_1 \\ k_{\text{epw}} &= k_0 - k_1\end{aligned} \qquad (1)$$

To achieve the ultrahigh accelerating gradients, high-density plasmas ($10^{16} < n_e < 10^{20}\ \text{cm}^{-3}$) must be used. Also, because the laser of frequency ω_0 cannot penetrate a plasma whose density exceeds the critical density n_c, corresponding to the plasma frequency $\omega_P = \omega_0$, plasmas with densities less than the quarter critical density must be used. Physically, the plasma wave consists of regions of space charge, which propagate with a phase velocity v_{ph} that is equal to the group velocity of the beat wave $v_g = c(1 - \omega_p^2/\omega_0^2)^{(1/2)}$. These arise because the spatial intensity gradient of the beat wave envelope, which is in the direction of propagation, exerts a periodic force (ponderomotive force) on the plasma at wavenumber k_{epw}. The plasma wave is thus an electrostatic wave with $\mathbf{E}_{\text{epw}}$ parallel to $\mathbf{k}_{\text{epw}}$.

When two parallel propagating laser beams beat in a plasma resonantly, the plasma density fluctuations grow rapidly. Using fluid equations it can be shown that for $v_0/c \ll 1$, the plasma wave electric field, which is proportional to the perturbed density, initially grows in time with a growth rate

$$\delta = \left(\frac{1}{4}\frac{v_0(0)}{c}\frac{v_0(1)}{c}\omega_p\right) s^{-1} \qquad (2)$$

where $[v_0(0, 1)]/c = eE_{(0,1)}/m\omega_{(0,1)}c$ is the normalized oscillatory velocity of an electron in the laser field. Wavebreaking is approached when the perturbed density becomes as large as the initial density; however, to reach this limit the plasma wave must remain in phase with the beat wave. As the plasma wave grows, the relativistic effect on the frequency mismatch becomes important[2] and the plasma wave saturates at a lower amplitude given by

$$\varepsilon = \frac{eE_{\text{epw}}}{m\omega_{\text{epw}}c} = \left(\frac{16}{3}\frac{v_0(0)}{c}\frac{v_0(1)}{c}\right)^{1/3} \qquad (3)$$

Once the saturation amplitude is reached, the plasma wave amplitude actually begins to decrease, if this process alone acts to sustain the plasma wave[3].

As the plasma wave is an electrostatic wave, we can use Poisson's equation, $E_{\text{epw}} = 4\pi e n_e/k_{\text{epw}}$, to estimate the maximum electric field that we might expect if we assume that the perturbed electron density is equal to the initial density (the so-called cold plasma wavebreaking limit $\varepsilon = 1$). As the plasma wave is propagating at relativistic speed, the Lorentz transformation gives the maximum energy gained by an electron with initial energy $\gamma_{\text{ph}}mc^2$ as $2\gamma_{\text{ph}}^2 mc^2$ or (n_c/n_e) MeV in a distance $2\gamma_{\text{ph}}^2 c/\omega_p$. Here, $\gamma_{\text{ph}} = (\omega_0/\omega_p)$. For a given laser wavelength, the maximum energy gained increases as the plasma density is reduced but because the electric field scales as $\sqrt{n_e}$ it takes longer and longer to obtain this energy.

In a practical accelerator, we cannot use wavebreaking electric fields because as the electric field approaches this value it 'traps' background plasma electrons and begins to accelerate them. It also develops harmonics. Both of these effects are not desirable if we wish to accelerate an externally-injected bunch of electrons. Computer simulations (described below) show that a coherent plasma wave, without any significant number of self-trapped particles, can be generated with electric fields of the order of 10% of the wavebreaking electric field. If we require that the minimum value of the longitudinal field be 10 MeV cm^{-1}, this leads to a minimum plasma density of 10^{16} cm^{-3}. Using a CO_2 laser to excite a beat wave in such a plasma, gives maximum particle energies of ~100 MeV. The physical reason for this limit on the maximum energy is the dephasing of particles and the electric field of the correct polarity (which only exists for half-a-wavelength of the plasma wave in the wave frame). Although for a given plasma density the maximum energy scales inversely with square of the laser wavelength λ, it becomes increasingly difficult to keep the laser beam focused at shorter wavelengths because the Rayleigh length scales as λ. In a single stage, therefore, the best that can probably be achieved is to accelerate electrons to a few GeV using a laser with wavelength in the micrometre range.

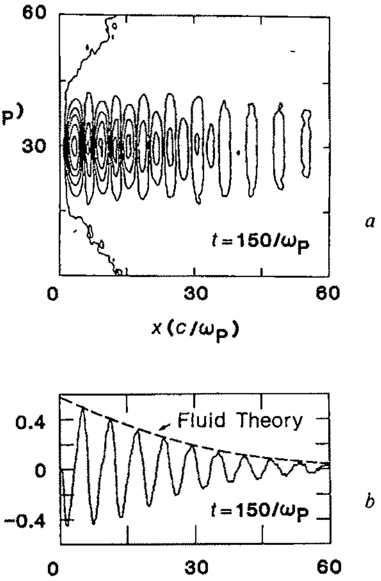

Fig. 1 Potential contours of the space-charge density wave driven by the two laser beams at time $150/\omega_p$ (*a*) section through the centre of the longitudinal electric field of the plasma wave (*b*). The dotted line in *b* shows a comparison of the rate of plasma wave build-up as predicted by the fluid theory with that obtained in these two-dimensional simulations.

To obtain higher energies, one has to be prepared for multistaging or invent a scheme for phase-locking the particles in the wave so that they do not out run the wave. One such scheme will be described later.

Simulations

Computer simulations were carried out using the two-dimensional fully relativistic, electromagnetic particle code WAVE[4] to study the above described acceleration mechanism in a self-consistent manner. A typical WAVE simulation has 10^6 electrons and 10^6 ions. From the particle positions and velocities, charge densities and current densities are found. Then Maxwell's equations are used to calculate the electric and magnetic fields or equivalently the forces on the particles. Equations of motion are used, to calculate new particle locations and velocities and then the process is repeated.

The results of a typical two-dimensional simulation are depicted in Figs 1-3. The parameters for this simulation were as follows: two laser beams $\omega_0 = 5\omega_p$ and $\omega_1 = 4\omega_p$, each with an r.m.s. intensity of $v_0 = 0.4\ c$, a transverse intensity profile of $\cos^2 y$ and a beam width of 30 c/ω_p were injected into a homogeneous plasma 60 c/ω_p long and 60 c/ω_p wide with a temperature of 2.5 keV. The laser beams had a cubic rise from zero to maximum intensity in $300/\omega_p$ after which the laser intensity remained constant. The ion-to-electron mass ratio was 1,836 and temperature ratio was 1. Thus for an IR laser with wavelengths 9.6 μm and 12 μm the parameters were: a hydrogen plasma with $n_e \sim 4.9 \times 10^{17}$ cm^{-3}, laser risetime ~7.6 ps, laser intensity ~2×10^{15} W cm^{-2}, beam width ~25 wavelengths and system length ~50 wavelengths. The simulation parameters were chosen to study both the beat wave driven plasma wave and other competing one- and two-dimensional effects.

The simulation results can be categorized into two time regimes. The first, during the risetime of the laser pulse when

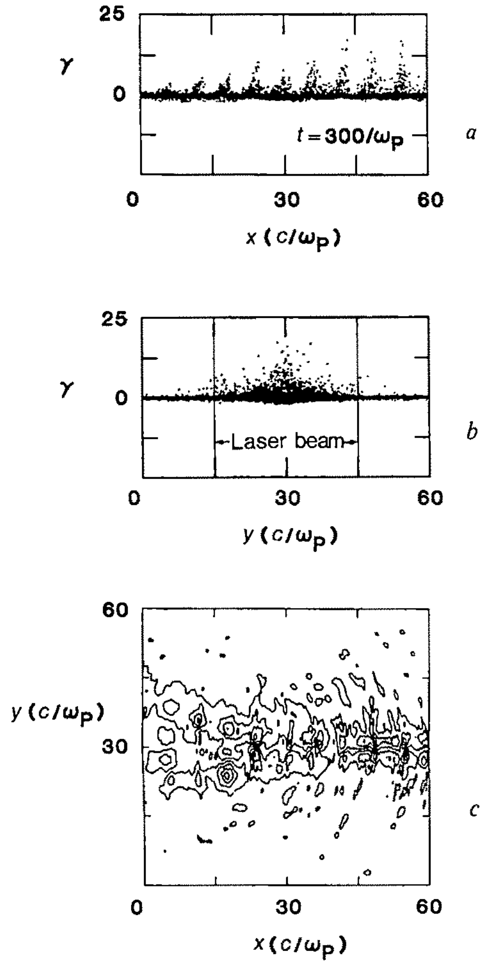

Fig. 2 Phase space plot (momentum in the x direction) of the plasma electrons shows that at time $300/\omega_p$, trapped electrons are accelerated in every wavelength of the plasma wave which represents an accelerating 'bucket' (*a*). Particles have larger energies on the right-hand side as they have seen an accelerating field for a longer time. The maximum particle energies of $\gamma = 25$ are in good agreement with theory. In the transverse direction, although the laser beam is 30 c/ω_p wide, most particles are confined to a narrow region down the centre of the accelerating wave (*b*). Contours of the self-consistent magnetic field at time $t = 300/\omega_p$ generated by the accelerating trapped particles (*c*). This field exerts a radial force on the trapped particles confining them in a small region down the axis and also forces the return current to flow on the outside of the region where it exists.

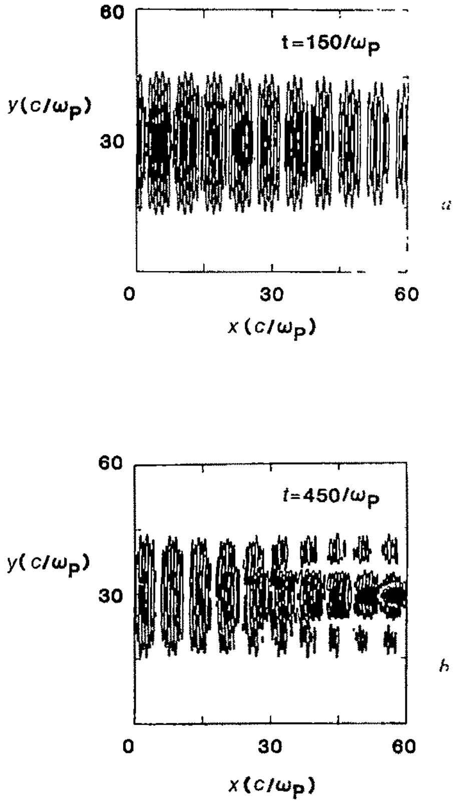

Fig. 3 Contour plot of the beat pattern produced by two colinearly-propagating laser beams in the plasma at time $150/\omega_p$ (*a*) and at $450/\omega_p$ (*b*). The x and y dimensions are in units of c/ω_p. Clear evidence for laser beam self-focusing is seen at the later time from the converging inner contours. As a result of self-focusing, the plasma is pushed out and the space-charge wave accelerating the particles disrupts.

a very coherent plasma wave grows and reaches saturation and the second after the peak of the laser pulse ($300/\omega_p$) when competing phenomena come into play.

Figure 1*a* shows the contour plot of the potential of the plasma density wave at $150/\omega_p$. According to the fluid theory, the plasma wave should reach peak amplitude at this time. The plasma wave wavefronts in the contour plot are seen to be planar. A section through the centre of the transverse axis of the longitudinal electric field plot is shown in Fig. 1*b*. An extremely coherent plasma wave builds up rapidly in time/space and saturates at $\varepsilon \simeq 0.5$, in excellent agreement with the value expected from the fluid theory. By $300/\omega_p$, the longitudinal electric field becomes non-planar as the laser beams begin to self-focus. Fluid theory would predict that one saturation is reached, the plasma wave amplitude decreases but simulations show that a 'plasma wave' with greatly reduced coherence persists driven by the multiple Raman forward scattering.

Figure 2*a* shows that the electrons trapped at an earlier time, when the plasma wave field was intense and coherent, have by time $300/\omega_p$ approached maximum energies. Accelerated particles leaving the right-hand boundary of the plasma (not shown here) have maximum energies of $\gamma = 25$, in reasonable agreement with theory. Here $\gamma = (1-\beta^2)^{-1/2}$ is the usual relativistic scaling factor. More important, however, is the fact that although the laser beam and, therefore, the plasma wave is 30 c/ω_p wide, most of the accelerated particles are collimated within 10 c/ω_p of the centre (Fig. 2*b*). The accelerating particles remain highly collimated because the trapped particles give rise to an azimuthal magnetic field which, in turn, exerts a radial force on the particles keeping them tightly focused. The contour plot of this self-generated magnetic field which can reach megagauss magnitudes is shown in Fig. 2*c*. The maximum field is in the regions where bunches of electrons are accelerated. The accelerated particles constitute a flow of charges or current which leaves the plasma positively charged, thus driving a return current of colder particles in the opposite direction. In the simulations the return current is found to flow predominantly on the outside of the region bounded by the self-generated magnetic field.

These two-dimensional simulations also allowed us to investigate competition between the beat wave driven plasma wave and Raman back- and side-scattering. To allow the growth of large angle side-scattering the transverse dimension of the beam was made periodic. Even in relatively cold plasmas ($T_e \sim$ 200 eV), where Landau damping is expected to be weak, Raman backscatter is not found to be a problem under two-frequency illumination. Small angle (from the forward direction) side-scatter can occur, effectively making the desired plasma wave non-planar. This gives rise to a radial component of the electric field; however, the self-generated magnetic field tends to keep the trapped particles focused in the centre of the plasma wave as discussed above.

Figure 3*a* shows the laser beat wave contours at $150/\omega_p$ as the beams propagate from left to right. Contrast this with laser

Fig. 4 In the phase stabilization scheme, Surfatron, a perpendicular magnetic field is applied to the wavevector of the longitudinal space-charge wave. In the wave frame, a trapped particle comes to an equilibrium position against the side of the potential well where the 'trapping' and 'de-trapping' forces balance: $E_0 \sin k'_{epw} x' = \gamma_{ph}B$. The energy gained by the particle in the direction of the wave is simply $\gamma_{ph}Bx$.

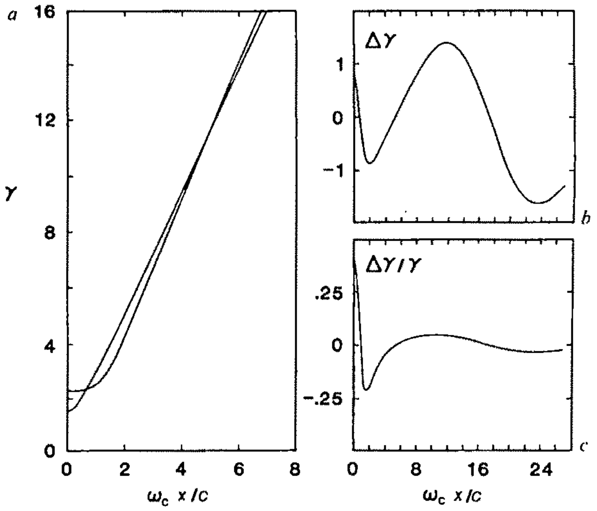

Fig. 5 *a*, Energy gain (γ) plotted against distance for two Surfatron particles of different initial velocities ($0.8c$ and $0.9c$). In *b*, energy separation ($\Delta\gamma$) of the particles remains roughly constant, while in *c*, $\Delta\gamma/\gamma$ decreases rapidly. $V_{ph}/c = .9$, $cE/B = 2.5$, $\omega/\omega_c = 9$. ω_c is the nonrelativistic electron cyclotron frequency.

beam contours at $450/\omega_p$ (Fig. 3*b*). Although the outer contours are still the same size, the contours at the beam centre are seen to 'self-focus' to a smaller size. We have determined that this self-focusing is due to two effects: intensity-dependent refractive index (relativistic self-focusing) and transverse intensity gradient (ponderomotive self-focusing). Whether the beam self-focuses as a whole or breaks up into smaller filaments depends on the transverse size and the intensity profile of the laser beams. In any case, catastrophic self-focusing is an undesirable phenomenon because it tends to push the plasma out and create a channel of low density, thereby destroying the resonance condition for driving the plasma wave and terminating the accelerating process.

Two-dimensional simulations of the beat wave build-up have been encouraging and given results that are consistent with predictions of the fluid and single particle theories. Although there are many competing instabilities in the plasma, these occur on a longer time scale; and plasma wave coherence can be maintained over typically tens of plasma wave wavelengths at the front of the laser pulse, which continually moves into unperturbed plasma. If the laser pulse is longer than this, then wave-particle and wave-wave interactions heat up the plasma to temperatures of hundreds of keV at the back of the laser pulse and make it extremely turbulent. Thus, extremely short laser pulses on the order of a few picoseconds are probably most effective in this acceleration scheme. Such short pulses will also inhibit other instabilities such as the stimulated Brillouin scattering.

Phase-stabilization

The limit on energy gain of a particle in the Plasma beat wave accelerator can be overcome if a magnetic field of appropriate strength, $\gamma_{ph}B < E_{epw}$, is applied perpendicular to the plasma wave (Fig. 4). This accelerates particles parallel to the phase fronts of the accelerating wave, which, in turn, provides a force keeping the particles in phase with the wave[5]. In principle, therefore, particles can gain energy at rate

$$\frac{\Delta U}{\Delta x} = 0.1\left[\frac{B_{KG}}{n_{16}\lambda_\mu}\right](n_{16})^{1/2}\ \mathrm{GeV\,cm^{-1}} \qquad (4)$$

in the direction of the wave and the accelerated particles move at an angle $\tan\theta = 3\times10^{-3}\sqrt{n_{16}\lambda_\mu}$ with respect to the wavevector of the plasma wave. Here B_{KG} is the applied magnetic field in kilogauss, n_{16} is the plasma density in units of $10^{16}\ \mathrm{cm^{-3}}$ and λ_μ is the laser wavelength in micrometres. The quantity in the square bracket must be $<\varepsilon$ to prevent the detrapping by the magnetic field. Because the particles move at an angle with respect to the plasma wave, the width of the plasma wave necessary to accelerate the particles to the desired energy can be rather large. Fortunately, the plasma wave width (and hence the energy required to excite it) can be reduced considerably by beating the electromagnetic waves at a finite angle (optical mixing) rather than colinearly[6]. One possible limitation associated with finite angle optical mixing is that, while the particles move at $\sim c$, the laser energy propagates through the plasma with the particles at v_g. In a device of length L the particles move ahead with respect to the laser pulse by a distance $\Delta L = \omega_p^2 L/\omega_0^2$. Thus the plasma wave coherence must be maintained over a distance ΔL behind the leading edge of the laser pulse. We have carried out one-dimensional (one spatial, three velocites) particle simulations, which confirm the above scaling laws. Two-dimensional computer simulations are being carried out to test the phase-locking and cross-field acceleration concept when the plasma wave is driven by finite angle optical mixing, but this technique has the promise of utilizing the high gradients of space-charge plasma waves for obtaining ultrahigh energies. For example, using a 100-kG magnetic field across a $10^{19}\ \mathrm{cm^{-3}}$ plasma and a 1-μm laser, particles may be accelerated to 100 GeV in a device that is only 3.16 m long.

Laser and plasma requirements

While there is a tremendous promise for $>10\ \mathrm{MeV\,cm^{-1}}$ acceleration gradients in this scheme, there are technological obstacles between the concept and a realizable working system. The laser needed for a TeV class accelerator based on this concept will exceed the capability of fusion lasers (presently the largest laser systems) in the areas of peak power, pulse width, repetition rate, and the need for the power to be delivered in a single diffraction limited beam. Considerable work is also needed in the areas of focusing and optical transport of such high peak power leaser beams.

An estimate of the laser power required can be obtained from energy balance arguments. The longitudinal electric field of the plasma wave represents an energy density

$$W_{epw} = \frac{E_{epw}^2}{8\pi} \simeq 500\, n_{16}\varepsilon^2\ \mathrm{J\,cm^{-3}} \qquad (5)$$

Because the group velocity of the plasma wave, $3v_e^2/v_{ph} \ll c$, we assume that the laser pulse excites the plasma wave only in the volume through which it propagates. To avoid significant pump depletion, the total energy in the laser beams must be much greater than that in the plasma wave.

The problem of producing plasmas (particularly with a cross magnetic field) with densities between $10^{16} < n_e < 10^{20}$ cm^{-3} and with the required length and homogeneity will also require considerable attention. At high intensities that are necessary in this scheme, the requirement that plasma frequency be exactly equal to the difference frequency may be relaxed, but this issue needs careful investigation.

Prospects for ultrahigh energies

High-phase velocity space charge waves in a plasma have the potential for producing the high accelerating gradients that are necessary for a new generation of particle accelerators. Whether this scheme can be used to accelerate particles to ultrahigh energies depends on how well the phase stabilization (Surfatron) scheme can be made to work in practice. Particular problems are pump depletion, filamentation of the laser and injected particle beams, and the effect of self-generated magnetic fields on the accelerating particles.

On the positive side, the Surfatron scheme would produce a compact accelerator with a high quality beam. The energy spread, $\Delta\gamma/\gamma$ would be small because approximately half of the injected particles quickly form accelerating 'buckets' that are narrow in phase space near the equilibrium point. In the wave frame this is where $\gamma_{\mathrm{ph}}B$ is equal to the local longitudinal electric field. Thus all the particles gain energy at nearly the same rate, the one given by equation (4). The bunch length of the final beam as well as $\Delta\gamma/\gamma$ is thus expected to be extremely small, as shown in Fig. 5.

The number of accelerated particles N can be estimated from the consideration of the energy balance[6]:

$$N = 2\times10^{10}\frac{\text{laser energy (kJ)}}{\text{particle energy (GeV)}}\,\varepsilon\alpha\lambda_{\mu}\, n_{16} \qquad (6)$$

where factor α is the ratio of particle energy to wave energy.

The zero-order motion of the particles in the Surfatron scheme is approximately a straight line, and thus synchrotron radiation loss turns out not be to be a problem. The radiation loss due to high-order bounce motion[5] and due to oscillation in the laser field, as well as other loss mechanisms such as Coulomb scattering and bremsstrahlung radiation, are also not thought to be serious problems.

Finally, the acceleration scheme is still at an embryonic stage for a reliable estimate to be made of its potential total efficiency from wall power (ac) to beam power. The severest limitation, one that is common to all laser acceleration schemes, is the a.c.-to-laser beam efficiency. If we optimistically assume this to be 10% then using our simulations as a guide we may be able to achieve a total efficiency between 10^{-3} and 10^{-4}.

Much of our information on climatic evolution during the past million years comes from the time series describing the isotope record of deep-sea cores. A major task of climatology is to identify, from this apparently limited amount of information, the essential features of climate viewed as a dynamic system. Using the theory of nonlinear dynamic systems we show how certain key properties of climate can be determined solely from time series data.

EXPERIMENTAL data have essentially two roles in the process of modelling. First, they parameterize the equations postulated by the modeller. Second, they set constraints to be satisfied by the model. For instance, a reasonable model of Quaternary glaciations should reproduce the general aspects of a palaeotemperature time series as deduced from ice or deep-sea core data and, in particular, should exhibit the characteristic time scales of 100,000, 41,000 and 22,000 yr (ref. 1). In either case, however, the information drawn from the data will remain esentially one-dimensional. Thus, starting from the time series of a certain variable one may construct a power spectrum or a histogram which, despite their interest, do not provide any hint about the additional variables that may affect the evolution. We show here that experimental data contain far richer information which, independent of any particular model, can be used to 'resurrect' the multivariable dynamics of a system starting from a time series pertaining to a single variable.

We should first comment on the status of a time series from the standpoint of the theory of dynamical systems. Let $X_0(t)$ be the time series available from the data, and $\{X_k(t)\}$, where $k=0, 1, \ldots n-1$, the full set of variables actually taking part in the dynamics. $\{X_k\}$ is expected to satisfy a set of first-order nonlinear equations, whose form is generally unknown but which, given a set of initial data $\{X_k(0)\}$, will produce the full details of the system's evolution. It is instructive to visualize this evolution in an abstract multi-dimensional space spanned by these variables, the phase space. An instantaneous state of the system becomes a point, say P, in this space, whereas a sequence of such states followed as time varies defines a curve, the phase space trajectory (see Fig. 1). As time grows and transients die out, the system is expected to reach a state of permanent regime, not necessarily time-independent. In phase space, this will be reflected by the convergence of whole families of phase trajectories towards a subset of phase space (C in Fig. 1), such that the system subsequently remains trapped therein. We refer to this invariant set as the attractor.

The interest of the phase space description of a system lies primarily in the fact that the nature of the attractors provides extensive information on the time behaviour of the variables and on the nature of their coupling. For instance, a point

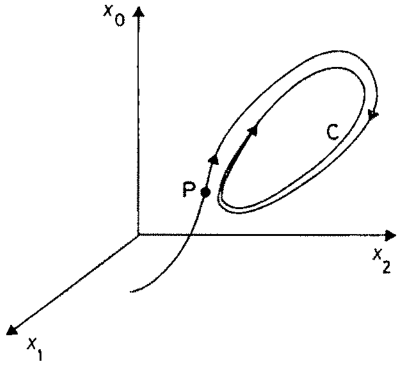

Fig. 1 Typical phase space trajectory emanating from point P and converging to a periodic attractor, represented by curve C.

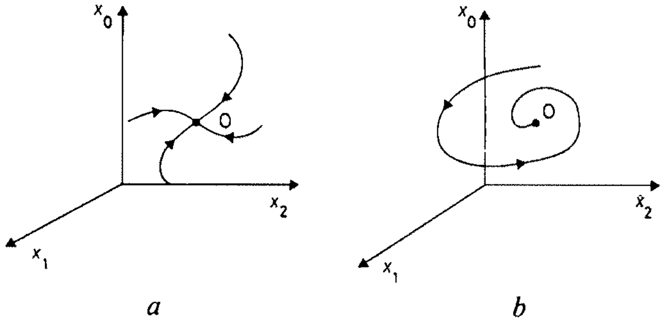

Fig. 2 Two different approaches to a steady state, represented by point 0 in phase space (point attractor). *a*, Monotonic approach; *b*, approach through damped oscillations.

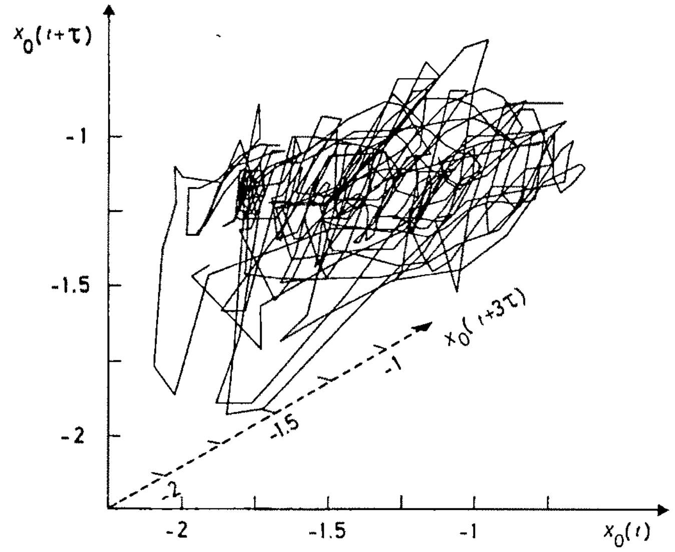

Fig. 3 A view of the climatic attractor embedded in a three-dimensional phase space. The result utilizes about 500 equidistant values of X_0. These are inferred from the oxygen isotope record obtained from the V28-238 deep sea core of Shackleton and Opdyke[4] and extended over the past million years, following an interpolation available from the data bank of the University of Louvain[7]. The value of the shift τ adopted in drawing the figure is $\tau = 2$ kyr.

attractor (point 0 in Fig. 2*a*, *b*) implies that the transient-free behaviour of the system will be time-independent. In addition, if the attractor is approached in the way shown in Fig. 2*a* the transients will die out monotonically, whereas a spiral approach like that in Fig. 2*b* indicates that transients perform damped oscillations. An attractor in the form of a closed curve (C in Fig. 1) implies, on the other hand, that the system will perform sustained oscillations in time with an intrinsically-determined period and amplitude. Finally, multiperiodic motions with incommensurate frequencies are represented in phase space by high-dimensional attracting toroidal surfaces. In each of the above cases, the character of the attractor also gives an indication of the minimum number of variables that should be involved in the description. Thus, for the zero-dimensional attractors of Fig. 2 ($d = 0$) we need, respectively, at least one variable ($n = 1$) for Fig. 2*a* and two variables ($n = 2$) for Fig. 2*b*. For the one-dimensional attractor of Fig. 1 ($d = 1$) we need at least two variables ($n = 2$), and for the simplest quasi-periodic phenomenon we need at least a two-dimensional torus ($d = 2$) embedded in a three-dimensional phase space ($n = 3$).

So far we have argued in terms of attractors which are points, lines or surfaces or, in more technical terms, smooth topological manifolds characterized by an integer dimensionality. In recent years, it has been firmly established that geometrical objects exist which are not topological manifolds. Such constructions, which have a non-integer dimensionality, are known as fractals[2]. The theory of dynamical systems and some experimental results from fluid dynamics and chemical kinetics provide us with many examples of fractal attractors[3]. The importance of the latter stems from the fact that they model irregular, time-dependent phenomena, characterized by two features, both of which are shared by the climatic system: a marked sensitivity to initial conditions; and the appearance of large dispersions from a mean motion similar to a stochastic process, even though the underlying dynamics is perfectly deterministic. Note that the dimensionality of an attractor, fractal or smooth, is bound to be a number smaller than the number of variables present in the evolution.

Climatic attractor

We shall establish the existence of an attractor associated with the long-term climatic evolution of the past million years and determine its dimensionalty. Knowing the characteristics of this climatic attractor automatically gives us information on the minimum number of variables that must be introduced into the description.

Our starting point is the oxygen isotope record obtained from the equatorial Pacific deep-sea core V28–238 (refs 4, 5), which is one of the best climatic records available, because the sediment accumulated at a fairly regular rate[6].

Let $X_0(t)$ be the corresponding time series[7]. Because the n variables $\{X_k(t)\}$ satisfy a set of first-order differential equations, successive differentiation in time reduces the problem to a single (generally highly nonlinear) differential equation of nth order for one of these variables. Thus, instead of $X_k(t)$, $k = 0, 1, \ldots, n-1$, we may consider $X_0(t)$, the variable supplied by the time series data, and its $n-1$ successive derivatives $X_0^{(k)}(t)$, $k = 1, \ldots, n-1$, to be the n variables of the problem spanning the phase space of the system[8]. Now, both X_0 and its derivatives can be deduced from the single time series pertaining to $X_0(t)$, as provided by the data. We see, therefore, that, in principle we have sufficient information at our disposal to go beyond the one-dimensional space of the original time series and to unfold the system's dynamics into a multidimensional phase space.

Actually, as suggested originally by Ruelle[9], instead of $X_0(t)$ and $X_0^{(k)}(t)$ it will be easier to work with $X_0(t)$, and the set of variables obtained from it, by shifting its values by a fixed lag τ. We, therefore, consider from now on the phase space defined by the variables :

$$X_0(t), X_0(t+\tau), \ldots, X_0(t+(n-1)\tau) \qquad (1)$$

For a typical choice of τ these variables are expected to be linearly independent, and this is all one needs to define properly a phase space. A simple example illustrating how an unshifted function can give rise to a linearly independent one by a simple shift is provided by the polynomials $X_0(t) = t^2$, $X_0(t+\tau) = t^2 + 2t\tau + \tau^2$. These two functions are indeed independent, as

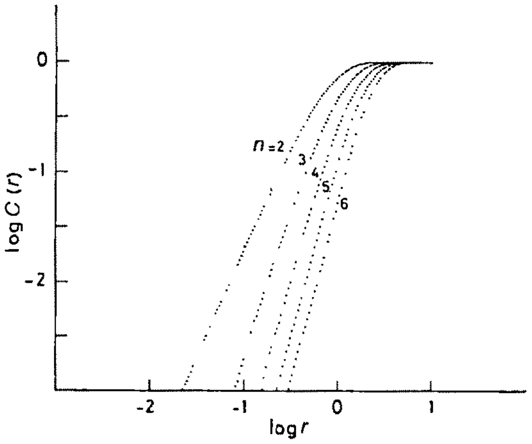

Fig. 4 Distance dependence of the correlation function on the climatic attractor. Note the existence of an extensive range of linearity, from which the dimensionality of the attractor can be inferred. Parameter values as in Fig. 3, except that $\tau = 8$ kyr.

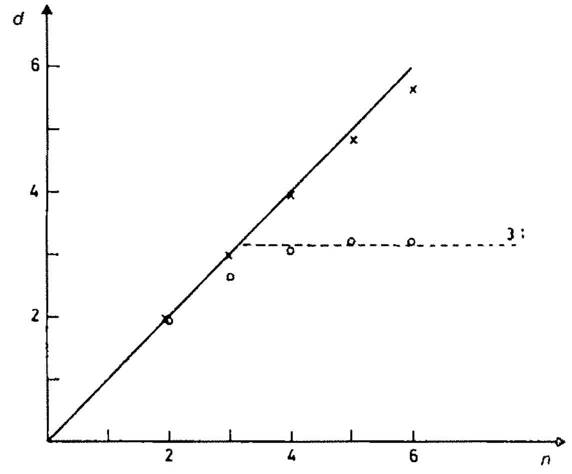

Fig. 5 Dependence of dimensionality, d on the number of phase space variables, n for the climatic attractor (O) and for a white noise signal (×) for the same parameters as in Fig. 4. Notice the saturation to a plateau value of ~3.1 in the first case, and the $d \sim n$ relationship in the second case.

the second polynomial contains terms of first and zero degree in t, which are absent in the first one.

Before describing the procedure that will enable us to obtain quantitative information on the nature of the climatic attractor and, in particular, on its dimensionality we present, in Fig. 3, a characteristic view of this object in a three-dimensional phase space. This view clearly exhibits the complexity of the underlying motion. However, the data are too coarse to draw any conclusion from this figure alone. It will be our task to characterize the complexity of the dynamics more sharply and, in particular, to assess its similarities and differences with random noise. Note that similar phase portraits have been constructed from experimental data pertaining to chemical kinetics[10].

Analytical procedure

We now describe briefly a recently proposed procedure[11,12] which allows the indentification of some salient features of the phase space portrait of a dynamical system. Consider a set of N points on an attractor embedded in a phase space of n dimensions, obtained from a time series:

$$\begin{aligned}&X_0(t_1), \ldots, X_0(t_N)\\ &X_0(t_1+\tau), \ldots, X_0(t_N+\tau)\\ &\vdots\\ &X_0(t_1+(n-1)\tau), \ldots, X_0(t_N+(n-1)\tau)\end{aligned} \tag{2}$$

For convenience we introduce a vector notation: $\mathbf{X}_i$ which stands for a point of phase space whose coordinates are $\{X_0(t_i), \ldots, X_0(t_i+(n-1)\tau)\}$.

A reference point $\mathbf{X}_i$ from these data is now chosen and all its distances $|\mathbf{X}_i - \mathbf{X}_j|$ from the $N-1$ remaining points are computed. This allows us to count the data points that are within a prescribed distance, r from point $\mathbf{X}_i$. Repeating the process for all values of i, one arrives at the quantity

$$C(r) = \frac{1}{N^2} \sum_{\substack{i,j=1\\ i\neq j}}^{N} \theta(r - |\mathbf{X}_i - \mathbf{X}_j|) \tag{3}$$

where θ is the Heaviside function, $\theta(x) = 0$ if $x < 0$, $\theta(x) = 1$ if $x > 0$. The non-vanishing of this quantity measures the extent to which the presence of a data point $\mathbf{X}_i$ affects the position of the other points. $C(r)$ may thus be referred to as the (integral) correlation function of the attractor.

Suppose that we fix a given small parameter ε and we use it to define the site of a lattice which approximates the attractor. If the latter is a line, the number of data points within a distance r from a prescribed point should be proportional to r/ε. If it is a surface, this number should be proportional to $(r/\varepsilon)^2$ and, more generally, if it is a d-dimensional manifold it should be proportional to $(r/\varepsilon)^d$. We expect, therefore, that for r, relatively small $C(r)$ should vary as

$$C(r) = r^d \tag{4}$$

In other words, the dimensionality d of the attractor is given by the slope of the log $C(r)$ versus log r in a certain range of values of r:

$$\log C(r) = d|\log r| \tag{5}$$

This property remains valid for attractors of fractal dimensionality.

The above results suggest the following algorithm (a similar procedure has also been proposed in the context of fluid dynamics[13,14]):

(1) Starting from a time series, we can construct the correlation function, equation (3), by considering successively higher values of the dimensionality n of phase space.

(2) Deduce the slope d near the origin according to equation (5) and see how the result changes as n is increased.

(3) If d reaches a saturation limit beyond some relatively small n, the system represented by the time series should possess an attractor. The saturation value d_s will be regarded as the dimensionality of the attractor. The value of n beyond which saturation is observed will provide the minimum number of variables necessary to model the behaviour represented by the attractor.

Application to climatic data

This procedure has been applied to the analysis of the data pertaining to core V28–238. Figure 4 gives the dependence of log $C(r)$ versus log r for $n = 2$ to $n = 6$. We see that there is indeed an extended region over which this dependence is linear, in accordance with equation (5). Figure 5 (points in circles) shows that the slope reaches a saturation value at $n = 4$, which is about $d_s = 3.1$. The same plot also shows the way in which d varies with n if the signal considered is a Gaussian white noise: there is no tendency to saturate. In fact, in this case d turns out to be equal to n. It should be emphasized that the above results are independent of the choice of the time lag τ, provided that the latter is of the order of magnitude of the times scales pertaining to the long-term climatic evolution, and the linear independence of the variables is secured.

The existence of a climatic attractor of low dimensionality shows that the main feature of long-term climatic evolution may be viewed as the manifestation of a deterministic dynamics, involving a limited number of key variables. The fact that the attractor has a fractal dimensionality provides a natural explanation of the intrinsic variability of the climatic system, despite its deterministic character[15]. Moreoever, it suggests that despite the pronounced peaks of spectra in the frequencies of the orbital forcings, the actual behaviour is highly non periodic[16]. A new interpretation of variance spectra of the ice volume record is, therefore, necessary.

Conclusion

We have identified a number of intrinsic properties of the climate assuming it to be dynamical system, using only the time series obtained from the data.

Our results do not anticipate the validity of any particular model of climatic evolution. Rather, they set a number of constraints that should be satisfied by a model. In particular, they suggest that models involving four variables could already provide a description of the salient features of the system.

Our approach could be applied to many other problems in which naturally occurring complex systems are probed through time series. Within the context of atmospheric physics and climatotology, one important example is the blocking transition. Another promising field of application are biological rhythms like the heart beat or the electroencephalogram[17]. In the long run, it may be hoped that fractal dimensionality could become for such systems a useful characterization of their specificity as well as a measure of their complexity.

We thank P. Pestiaux for providing the time series of the V28-238 core and P. Bergé for an enlightening discussion. The work of C.N. is supported, in part, by the EEC under contract no. STI-004-J-C(CD).

Structure of the nucleosome core particle at 7 Å resolution

T. J. Richmond, J. T. Finch, B. Rushton, D. Rhodes & A. Klug

MRC Laboratory of Molecular Biology, University Postgraduate Medical School, Hills Road, Cambridge CB2 2QH, UK

The crystal structure of the nucleosome core particle has been solved to 7 Å resolution. The right-handed B-DNA superhelix on the outside contains several sharp bends and makes numerous interactions with the histone octamer within. The central turn of superhelix and H3 · H4 tetramer have dyad symmetry, but the H2A · H2B dimers show departures due to interparticle associations.

THE nucleosome is the primary repeating unit of DNA organization in chromatin[1-3]. Extensive digestion of chromatin with micrococcal nuclease releases the nucleosome core, a small, well-defined particle which has been crystallized. The particle mass (~206 kilodaltons) is equally distributed between 146(±2) base pairs (bp) of DNA and an octamer formed by two each of the histone proteins, H2A, H2B, H3 and H4 (the outer histone H1 and the linker DNA having been removed during nuclease digestion[4]). The crystals first obtained were of limited order and gave a picture of the particle to 20 Å resolution[5]. We later prepared better crystals which diffracted to about 5 Å, having a single particle in the asymmetric unit[6]. We describe here the three-dimensional structure of the nucleosome core particle at 7 Å resolution determined by X-ray diffraction and multiple isomorphous replacement. This advance was achieved by improved diffractometry, control of the crystal unit cell parameters by adjustment of hydration, and derivatives prepared from multi-heavy atom cluster compounds.

The nucleosome core crystals have previously been investigated by several structural methods. Electron microscopy and X-ray diffraction techniques were initially used to obtain electron density maps in the principal projections, suggesting that the particle had the shape of a disk 57 Å thick and 110 Å in diameter. The DNA appeared to be wound around the histone core in 1.8 turns of a flat superhelix with a pitch of 28 Å[5]. Using neutron diffraction in conjunction with contrast matching[7,8], the DNA and protein components were seen as separate densities in projections at 25 Å resolution. The three-dimensional shape of the octamer alone was determined to a resolution of 20 Å by image reconstruction from electron micrographs of negatively stained, ordered aggregates[9]. The assignment of histone locations on the resulting low-resolution map relied on DNA–histone[10,11] and histone–histone (for references, see ref. 12) proximities obtained from chemical cross-linking experiments, and the neutron experiments fixed the orientation of the DNA superhelix on the octamer. The suggested division of the octamer into two H2A · H2B dimers residing on opposite faces of a H3 · H4 tetramer agrees well with the pattern of dissociation found in earlier physicochemical studies[13,14]. The tetramer (proteolysed) and octamer have also been crystallized in the absence of DNA, but structures have not yet been reported[15,16].

The electron density map at the higher resolution of 7 Å described here reveals many new structural features. The DNA is not bent uniformly into the superhelix, but exhibits several regions of tight bending or possible kinking, adjacent to points of substantial contact with histones H3 and H4. The histone–DNA interactions occur on the inside of the superhelix; the protein density does not seem to embrace the outside of the

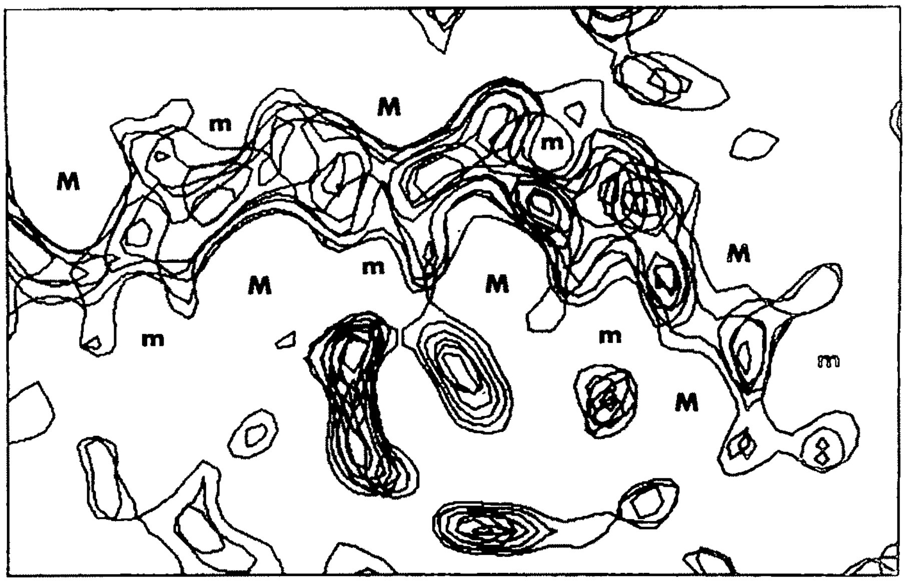

Fig. 1 Electron density of an arc of the DNA superhelix, showing two turns of the double helix. Alternating major (M) and minor (m) grooves are indicated. Three sections (−10 to −12) of the map, 1.73 Å apart, were stacked to show a slice through the double helix. The density seen below the arc of DNA is part of H2B[1].

DNA nor protrude between the turns of the superhelix. Protein domains are now visible, consistent with the earlier histone assignments, and the location of histone H3 has been confirmed by a heavy atom label. Non-crystallographic dyad symmetry relates the halves of the H3·H4 tetramer and the central turn of DNA superhelix; the dyad symmetry, however, does not extend to the same degree to the two H2·H2B dimers, due to interactions between adjacent particles in the crystal.

X-ray analysis and map interpretation

Nucleosome cores from beef kidney were prepared and crystallized as described previously[6]. The space group is $P2_12_12_1$, with one particle of 206,000 daltons per asymmetric unit. The unit cell dimensions of the crystals are dependent on the mean length of the core DNA in a particular preparation[6,17]. The *b*-axis dimension shows the greatest variability, about 4 Å per base-pair increment. The cell dimensions also depend on the degree of hydration, and we found that the crystalline order was increased by shrinkage to an essentially stable optimum state. Thus in 20% 1,6-hexanediol, the *b*-axis length decreases from 200 Å to 184 Å, and the order increases by about 1 Å in resolution in all directions, although the fall-off in intensity remains anisotropic. As a test for particle integrity, DNase I digestion was carried out in the presence of hexanediol, and the positions and frequencies of cutting were found to be unaffected except for minor deviations near the ends of the DNA. Naked DNA would be unwound by about 3% in screw angle at the alcohol concentrations used here[18]. No change in the high angle X-ray pattern[6] characteristic of B-form DNA was detected.

A variation of ±1.5% in the *b*-cell dimensions between different crystals was compensated by adjusting the alcohol concentrations over the range 21–27% to systematically obtain cell dimensions of $a = 107.5$, $b = 184$, $c = 110.5$ Å. The crystal was mounted in a solution containing low gelling temperature agarose which set on cooling to maintain constant hydration during data collection at 4 °C and to keep it fixed in position. The glass capillaries were gently tapered at one end to provide a good fit to the rod-shaped crystals, thereby minimizing X-ray absorption; this was less overall in this method than in conventional mounting techniques, and resulted in a deviation of typically ±5% about the capillary axis.

X-ray diffraction data were collected with a modified four-circle, Hilger–Watts diffractometer mounted on an Elliot rotating anode GX13 X-ray source, using well collimated beams to ensure accurate data at low resolution. For each dataset, the 3,800 reflections from 35 Å to 7 Å and their Friedel mates were measured twice using a partial peak scan method followed by profile fitting analysis to yield the integrated intensities (T.J.R., in preparation). In total, 64 crystals were used for the three datasets. The merging *R*-factors for the amplitudes were 0.05–0.06 over all crystals and symmetry equivalents for a dataset. A crystal was abandoned after one of several reference reflections had decayed by 20% of its initial intensity.

Two heavy atom derivatives were used to determine the phases by the method of multiple isomorphous replacement. Cluster compounds containing several heavy atoms were used in order to overcome the difficulties imposed by the large asymmetric unit and fall-off in the diffraction intensity. The first was tetrakis(acetoxymercuri)methane (TAMM)[19] used at 2 mM and solubilized in 20 mM glycylglycine. TAMM bound to essentially a single site as determined from difference Patterson projections. The second heavy atom cluster, di-μ-iodo, bis(diaminoethyl-*N*,*N*′)diplatinum(II) (PIP) was used at 0.1 mM and found to bind at three major and several minor sites which were located by difference Fourier projections using the phases generated from the TAMM derivative. The *R*-factors for the scaling of the TAMM and PIP datasets to the native dataset were 0.12 and 0.17, respectively. The heavy atom parameters were refined against the centric data using the F_{hle} procedure[20], and resulted in phasing power factors, f_H/E, for the two derivatives of 1.55 and 1.72, respectively (f_H is the r.m.s. calculated heavy atom contribution to the structure factor, and E is the r.m.s. closure error). The figures of merit over all the data were 0.543 for the selected enantiomorph and 0.529 for the opposite hand.

The major and minor grooves of the DNA (or conversely the phosphodiester backbones) are clearly visible as alternating cusps in the electron density map over all the expected length of the DNA, thus defining the DNA superhelix (Fig. 1). Several rods of strong density (presumably α-helices) are seen on the inside of the DNA superhelix, each belonging to discrete regions of electron density, which appear to define the histone domains in a manner consistent with the assignments deduced from the low-resolution map[9] and chemical cross-linking data[10–12]. Thus the order of the main histone contacts from end to end of the DNA superhelix is: H2A, H2B, H4, H3, H3, H4, H2B, H2A. The density at the interfaces between histones cannot, however, be assigned unambiguously at this resolution, and we have ignored any dovetailing that might exist, particularly between H3 and H4. The particle dyad axis (see below) was determined by comparing prominent features in the histone tetramer and the grooves of the central turn of the DNA superhelix.

As a check on the assignments, the volumes of the DNA and of the individual histone domains were estimated by summing the relevant contour areas over all sections. The fractional volume of the crystal occupied by the core particle is 0.35 as

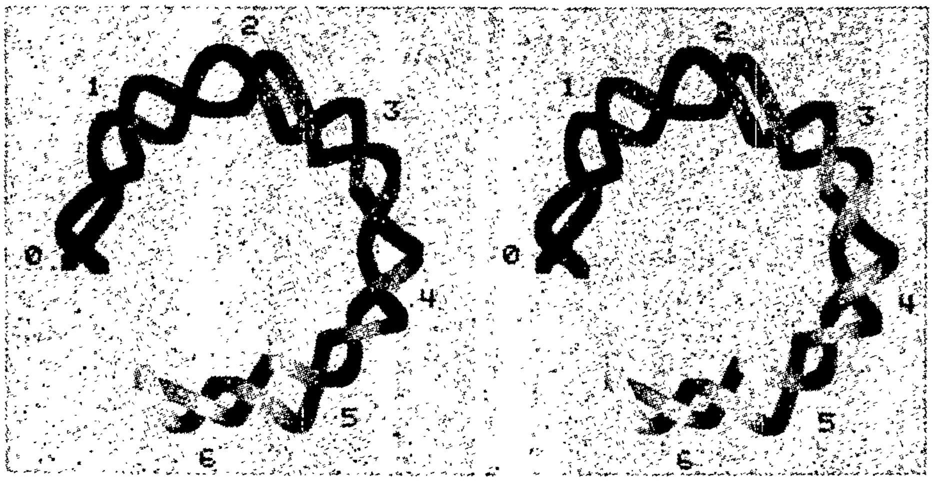

Fig. 2 The folded DNA double helix represented by the course of the phosphodiester backbones. Only one turn of the DNA superhelix as viewed down the superhelix axis is shown for clarity (as a stereopair). The points of intersection of the phosphodiester chains with each map section were joined by cubic spline fitting[56] to produce the two smooth curves shown. The superhelix is oriented such that the molecular dyad axis is horizontal and passes through the minor groove facing outward at position 0. The other positions where the minor groove faces outward are numbered accordingly. The same orientation of the dyad axis is used in Figs 2–6.

compared with a calculated value of 0.40. This agreement is as good as can be expected, as the contour level (55% of the difference between maximum and minimum peak heights) which should be chosen for the boundaries will depend on unknown factors such as small variations in particle position and orientation and local disorder in the histone N-terminal segments[21]. The counterions associated with the DNA and protein would also affect the partial specific volumes.

The core particles are pseudo-hexagonally packed in layers as described previously[6,17]. Most of the contacts between particles are made by DNA–DNA interactions, with one important exception. The H2A · H2B dimers on each flat face of the particle associate with the DNA of an adjacent particle in a head-to-tail fashion along the *b*-direction in the layers. Presumably nuclease trimming of the nucleosome has freed a DNA binding site on each dimer, making it available for interparticle associations. There is also a protein–protein interaction ($H3^2$–$H2B^1$) between layers of the crystals.

The DNA double helix and superhelix

The DNA double helix is in a right-handed B-form (see also ref. 6) and folded into a left-handed superhelix (Fig. 2). About 12 turns of the DNA double helix are clearly visible; the last half turn on each end is indistinct owing to the variable length of the DNA and crystal packing effects. As before[9], we mark the distance along the DNA by numbers from −7 to +7 (from end to end), taking as origin the point where the dyad axis passes through the double helix at the middle of the nucleosomal DNA. The minor groove faces directly outward from the particle at this point, position 0 (Fig. 3*a*), which corresponds to site 7 of the DNase I cutting pattern[22,23]. The positions of the integral numbers correspond approximately to the sites of attack (the local maxima in the frequency of cutting) by the enzyme DNase I[24]. These sites consist of pairs of cuts staggered by 1–3 bp on the two DNA strands[25].

The DNA has on average about 7.6 turns of double helix in a complete superhelical turn. As a result of this periodicity, the adjacent turns of the superhelix are arranged with a minor groove approximately opposite a major groove. The pitch of the superhelix is ~30 Å for the central turn measured between positions −3.8 and +3.8, but reaches a minimum value of 25 Å between positions −2.5 and +5.0. The pitch of the double helix measured along an arc of the superhelix is about 35 Å. At the resolution described here, the actual number of nucleotides per double helical turn cannot be determined. The precise nature of the distortions in the DNA should be apparent when the data to 5 Å resolution are included, as the phosphates should then be visible.

The DNA double helix does not take up a perfectly regular superhelical path as it winds around the histone octamer, but is bent fairly sharply or possibly kinked at several locations (Fig. 2). The DNA bend in the region of position +1 is itself not in direct contact with the histones, but bridges between an extensive histone interaction at position +0.5 on one side and lesser contacts on the other. A similar bend occurs at position +4, apparently due to the DNA–histone contact at position +3.5. The symmetrically related positions at −1 and −4 show similar DNA bending. These regions of high curvature are apparently unlike previously proposed kinks (for example, ref. 26), as the departure from good stacking is apparently spread over several base pairs. Despite the evident ovaloid shape of the superhelix as viewed down its axis (Fig. 2), its diameter (measured between axes of the double helix across the particle) is fairly constant at 86 ± 4 Å.

Because the widths of the major and minor groove seemed to depend on the degree of bending (Fig. 2), we measured them at both the inside and outside surfaces of the double helix at several sites which are exceptionally clear in the map. At period +1 for example, the minor groove width increases from 7 Å on the inside of the particle to 13 Å on the outside. Similarly, the major groove widths are 11 Å and 20 Å. The major groove appears to be more compressed than the minor groove on the inside of the most highly curved regions.

The positions of tightest DNA bending (±1, ±4) correlate well with the sites of greatest 'protection' from DNase I digestion[24] and enhanced reactivity with dimethyl sulphate[27]. Because no obvious protein density is seen extending around the outside of the DNA, it appears that the reduced nuclease cleavage rates do not arise through simple steric hindrance, but rather from distortions in the DNA conformation, or from a reduction of its flexibility due to tight binding by the histones. It has been shown for a double helical oligonucleotide of defined sequence that the cleavage rate for DNase I depends on the local variation in the screw of the double helix[28,29]. Conformational differences along the nucleosome superhelix might indeed lead to relative enhancements of nuclease cleavage rate and also of chemical reactivity. Dimethyl sulphate labelling of purines shows altered reactivity at only two bases as compared with free DNA[27], and these are located in the inward-facing major groove free of protein at positions ±1, where the double helix is sharply bent, and in the minor groove in contact with histone at ±0.5.

The histone octamer and DNA interactions

As mentioned above, features in the protein part of the map are clustered and correspond to the eight individual histone molecules. The assignment of histone H3 is confirmed by the location of the major binding site for the TAMM heavy atom cluster. This label falls precisely on the particle dyad axis (Fig. 3*a*), suggesting that this tetravalent compound bridges between two invariant sulphydryl groups, one from each H3. These are known to be close enough to form a disulphide bond[30]. Even though there are two −SH groups in each bovine H3, we can

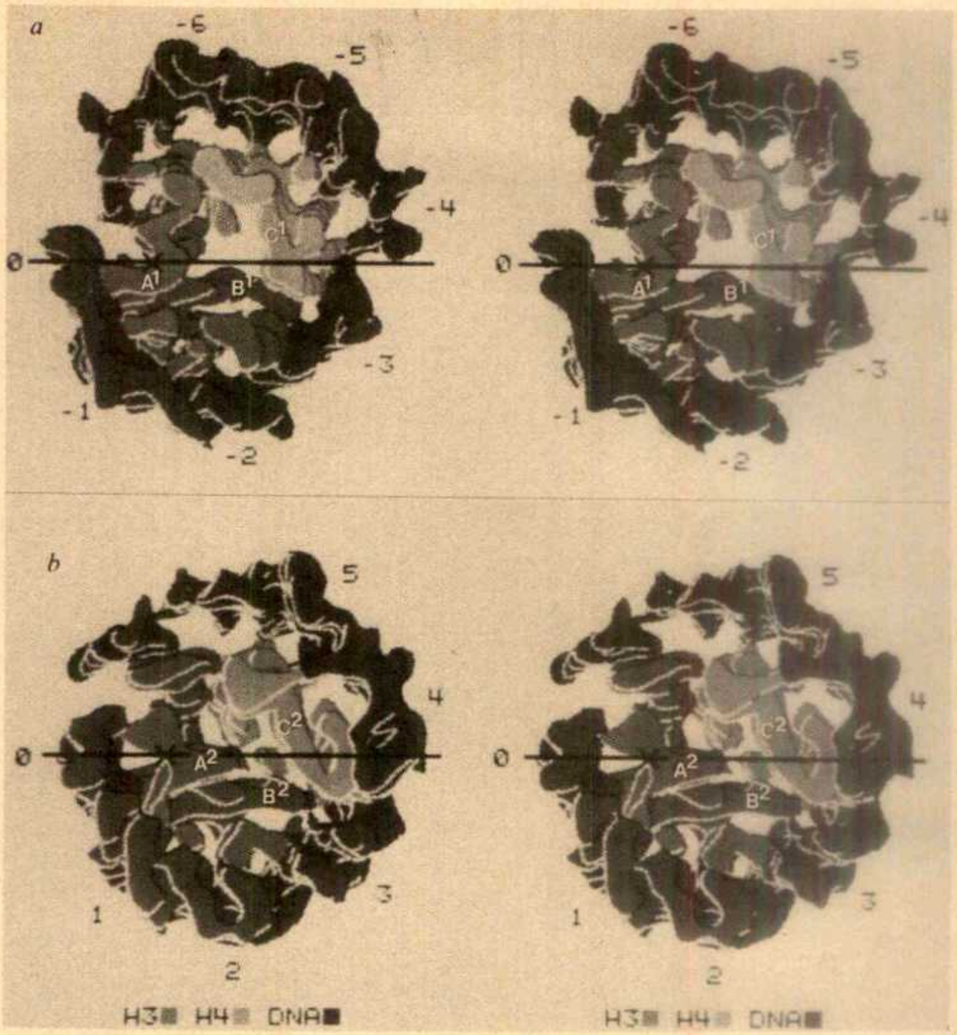

Fig. 3 The two halves of the H3·H4 tetramer and the central turn of the DNA superhelix, both viewed from inside outwards. The map is presented in the form of a stereo-pair of a computer-generated model and has here been sliced into two 15 Å thick slabs parallel to the flat faces of the core particle: *a*, sections −12 to −3; *b*, sections −1 to 6. The alternating groove structure of the DNA is seen particularly clearly from positions 0 to +4 in *b*. The half-tetramer in *b* has been rotated 180° about the dyad axis to give the same view as in *a*: thus the arc 1 to 4 fits against the arc −7 to −3 in the other half. The position of the molecular dyad axis was determined from the rods of histone density labelled B^1 and C^1, and B^2 and C^2. Some of the contours in the histone core have been removed to allow these rods to be seen. The TAMM heavy atom cluster site on the H3 dimer is indicated by a bold X.

be certain that cysteine 110 is the labelled group, because the level of mercurial binding and the intensity distribution in the X-ray patterns from TAMM-reacted crystals of bovine core particles are the same as those from chicken erythrocytes (data not shown), which contain only the two cysteine 110 residues. As can be seen in Figs 3 and 4, the heavy atom site lies between two rods of electron density ~20 Å long (A^1 and A^2) which abut the minor grooves of the DNA at sites −0.5 and +0.5. The H3 densities fold back from the DNA at these positions and extend across the particle for ~35 Å in long rods of density (B^1 and B^2).

Two other rod-like features ~35 Å in length (C^1 and C^2) are visible in the same map sections, but appear to be disconnected from the features defining the H3 region. Therefore, they are likely to be part of the H4 molecules. Shorter pieces of density fold back from the ends of these rods, and make substantial contact with the DNA minor grooves at positions −3.5 and +3.5. These grooves lie on either side of the particle dyad axis at the point where it passes between the two turns of the superhelix. Histones H4 also appear to make minor contacts with the outer superhelical turns of DNA from positions ±4 to ±5.

The two pairs of rod-like density, B^1C^1 and B^2C^2, prominent in the tetramer region, were aligned to determine the orientation of the non-crystallographic dyad symmetry axis (Fig. 3). Other features in the H3·H4 histone tetramer and the central turn of the DNA superhelix are well related by this dyad axis.

DNA–protein contacts are made on nearly every turn of the DNA double helix and are confined to the inner surface of the superhelix. If each such histone contact contained a positive charge, the degree of phosphate charge neutralization thereby afforded would be consistent with the value of 20% derived from the analysis of melting of core particle DNA[31]. If any parts of the histones larger than, say, an extended chain are bound to the outer surface of the DNA, they are disordered in the crystals because there are no places in the 7 Å map where the DNA grooves on the outside of the particle are obscured by protein density. The spaces between the turns of the superhelix are also free from obvious protein density.

In contrast to the tetramer, the pair of H2A·H2B dimers clearly depart from dyad symmetry in the crystals. The whole core particle forms the asymmetric unit, so that the two copies of each histone are not constrained to identical environments. Being on the outer surface of the particle, the H2A·H2B dimers are more susceptible to disturbance by crystal packing forces than is the internally located H3·H4 tetramer.

The $H2A^1 \cdot H2B^1$ dimer is a striking feature of the electron density map. The $H2B^1$ domain contains an ~40 Å long rod of density, D^1 (Fig. 5). Contacts with minor grooves are made at positions −3.5, −4.5 and −6.5 whereas the protein density runs roughly parallel with the major groove at −5. The $H2A^1$ domain extends over the DNA at position 0 to the outer edge of the core particle, and is bound to the major groove at site −3.5 of the DNA on the neighbouring particle (Fig. 5).

The second copy of the dimer is less well ordered and has apparently turned (anticlockwise from the position in Fig. 6) about a point in $H2B^2$ such that the body of $H2A^2$ is shifted by ~10 Å from the position which is symmetrically equivalent to $H2A^1$. This departure from symmetry may represent an intermediate position of this dimer during a quaternary structural change relative to the H3·H4 tetramer. Like $H2A^1$, $H2A^2$ is associated with the DNA at position −7 on an adjacent particle in the crystal. In order to make this DNA interaction, the

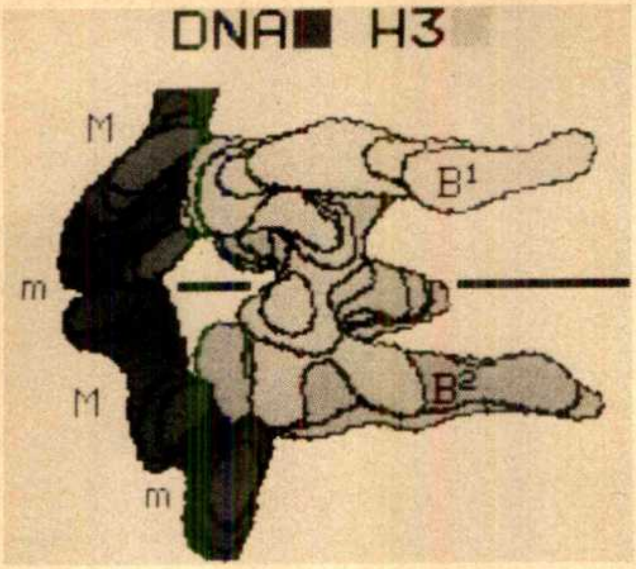

Fig. 4 The H3 dimer and its contact with the middle region of the superhelix. The terminal regions of the long rods, presumably α-helices, make extensive contacts with the minor grooves of the DNA one-half turn of the double helix away on either side of the dyad axis, represented by the solid line. The minor groove faces away from H3 on the dyad.

$H2A^2 \cdot H2B^2$ contacts with the tetramer must be rearranged as compared with $H2A^1 \cdot H2B^1$.

Linker DNA and H1 binding

Nucleosomes which are nearest neighbours along the course of the DNA in chromatin are connected by the linker DNA; its path in chromatin is unknown and may vary. In the core particle structure determined here, the spaces to either side of the DNA at position 0 are blocked by H2A molecules (Fig. 6). If this is also true in solution, the linkers, which would in a nucleosome extend beyond positions −7 and +7, could not simply follow the smooth superhelical course set by the central turn of DNA, as has been suggested[5,32]. The H2A molecules extend to the outer edge of the particle, and are likely to cause the linkers to make angles of roughly 50° to 60° with the molecular dyad axis. Chromatin containing very short linker lengths (that is, 0–10 bp) would then require the DNA to bend sharply or kink, perhaps as seen on the core particle itself. It could be argued that in solution the H2A · H2B dimers take up a more central position in the particle and do not protrude over position 0, but this would entail a major distortion on the diametrically opposite side of the superhelix at position ±4, which we consider unlikely.

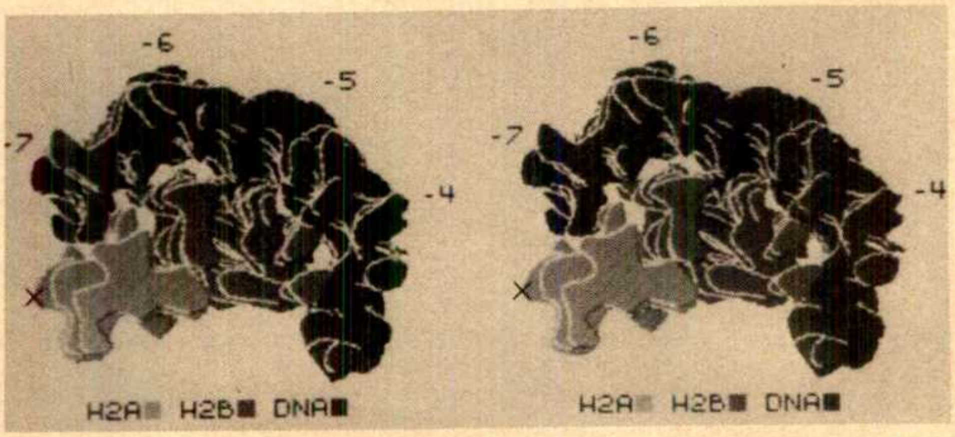
This proposed arrangement of the DNA one double helical turn beyond the observed ends of the core particle DNA suggests how H1 may be bound on the nucleosome. Electron microscopy studies of H1-containing and H1-depleted chromatin[33] and the isolation of the chromatosome (which contains H1 and an additional 20 bp of DNA[34]) indicate that H1 is associated with both ends of the superhelix as they make the transition into the linker region. The three DNA segments −7 to −8, +7 to +8, and −1 to +1 would form, when viewed edge-on down the dyad axis, a three-sided cavity, which would provide a reasonable binding site for the H1 globular domain[35]. The core histones that would be closest to H1 are the H2A molecules, as was indicated from chemical cross-linking studies[36,37].

Biological implications

The arrangement of the histones and their degrees of contact with the DNA are suggestive of the roles of the different histones in the assembly of the nucleosome[9,17]. The most substantial contacts are made between the H3 · H4 tetramer and the central turn of the DNA superhelix, and, as was foreseen[9], account for the fact that the tetramer alone can protect about 80 bp of DNA against cleavage by micrococcal nuclease[38,39]. Weaker interactions also occur between the tetramer and the outer turns of the superhelix and explain how the tetramer alone can also organize ~140 bp into a loose nucleosome-like particle[40,41]. The H2A · H2B dimers add to each exposed face of the tetramer, binding to the DNA of the last half turns of the superhelix and increasing the overall stability of the nucleosome.

The H3 dimer within the tetramer binds to DNA in a way which superficially resembles the DNA binding model suggested for the sequence-specific proteins from prokaryotes (for example, cro repressor[42], catabolic activator protein[43] and the N-terminal fragment of λ *c*I repressor[44]). These proteins form dimers whose dyad symmetry axis could align with a local dyad axis in the DNA structure as we have found for the H3 dimer, but the details may differ. For the prokaryotic proteins, a pair of α-helices may contact the edges of the bases in the major grooves of the DNA one half turn to either side of the dyad, whereas, in the case of the H3 dimer, the ends of presumptive α-helices lie against the minor grooves of the DNA one-half turn of the double helix away from the central dyad axis (Fig. 4). Another variation is seen in the complex of the *Eco*RI restriction enzyme and its specific DNA recognition sequence. The protein and DNA are oriented as for the H3 dimer–DNA interaction, but dimerically related α-helices contact the bases in an expanded major groove facing inward on the dyad[45].

Fig. 5 The $H2A^1 \cdot H2B^1$ dimer and outer half turn of the DNA superhelix, viewed from the inside. The stretch of DNA from its end position at −7 to position −3.5 is shown: the groove structure in the region −4 to −5 is very clear. The $H2B^1$ domain includes a number of distinct features such as the partly buried rod of density (D^1) crossing the length of the domain, and a piece of density running roughly in the major groove at position −5. The point on the $H2A^2$ domain which contacts the DNA of the adjacent particle (in the horizontal direction) at position −3.5 is indicated by the X. This contact is repeated along the crystallographic two-fold screw axis in the *b*-direction.



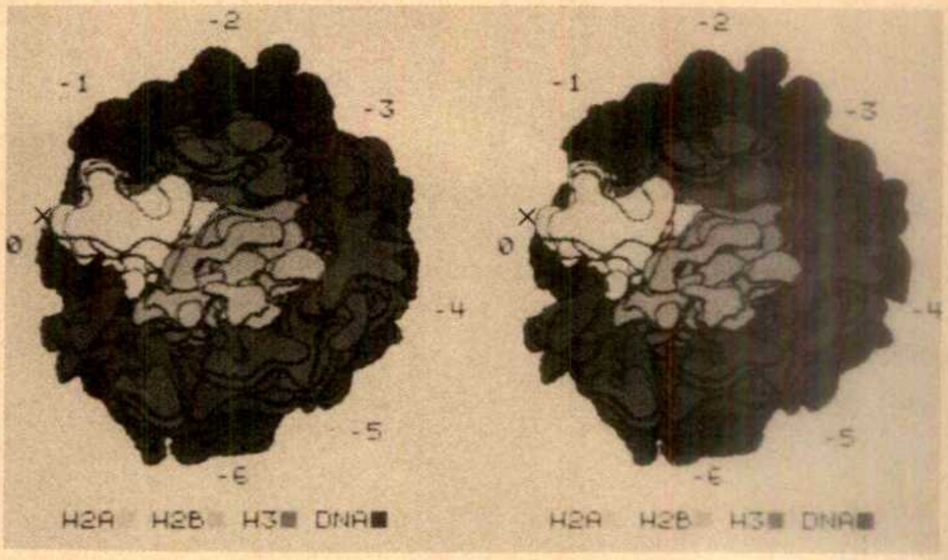


Fig. 6 The location of the $H2A^1 \cdot H2B^1$ dimer in the nucleosome core particle. The entire core particle is shown (sections −21 to +13) to illustrate that $H2A^1$ is positioned over the central turn of the DNA superhelix near position 0. The point marked X is the same as in Fig. 5.

The sharp bends in the DNA path on the nucleosome suggest a structural explanation for the observation that certain DNA sequences are specifically positioned on the histone octamer[46,47], a phenomenon that has been called nucleosome phasing[48] (but see ref. 49). It may be that on account of their relative flexibility, certain short nucleotide sequences are preferentially accommodated at the sharp bends, whereas others may be preferentially excluded[50,51] because of their stiffness. The interplay of these preferences in different regions of a DNA sequence of roughly nucleosome length could result in fixing it at a favoured position. This mode of positioning would not depend directly on specific interactions between the histones and certain base pairs, although it does not, of course, exclude them.

The compact structure that the genomic DNA attains in the nucleosome is essential for chromosome segregation during mitosis, yet the nucleosome cannot be a static structure throughout the cellular processes of transcription and replication. Several recent studies indicate that the histone octamer of transcriptionally active chromatin dissociates from the DNA[52] or takes on an altered structure[53,54]. In the crystal structure, one of the H2A·H2B dimers appears to have moved due to an interaction of H2A with the DNA of another particle. This suggests how the nucleosome might disassemble in response to an alteration in the path of the linker DNA joining nucleosomes in chromatin, perhaps in response to the passage of DNA or RNA polymerase. It seems possible that the dimer would dissociate from the tetramer, while both oligomers maintain separate contact with the DNA. The movement of the H2A·H2B dimer with respect to the histone tetramer is of particular interest in view of the report of a complex formed between RNA polymerase II and nucleosome core particles enriched in transcribed DNA sequences, because this complex lacks one of the dimers[55].

We thank S. J. Lippard and T. O'Halloran for their gifts of the TAMM and PIP heavy atom cluster compounds, the preparation and use of which will be described elsewhere in a joint communication (S.J.L., T.O'H., T.J.R. and A.K., in preparation).

We dedicate this paper to Dr Max Perutz on the occasion of his 70th birthday.

Different modes of Ca channel gating behaviour favoured by dihydropyridine Ca agonists and antagonists

Peter Hess, Jeffry B. Lansman & Richard W. Tsien

Department of Physiology, Yale University School of Medicine, New Haven, Connecticut 06510, USA

Single cardiac transmembranous Ca channels have three modes of gating behaviour in the absence of drugs, expressed as current records with brief openings (mode 1), with no openings because of channel unavailability (mode 0 or null mode) and with long-lasting openings and very brief closings that appear only rarely (mode 2). The dihydropyridine Ca agonist Bay K 8644 enhances Ca channel current by promoting mode 2, while the Ca antagonists nitrendipine and nimodipine inhibit the current by favouring mode 0.

DIHYDROPYRIDINES such as nifedipine and nitrendipine are among the newest and most interesting of the many agents that modify Ca channel activity in excitable cells[1,2]. As therapeutic agents, they have already gained wide use in the treatment of cardiovascular disorders[3-6]; as specific ligands, they open the way towards eventual biochemical purification and reconstitution of Ca channels[7-10]. Questions about the mechanism of their action have been raised by the discovery of 'Ca agonists', such as Bay K 8644 and CGP 28 392 (refs 11, 12), which increase cardiac contractility and divalent cation influx[11-16] even though they are dihydropyridines and thus very similar in structure to nifedipine and other 'Ca antagonists'. How can such closely related compounds produce effects that seem so diametrically opposite? Here we report analysis of Ca agonist and Ca antagonist effects on Ca channel activity of single heart cells and single Ca channels. We find that Bay K 8644 increases the chances that the channel will show a mode of gating marked by long opening and brief closing events. The same type of gating can be seen occasionally in the absence of drug. On the other hand, nitrendipine and nimodipine exert their Ca antagonist effect by increasing the proportion of sweeps where the channel fails to open. The results provide an explanation for partial agonist or antagonist actions; in particular, we find that the effects of nitrendipine include a Ca agonist component.

Methods

Single ventricular cells were obtained from guinea pig or frog hearts by enzymatic dispersion[17,18], and whole cell membrane current recordings were made under voltage clamp conditions using suction pipette methods of Lee *et al.*[19] (guinea pig) or Hamill *et al.*[20] (frog). Patch clamp recordings of single Ca channel activity were made from cell-attached patches on guinea pig ventricular cells[21,22] with patch pipettes containing 110 mM $BaCl_2$, 10 mM glucose and 10 mM HEPES (titrated with $Ba(OH)_2$ to *p*H 7.5). The cells were bathed in a solution containing 10 mM KCl, 140 NaCl, 1 mM $MgCl_2$, 10 mM glucose and 10 mM HEPES (titrated with NaOH to *p*H 7.5). In some of the experiments, the external solution also contained 0.5 mM EGTA. Current signals were filtered with an eight-pole Bessel filter with a cut-off frequency (3 dB) of 1 kHz, and sampled at 5 kHz. Automated analysis of the digitized signals was carried out with procedures similar to those previously described[21,22]. The analysis program disregarded open or closed periods that lasted up until the time of repolarization. The figures show results from patches containing only one channel, as judged by the absence of a multiple conductance level. All experiments were carried out at room temperature (22 °C).

Ca channel current in single cells

The Ca agonist compound Bay K 8644 strongly enhanced Ca channel current in both guinea pig and frog ventricular cells. With 10 mM external Ca, and test depolarizations from −60 mV to +10 or +20 mV, 1 μM Bay K 8644 increased the peak inward current by 3.0 ± 0.3 fold (s.e.m.) in guinea pig myocytes ($n = 6$) and 4.05 ± 0.52 fold in frog ventricular cells ($n = 7$). Bay K 8644 at 10 μM gave no greater enhancement than at 1 μM; half-maximal effects were obtained at concentrations of 30–100 nM. At maximally effective doses, Bay K 8644 increased whole cell Ca channel current within seconds, and in all cases the enhancement was sustained.

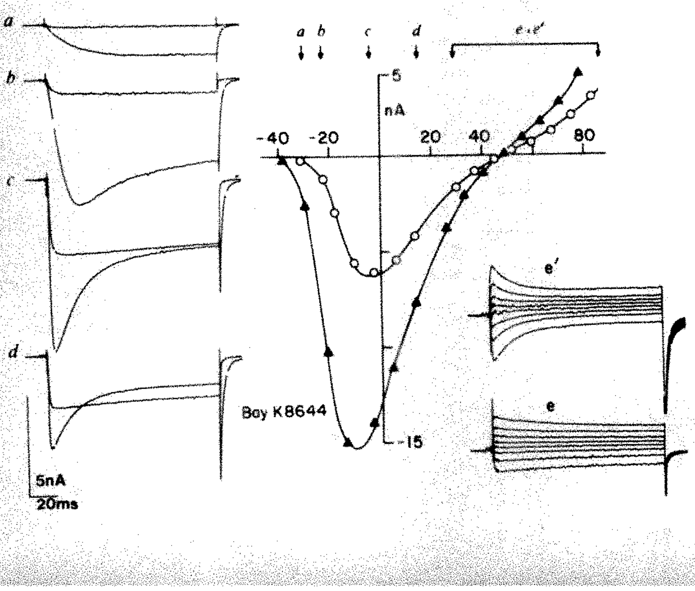

Fig. 1 Voltage-dependent effect of Bay K 8644 on Ca channel currents carried by Ba^{2+}. Single guinea pig ventricular cells were studied with a suction pipette for voltage clamp and internal dialysis[19]. Each panel shows current signals evoked by step depolarizations from a holding potential of −60 mV, in the absence of drug (smaller peak current, more rapidly decaying tail current), and in the presence of 1 μM Bay K 8644 (larger peak current, more slowly decaying tail current). *a–d*, Depolarizations to within 1 mV of −31, −23, −3, and +15 mV. *e*, *e'*, Families of records taken over the voltage range between +27 and +80 mV to show reversal of Ca channel current with Bay K8644 (*e'*) and in control (*e*). The current-voltage diagram plots peak current against test potential. Series resistance compensation for 0.75 MΩ out of a total pipette resistance of 0.9 MΩ. Linear leak currents and capacity currents have been subtracted from the current signals. External solution contained (mM) 10 $BaCl_2$, 85 Cs-aspartate, 2.85 $MgCl_2$, 5 glucose, and 10 HEPES titrated with CsOH to *p*H 7.4. Internal dialysate contained (mM) 75.5 Cs-aspartate, 75.5 Cs-phosphate, 5 glucose, and 10 HEPES titrated with CsOH to *p*H 7.0. Cell 205G.

The Ca agonist altered the voltage- and time-dependence of Ca channel currents carried by either Ca^{2+} or Ba^{2+}. The analysis of Ba current (charge carried by Ba^{2+}) is somewhat simpler because of the absence of Ca-induced Ca channel inactivation[23]; Figure 1 illustrates the effect of Bay K 8644 (5 μM) on Ba current in a whole-cell suction pipette recording from a guinea pig myocyte. The agonist-induced enhancement of peak current was largest at weak depolarizations (where the current was small in the absence of drug) and became progressively smaller with increasing depolarization. For example, the enhancement was ~10-fold at −31 mV (*a*) and only ~1.8-fold near +80 mV (*e*, *e*′). As the current–voltage relationship indicates, the current through the Ca channel reversed near +50 mV (due to a balance of Ba influx and Cs efflux[24]) and the reversal potential remained unchanged with agonist.

The time-dependence of Ba current through Ca channels was also changed by the Ca agonist. In the presence of Bay K 8644, the current showed a greater tendency to decay. As the depolarizing pulse grew stronger, the enhancement of decay was so great that the agonist current signal was smaller than the control record by the end of the pulse, regardless of the polarity of the current (*d*, *e*, *e*′). Inward tail currents also decayed more slowly following a repolarizing step.

The pronounced changes in kinetics suggest that Ca channel gating is modified by Bay K 8644. To investigate this possibility, we carried out patch clamp recordings of single Ca channel activity.

Long-lasting channel openings

Activity of single Ca channels was recorded from cell-attached patches on guinea pig ventricular cells with 110 mM Ba in the pipette as the charge carrier (Fig. 2*a*, *b*). Ca channel activity was seen in the form of brief pulses of inward current in the absence of drug as in previous studies[21,25]. The test depolarization was kept small enough to give large, easily resolved unitary currents. Exposure of the cell to Bay K 8644 did not detectably alter the amplitude of the unitary event, but it produced a striking change in the pattern of channel opening. In many of the sweeps, the channel spent the majority of its time open, rather than closed; channel openings were very much prolonged; channel closings were abbreviated. As a result of these effects, the average current signal in the presence of agonist (Fig. 2*d*) was about 11-fold greater than its amplitude before drug (Fig. 2*c*). This response was typical of results from five patches, and reflected the whole-cell response at comparably weak depolarizations (Fig. 1*a*) in the degree of enhancement and in the absence of a drug-promoted relaxation of inward current.

When the agonist effect was large, and the drug dose was at a maximally effective concentration as in Fig. 2*b*, a substantial fraction of sweeps still contained no detectable openings or only rapidly flickering openings like those found in the absence of drug. Such sweeps are easily differentiated from sweeps with long openings and short closings. The combination of both types of behaviour provides an interesting clue to the agonist's mechanism of action.

Sweep-to-sweep variations in behaviour are illustrated for the same experiment by plotting the probability of a channel being open (*p*) for each sweep (Fig. 3*a*,*b*). The value of *p* was obtained by integrating over a period when the current signal was steady (see Fig. 3 legend). In the control run (Fig. 3*a*), *p* was less than 0.20 in all but one of the sweeps. After exposure to Bay K 8644, changes in *p* were immediate and well-maintained throughout the 15 min exposure to the drug (Fig. 3*b*). In the presence of the agonist, the distribution of *p* values is strikingly bimodal: over the range between $p = 0.5$ and $p = 1.0$ a new group of *p* values appears; however, between $p = 0$ and $p = 0.5$, the distribution remains similar to that in the absence of drug (Fig. 3*c*, *d*).

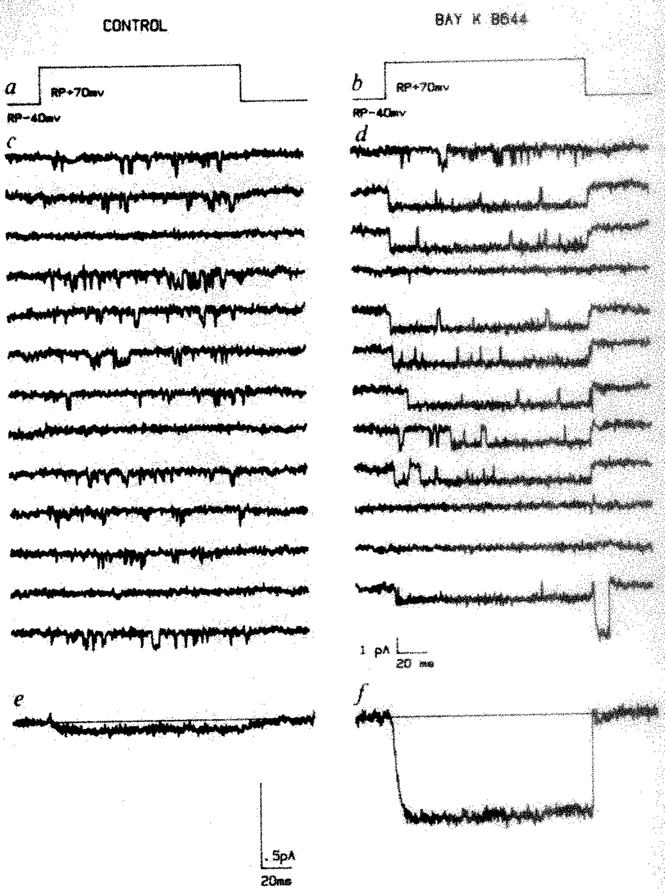

Fig. 2 Patch clamp recording of single Ca channel activity in the absence (left column) and presence of 5 μM Bay K 8644 (right column). Cell-attached patch. *a*, *b*, Voltage protocol RP, resting potential ~ −60 mV as determined by measurement of open channel current-voltage relations (data not shown). Pulses were applied once every 3 s. *c*, *d*, Representative current signals (consecutive sweeps). Linear leak and capacity currents have been subtracted. *e*, *f*, Averaged current signals from all the sweeps in each run (vertical scale is different in *c*, *d*). Cell 6A.

Sweeps with low *p* and high *p*

Taking advantage of the bimodal distribution of *p* values, we separated records taken in the presence of Bay K 8644 into two groups of records for analysis of the kinetics of opening and closing: 'low *p*' sweeps with $p < 0.3$, and 'high *p*' sweeps with $p > 0.65$ (Fig. 4). The behaviour of low *p* sweeps in the presence of agonist is very similar to that in the absence of drug (Fig. 4, left and middle columns). Both of these open time histograms are fitted by a single, rapidly decaying exponential ($T \sim$ 0.5–0.6 ms). Both of the shut time distributions are well-fitted by the sum of two exponentials as described elsewhere[21,22]. The mean latency-to-first opening is similar in both cases (21 ms control, 19 ms for low *p* sweeps in Bay K 8644). The percentage of sweeps with no openings is also very similar (132/420 = 31% in control and 42/127 = 33% for the low *p* sweeps after agonist).

The behaviour of the high *p* sweeps is strikingly different. The open time histogram shows a predominance of long openings (mean value ~20 ms), as expected from the records illustrated in Fig. 3. The distribution fits a single exponential reasonably well, except for a surplus of brief openings in the first few bins, which may reflect imperfect exclusion of the low *p* behaviour with its much greater density of open events per unit time. The shut time distribution is fitted by the sum of two exponentials, as in the other two cases, but the mean closed time is much briefer. Similarly, the cumulative histogram of latency-to-first opening is biased towards shorter times. The combination of longer openings and shorter closings accounts for the extremely high values of *p*.

The results from this patch were representative of a total of three experiments with 5–10 μM Bay K 8644. In an experiment with 100 nM drug, the high *p* sweeps showed similar open and closed time distributions; the proportion of high p sweeps was simply lower than with maximally effective doses of drug.

Multiple modes of channel gating

The analysis is consistent with the idea that the Ca channel switches between different modes of channel gating. Figure 5*a* presents our working hypothesis. We use the terms mode 0, mode 1, and mode 2 to refer to the three distinct forms of gating behaviour. Mode 1 is characterized by brief (~1 ms) openings occurring in rapid bursts. The most obvious form of gating in the absence of drug, it has been the main focus of single channel recordings up to now[21,22]. The probability of openness in this mode is relatively low at membrane potentials where the unitary current is easily resolved, although it must be remembered that p can approach levels as high as 0.7 at stronger depolarizations[21,25]. The observed distributions of open and shut times have been interpreted in terms of two closed states (C1, C2) and one open state (O) (see refs 21, 22, 26). Mode 2 can be distinguished by relatively long-lasting channel openings (~20 ms) and typically brief closings. Probability of channel openness is typically high (>0.7) even at relatively negative test potentials. The distributions of open and closed times in Fig. 4, right column are compatible with a C1-C2-O scheme, with very different values of rate constants than those appropriate for mode 1.

Although mode 2 behaviour is most easily studied after administration of Ca agonist, it can also be seen in the absence of drug. For example, Fig. 3*a* shows a sweep with a p value of ~0.85; this sweep has openings lasting 3.6, 9.5, 10.8, 3.2, 0.6, and 77.5 ms, typical of what we define as mode 2. The sweep was the only one out of 420 that clearly showed long openings. In a total of 11 patches with one or two channels, sweeps with long openings and unusually high p typically appeared at a rate of about 1%, with a wide range (0.4–11%). Figure 5*b–e* illustrates the behaviour of the patch with the highest incidence of sweeps showing intrinsic mode 2 behaviour. Two main points can be made. First, sweeps with high p appear significantly clustered in time (Fig. 5*b*). Second, sweeps with high p in the absence of agonist show a pattern of channel opening and closing (Fig. 5*d*) very similar to that found in the presence of agonist (Fig. 2*b*). For example, in the experiment illustrated in Fig. 5 the mean open time in the high p sweeps was 16.4 ms, close to the ~20 ms time constant of the slow exponential in Fig. 4*f*. Similarly good agreement was found in other experiments: average values for the mean open time of high p sweeps were 19.0 in control (93 sweeps, 7 cells) and 18.2 in the presence of Bay K 8644 (338 sweeps, 4 cells).

Mode 0 or null mode refers to a condition or conditions where the channel is unavailable for opening. It is expressed by sweeps showing no openings, in excess of those empty sweeps expected from the C1-C2-O kinetics of mode 1. Voltage-dependent inactivation is one factor that increases the proportion of time a channel spends in mode 0. However, we found an excess of null sweeps even with holding potentials negative enough to achieve maximal removal of voltage-dependent inactivation.

The distinction between mode 0 and 1 can be demonstrated in at least two ways. The cumulative histogram of first latency (Fig. 4*d*) levels off at about 70%. This runs contrary to a simple C1-C2-O model, which predicts that the saturating level should be 100% (eventually, the channel should reach the open state long enough for an event to be detected). As the curve falls 30% short of certainty it appears that the channel was simply unavailable for opening at the test potential 30% of the time.

Another way of distinguishing mode 0 from mode 1 relies on the histogram of p values, as in Fig. 3*c* for example. The first two bins of the histogram largely represent sweeps for which no openings could be detected. When these sweeps are disregarded, the remaining distribution rises smoothly to a peak at the fifth bin and then falls smoothly, as might be expected for a single type of gating behaviour, namely mode 1.

By either of these criteria, the vast majority of patches in our experiments show an appreciable number of null sweeps in excess of those expected from C1-C2-O kinetics. A similar excess has been observed, but not commented on by other investigators (for example, ref. 27). Like sweeps showing mode 2 behaviour, null sweeps show a tendency to follow each other (see Fig. 5 legend).

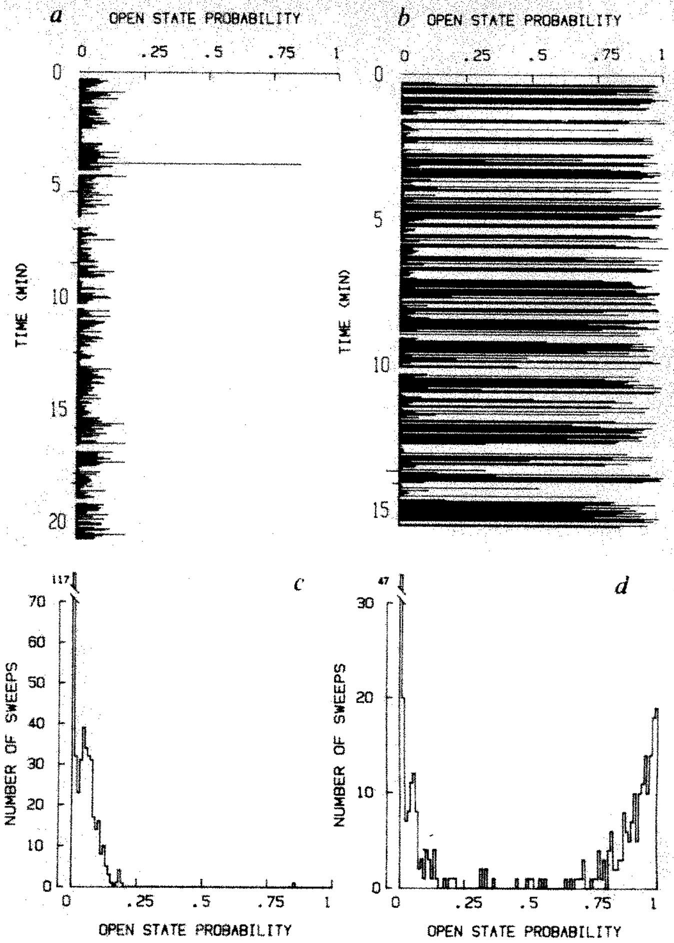

Fig. 3 Influence of Bay K 8644 on probability of channel openness (p) during individual sweeps. Control (left), 5 μM Bay K 8644 (right). In *a* and *b*, p is plotted against time. Gaps along the time axis indicate sweeps used to measure leak conductance or sweeps marred by noise interference. *c*, *d*, Histograms of p values for the runs shown in *a*, *b*. Each bin is 0.008 wide. For each sweep, steady-state values of p were determined as $p = \langle I \rangle / i$, where i is the unitary current, and $\langle I \rangle$ is the steady-state value of current, averaged over a period from 22 ms after the depolarizing step until the end of the pulse. Sweeps with no detectable openings ('nulls') have near-zero values of p, and show up in the first few bins. For example, in panel *c*, bins 1 to 5 contain 108, 18, 4, 1 and 1 nulls respectively; if the null sweeps had been excluded from the histogram in *c*, the distribution of p values would rise to a single peak and fall smoothly.

Mechanism of agonism and antagonism

The identification of different modes of Ca channel gating leads naturally to a hypothesis for the mechanism of action of dihydropyridine (DHP) Ca agonists and antagonists (Fig. 5*a*). We propose that the binding of these drugs does not plug the pore, but favours one or more modes of gating instead. Within a mode, the kinetics of gating transitions need not be different when DHP occupies its binding site (see Fig. 6). Pure agonist effects arise when mode 2 is specifically favoured, and pure antagonist effects result when mode 0 is preferentially stabilized; these extremes encompass a wide range of intermediate possibilities for 'partial agonist' or 'partial antagonist' effects[34].

We observed effects of 5–15 μM nimodipine consistent with the above hypothesis for a pure antagonist: at these drug concentrations we found that the reduction of the averaged current

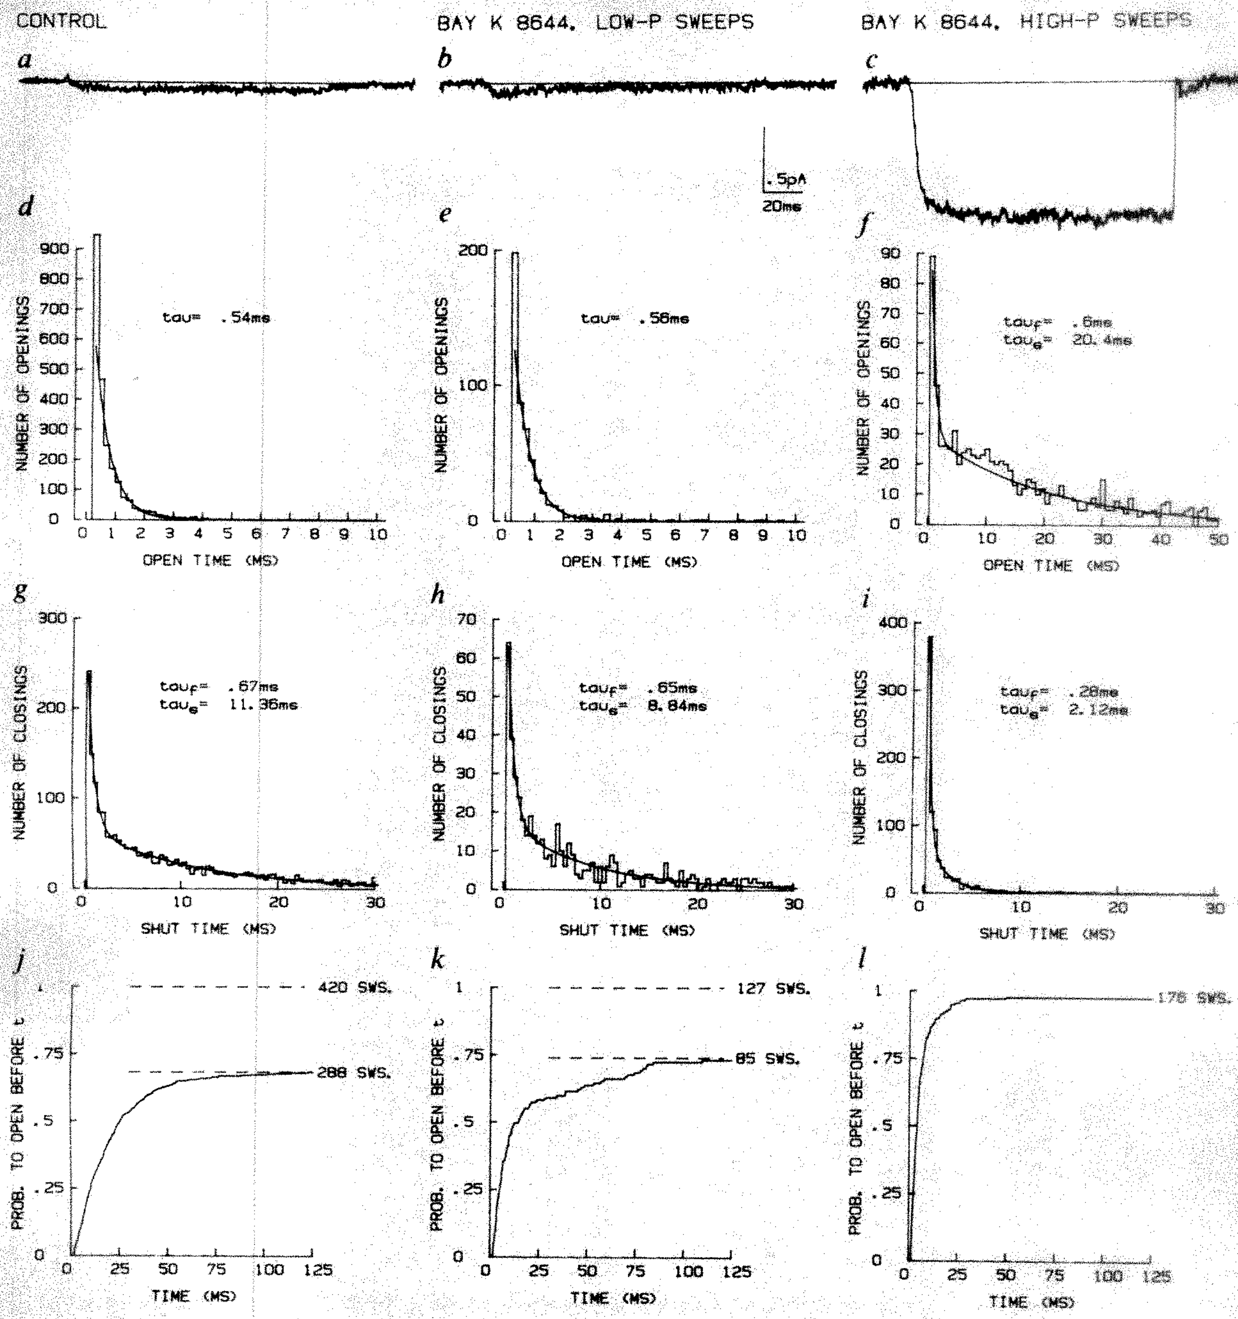

Fig. 4 Effect of Bay K 8644 on Ca channel kinetics. Left column, analysis of all sweeps from the control run; middle column, all sweeps from agonist run with $p < 0.3$; right column, all sweeps from agonist run with $p > 0.65$. The rows show averaged current records (first row), distributions of open times (second row), closed times between openings (third row), and cumulative distributions of the latency to first opening (fourth row). Smooth curves in panels *d* and *e* are single exponentials (the fits ignore the first bin of the histogram data). Smooth curves in panels *f–i* are sums of two exponentials. Fits were obtained by minimizing χ^2, using a computer program provided by Dr R. S. Kass.

was caused by an increase of the proportion of sweeps with no openings, whereas we found no clear evidence for a change in open or closed time distributions.

Mixed effect of nitrendipine

Although nitrendipine is generally assumed to be pure antagonist, we found that the net inhibitory effect of this dihydropyridine is the resultant of agonist as well as antagonist components. Figure 6 illustrates the response of a single Ca channel to 5 μM nitrendipine, a partially inhibitory dose in the presence of the 110 mM Ba (ref. 24). The control run included a large number of empty sweeps, as well as sweeps with bursts of flickery openings (mode 1), and sweeps with long openings, some lasting beyond the repolarizing step (mode 2, not shown). Nitrendipine altered channel activity in several ways. As with nimodipine, the proportion of sweeps with detectable openings was greatly decreased. This is evident from the plot of cumulative latencies to first opening (Fig. 6*g*), which levels off at a level roughly half that of control. When a more complete reduction of inward current was obtained at 10 μM nitrendipine in other experiments, the proportion of empty sweeps approached 100%. We attribute these effects to stabilization of mode 0, in line with a pure antagonist action.

Other aspects of the nitrendipine response were rather surprising. (1) The percentage of sweeps with $p > 0.5$ was not decreased; (2) a larger percentage of sweeps contained long openings, and the distribution of open times was prolonged (Fig. 6*e*), (3) closed times were abbreviated (Fig. 6*f*); (4) latencies-to-first opening were shortened (Fig. 6*a*). In all of these respects, nitrendipine resembles Bay K 8644.

The agonist-like effect of nitrendipine is most clear at the time of peak inward current. The peak amplitude of the averaged

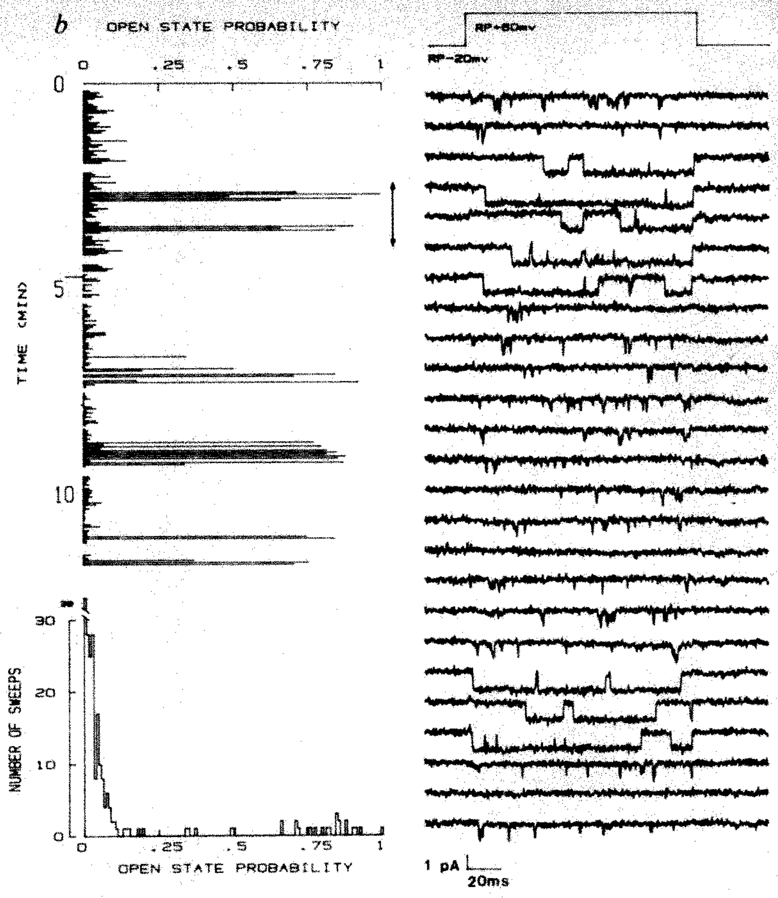

Fig. 5 *a*, Hypothetical modes of Ca channel gating. In the absence of drug, transitions between modes are assumed to be much slower than gating reactions within modes; details of inter-mode connections are left unspecified and require further study. At the test potentials studied, mode 1 and mode 2 are distinguished by qualitatively different patterns of opening and closing. This is put in terms of a kinetic model for Ca channel gating with two closed (C1, C2) and one open (O) state: rate constants for transitions between the states are assigned different values depending upon the mode. No gating reactions are depicted for mode 0 because it represents condition(s) in which the channel is unavailable for opening at the test depolarization. Since voltage-dependent inactivation is one factor that biases the channel towards mode 0, the rate constants for transitions to and from mode 0 are presumably voltage-dependent. The voltage-dependence of transitions between mode 1 and mode 2 is not known. *b–d*, Spontaneous appearance of sweeps with long-lasting openings and high *p* in the absence of drug. Experimental conditions as in Fig. 2*a*. RP ≃ −55 mv. *b*, probability of channel openness during 250 sweeps at 0.33 Hz. Gaps correspond to measurements of leak current with weak depolarizing pulses. *c*, Histogram of *p* values for the set of sweeps shown in *b*. In 31 sweeps, no openings were detected by the analysis program. *d*, Representative current records associated with the depolarizing pulse shown above. Twenty-five records were taken sequentially during the period marked in *b*, illustrating the tendency for mode 2 activity to occur in clusters of consecutive sweeps. The incidence of high *p* sweeps following immediately after a previous high *p* sweep was (11/21) = 52%, significantly higher than the overall incidence of high *p* sweeps (21/198) = 11% (χ^2, $P < 0.0001$). The incidence of null sweeps immediately after a preceding null sweep was (8/29) = 29%, significantly higher than the overall incidence of null sweeps, (30/198) = 15% (χ^2, $P < 0.05$). Cell 5F. In the presence of Bay K 8644, sweeps with high *p* values also tended to follow each other. For example, in the run shown in Fig. 3*b*, the incidence of high *p* sweeps was (176/316) = 56% while the incidence of high *p* sweeps following a previous high *p* sweep was (118/176) = 67%. This difference is also highly significant, $P < 0.0005$).

current remains almost unchanged (compare Fig. 6*c*, *d*), despite a doubling of the number of empty sweeps; this can only mean that *p* increased in the non-empty sweeps. The increase in *p* is associated with an increase in the number of long openings relative to the number of short openings (Fig. 6*e*). The overall inhibitory action of nitrendipine is more obvious toward the end of the depolarization since the average current decays more quickly in the presence of the drug (Fig. 6*f*). Individual records show a corresponding tendency for openings to occur towards the beginning of the pulse and not towards the end. When the faster decay of mean current was first observed with global current recordings[24,28], it was attributed to open channel block[24]. We now favour the interpretation that the faster decay results from antagonist-promoted inactivation (see below).

Activity of other dihydropyridines

Nitrendipine is not exceptional in its mixed effects. For example, nifedipine is used widely for its inhibitory action, but it can increase cardiac contractility at low doses[11,29]. The drug CGP 28 392 has agonist effects on contractile activity in heart and smooth muscle[12] and Ca fluxes in cultured cells[16] but its presence partially occludes the stimulatory effect of Bay K 8644 (ref. 16). Bay K 8644 itself is probably not a pure agonist. Sanguinetti and Kass[25] have reported that this drug increases Ca channel current in Purkinje fibres when the holding potential is negative, but reduces it when the holding potential is positive to −40 mV. We have seen similar effects of holding potential on the effects of Bay K 8644 in single ventricular cells. A partial antagonist effect may also be involved in the acceleratory effect of Bay K 8644 on Ba current decay with stronger depolarizations (Fig. 1).

Conclusions

Although this work began with an analysis of the effects of Ca agonists and antagonists, the experiments led us to some unexpected conclusions about the fundamental properties of Ca channels. We believe that the strikingly long openings seen with Bay K 8644 are not a new form of gating, but an intrinsic form of gating (mode 2) whose likelihood is merely enhanced by the drug. Without the agonist-promoted activity as a guide, the intrinsic mode 2 activity might be overlooked, since it appears only rarely in most experiments, and contributes only a small number of events per sweep to histograms of open or closed times. But once attention is focused on the mode 2 pattern of long openings and short closings, even single sweeps of this type of activity can be easily picked out. The distinction between mode 1 and mode 2 is particularly clearcut at weak depolarizations where the open probability in mode 1 is low.

Our results provide an attractive explanation for how structurally similar dihydropyridines can exert seemingly opposite effects on Ca influx. They argue against the idea that the inhibitory action of nitrendipine and other Ca antagonists reflects a

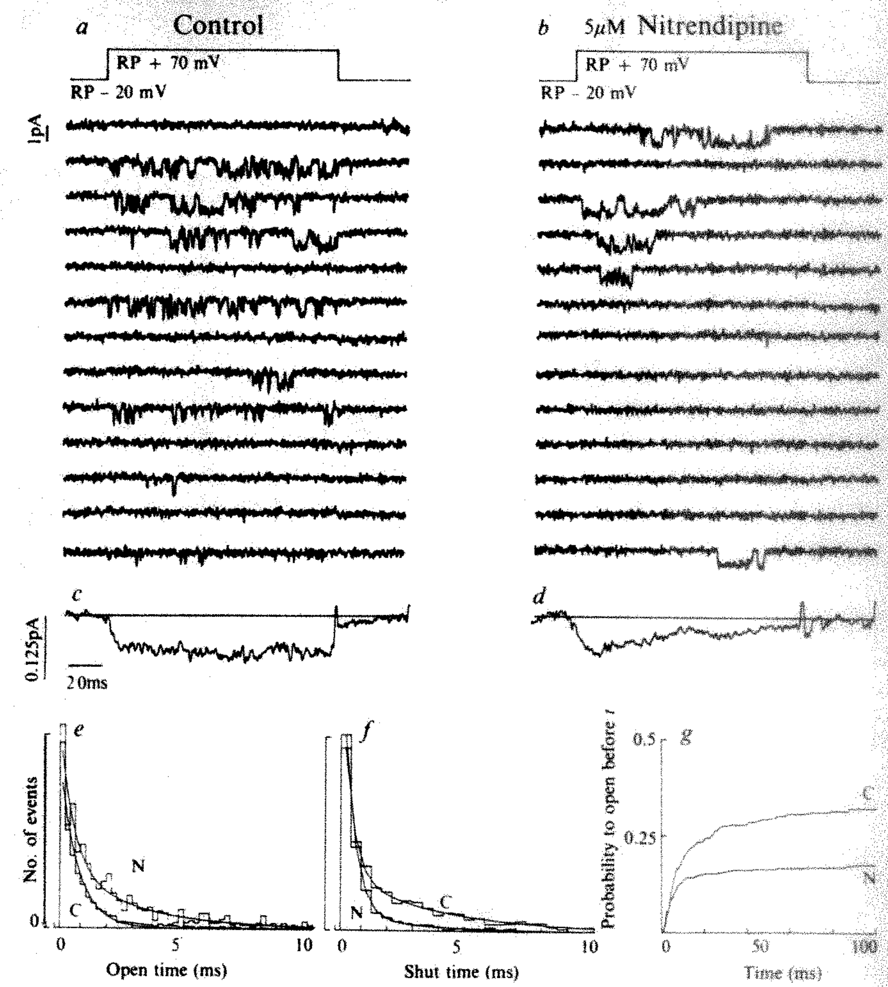

Fig. 6 Effect of nitrendipine on the activity of a single channel. Experimental conditions as in Fig. 2*a*. RP ≈ −60 mv. *a*, *b*, Representative groups of consecutive sweeps in the absence (*a*) and presence of 5 μM nitrendipine (*b*). Voltage clamp protocol shown above the current traces, *c*, *d*, Averaged currents from run *a* (409 sweeps) and run *b* (414 sweeps). *e*, Superimposed distributions of open times. Control data (C) fitted by a single exponential ($T = 0.8$ ms), nitrendipine data (N) fitted by the sum of two exponentials ($T_f = 0.75$ ms, $T_s = 3.2$ ms). Full-scale is 700 and 100 openings for control and nitrendipine respectively. *f*, Superimposed distributions of closed times, fitted by sum of two exponentials (control: $T_f = 0.38$ ms, $T_s = 3.63$ ms; nitrendipine: $T_f = 0.42$ ms, $T_s = 2.57$ ms). Full scale is 600 and 300 closings for control and nitrendipine respectively. *g*, Superimposed cumulative distributions of latencies to first opening. The distribution of open times in nitrendipine (*e*) consisted of a fast exponential component as in control ($T \sim 0.75$ ms), plus an additional slow component. The time constant of the slow component (3.2 ms) falls short of the ~20 ms time constants characteristic of mode 2 activity in control and with Bay K 8644. The cause for this discrepancy is not clear. We cannot exclude the possibility that nitrendipine not only influences the proportion of sweeps the channel spends in mode 2, but also affects the kinetics of opening and closing within mode 2. Another explanation is that openings of nitrendipine-bound channels are cut short by an accelerated inactivation reaction (transition from mode 2 to mode 0), which acts in parallel with the closing reaction within mode 2 (O − C2) and thereby increases the overall closing rate above its normal value.

physical plugging of the Ca channel pore. A simple binding and plugging hypothesis can be excluded since a nitrendipine molecule cannot plug the channel and show agonist-like activity at the same time; separate binding sites for nitrendipine's antagonist and agonist actions seem highly unlikely since Bay K 8644 competes for all of the nitrendipine binding sites[30]. The results point instead to modulation of gating as the mechanism of DHP agonist or antagonist action. The changes in gating revealed by the single channel analysis help to explain earlier observations in single cell or multicellular cardiac preparations. All lines of evidence support the idea that inactivation and the inhibitory effects of DHP Ca antagonists reinforce each other. Thus, (1) nitrendipine speeds the decay of Ba current through Ca channels in both whole cell[27] and unitary current recordings (Fig. 6), as if drug binding promotes mode 0. (A similar acceleration is seen with Bay K 8644 at stronger test depolarizations (Fig. 1), and is tentatively attributed to the drug's partial antagonist action.) (2) Nitrendipine[24] and nisoldipine[28] act to slow recovery from inactivation following a depolarizing pulse. (3) Steady depolarizations that inactivate Ca channels strongly promote nisoldipine's inhibitory effect[28]. (4) Like voltage-dependent inactivation[21,25], the inhibitory effect of DHP antagonists is expressed as an increase in the percentage of empty sweeps at the single channel level (Fig. 6).

Our hypothesis provides a simple explanation of partial agonist or partial antagonist effects, and a framework for classifying the 7,000 or more dihydropyridine compounds that remain less well studied than nifedipine or nitrendipine. It will be interesting to see if any of these molecules behaves as a pure agonist or antagonist, exclusively stabilizing mode 2 or mode 0. It is important to remember that the range of possibilities is not limited to a one-dimensional scale between agonism and antagonism, since stabilization of three modes needs to be taken into account. In addition to the ideal agonist and ideal antagonist, one might imagine a compound that exclusively stabilizes mode 1, and thereby opposes effects of both agonists and antagonists.

The mechanism of transitions between modes is not known. The clustering of mode 2 activity indicates that switching can be relatively slow and raises the question of whether the transition between modes is an expression of a covalent modification of the channel protein. For the moment, we can only say that the modulatory process is probably not cyclic AMP-dependent protein phosporylation, since the effect of agonist is quite different than that produced by elevation of cyclic AMP with isoprenaline[25,27] or 8-bromo-cyclic AMP[22]. Unlike Bay K 8644, isoprenaline slows both the activation and inactivation of Ba currents through Ca channels[18,27] but it does not by itself slow significantly the decay of inward tails[18]; it does not induce mode 2 activity, but it modifies the rate constants within mode 1 (refs 21, 22, 25). Isoprenaline-induced increases in the number of functional channels[18] might be accounted for by a recruitment of channels from mode 0 to mode 1.

Like the cardiac cells described here, sensory neurones from chick dorsal root ganglion and neuroblastoma cells show a mixture of modes 0, 1 and 2, and an enhancement of mode 2 behaviour with Bay K 8644 (refs 31, 32). The apparently widespread existence of the gating modes and their positive response to Ca agonist gives new reason to wonder whether dihydropyridines have endogenous counterpart(s) that up- or down-modulate Ca channels (compare ref. 11).

We thank Drs R. W. Aldrich, C. J. Cohen, A. P. Fox, R. A. Janis, Y. Kurachi, M. C. Nowycky, A. Scriabine and B. Sakmann for helpful discussions, and the USPHS and the Miles Institute for support.

Note added in proof: After submission of this manuscript and publication of preliminary communications of this work[14,31], prolonged openings of cardiac Ca channels in the presence of DHP Ca agonists have been reported[35,36].

Relic interstellar grains in Murchison meteorite

Jongmann Yang & Samuel Epstein

Division of Geological and Planetary Sciences, California Institute of Technology, Pasadena, California 91125, USA

Isotopic analyses of hydrogen, carbon and nitrogen in meteorites provide important information about the origin and history of these elements both in meteorites and in the Solar System. Here we show that, in the Murchison meteorite, the D/H ratios of hydrogen are unusually high in several separates and in one case up to 30 times the cosmic value of 2×10^{-5}. Many phases show high $^{13}C/^{12}C$ ratios, up to 2.5 times the terrestrial value of 0.011. These ^{13}C-rich and D-rich components of the two chemical elements are not correlated. Also they are heterogeneously distributed, suggesting that different components in the meteorite originated from different astrophysical sites and at different times. The D-rich hydrogen in the meteorite is probably due to molecules formed by ion–molecule reactions in interstellar clouds while the tiny amount of ^{13}C-rich carbon is probably due to nucleosynthesis in red giant stars as suggested by Swart *et al.*[1]. Both of these heavy-isotope enriched components survived homogenization in the accumulation and subsequent history of the meteorites.

Following studies of isotopic compositions and concentrations of hydrogen and carbon in acid residues from various types of meteorites, we have shown[2] that: (1) Many primitive carbonaceous and non-carbonaceous meteorites contained HCl–HF insoluble organic matter with high D/H ratios, $>30\times10^{-5}$, suggesting enrichment of deuterium in the molecules by means of isotopic exchange reactions with cosmic hydrogen[3-5] below 150 K. (2) All the meteorites that have been analysed contained inorganic hydrogen which was soluble in HCl–HF solutions. This hydrogen uniformly had a D/H ratio of about 14×10^{-5}, similar to terrestrial hydrogen. This suggests that the D/H ratio in this inorganic component was determined in the solar nebula at a minimum temperature of ~200 K by isotopic exchange reactions between molecules and cosmic hydrogen gas. (3) Three unequilibrated meteorites (Semarkona, Bishunpur and Renazzo) showed another extremely anomalous component of acid soluble organic hydrogen with $D/H \simeq 170\times10^{-5}$, more than 80 times higher than the D/H ratio of cosmic hydrogen. This suggests that meteorites contain organic matter that formed well below 100 K in interstellar clouds before formation of the solar nebula because the temperatures attributed to the solar nebula are much higher than 100 K.

Carbon, on the other hand, showed no obvious ^{13}C anomalies, other than a $\delta^{13}C$ enrichment of about 60‰ due to the presence of carbonates[2,6,7]. δ indicates the variation in isotopic ratios relative to standards in ‰. Standards for hydrogen, carbon and nitrogen are ocean water, PDB and air, respectively. However, a tiny fraction of the carbon, was found to be resistant to various chemical reagents and resistant to combustion below 800 °C. This carbon was a new component in the meteorite and its $^{13}C/^{12}C$ ratio was greater than all carbon previously found on the Earth and in the meteorites[1,8,9]. This carbon has a $^{13}C/^{12}C$ ratio of at least twice that of the Earth.

The aim of the present study was to determine how the new ^{13}C-rich carbon might relate in origin to the D-rich hydrogen and to the $^{15}N/^{14}N$ ratio of nitrogen. Murchison meteorite was powdered and aliquots of the samples were demineralized by reaction with HCl–HF solutions. The resulting residue, designated CF, was then treated with various chemicals to remove certain components of the residue and separated by particle size (see Table 1) to try to concentrate the exotic mineral phases and the interstellar relic grains. Gas samples of hydrogen, carbon and nitrogen were analysed by standard stable isotope ratio mass spectrometric techniques and reported in the usual δ notations.

Concentrations and isotopic data of hydrogen, carbon and nitrogen are given in Table 1. For the bulk sample the hydrogen is dominated by hydrogen from inorganic sources whose δD value is about −50‰. The $\delta^{13}C$ value of the total carbon is about −2.4‰ but the presence of heavier carbon is apparent from the CO_2 given off at the combustion above 500 °C ($\delta^{13}C=27‰$). The D/H data of the CF residue show that all inorganic hydrogen is removed by HCl–HF acid and a deuterium-rich organic material dominates the residue (Fig. 1*a*).

Two residue samples (CFOc, CFOf) resulting from the oxidation of CF residue by reagent H_2O_2 contain an unusually high $^{13}C/^{12}C$ ratio carbon which is oxidized to CO_2 above 800 °C. The $\delta^{13}C$ ranges between 500 and 1,200‰. In principle, such high $\delta^{13}C$ values can be produced by isotope exchange reactions at very low temperatures[10] that exist in the interstellar media. In such circumstances, one might expect that there would be a much greater heterogeneity in the $\delta^{13}C$ values in the organic residues and that a much larger fraction of the organic acid residue would be relatively enriched in ^{13}C. Therefore, it is the tiny amount of ^{13}C-rich component that makes it a good candidate for a red giant origin. On the other hand, large fractions of the organic residues have high δD values. As we have argued previously, such δD values for a large fraction of the organic residues could only be obtained by ion–molecule reactions occuring in the interstellar medium.

The finer grain fraction (CFOf) has a hydrogen and carbon content per gram of bulk meteorite a factor of 10 times higher than the coarser grain fraction (CFOc). Compared with CFOc, CFOf has a higher C/H ratio of 2.76 and a higher $^{13}C/^{12}C$ ratio of up to 0.025 but a lower D/H ratio by a factor of two. Perhaps
